National Aeronautics
and Space Administration
Scientific and Technical Information Branch

Aerodynamic characteristics obtained in a rotational flow environment utilizing a rotary balance located in the Langley spin tunnel are presented in plotted form for a $1 / 5-s c a l e$, single-engine, low-wing, general aviation airplane model. The configurations tested included the basic airplane, sixteen wing leading-edge modifications and lateral-directional control settings. Data are presented for all configurations without analysis for an angle-of-attack range of $8^{\circ}$ to $35^{\circ}$ and clockwise and counter-clockwise rotations covering an $\frac{\Omega b}{2 V}$ range from 0 to 0.85. Also, data are presented above $35^{\circ}$ angle of attack for some configurations.

## INTRODUCTION

The NASA Langley Research Center has initiated a broad general aviation stall/spin research program which includes spintunnel and free-flight radio control model tests, as well as full-scale flight tests for a number of configurations typical of light, general aviation airplanes. To support this effort, rotary balance wind tunnel force tests covering these same configurations will be conducted to establish a data base for analysis of model and full-scale flight results, and to develop design charts for desirable stall/spin characteristics.

A $1 / 5$-scale, single-engine, general aviation airplane model, referred to as model $A$, having a low-wing location was tested in a rotational flow environment utilizing a rotary balance located in the Langley spin tunnel. This report presents the data obtained for the basic configuration, sixteen wing leading-edge modifications, and lateral-directional control settings.

The units for physical quantities used herein are presented in the International System of Units (SI) and U.S. Customary Units. The measurements were made in the U.S. Customary Units; equivalent dimensions were determined by using the conversion factors given in reference 1.
b wing span
$\overline{\mathrm{c}}$ mean aerodynamic chord, cm (in.)
$C_{L}$ lift-force coefficient, $\frac{\text { Lift force }}{\text { qS }}$
$C_{\ell}$ rolling-moment coefficient, $\frac{\text { Rolling moment }}{q S b}$
$C_{m}$ pitching-moment coefficient, $\frac{\text { Pitching moment }}{\text { qS }}$
$C_{n}$ yawing-moment coefficient, $\frac{\text { Yawing moment }}{\text { qSb }}$
$q$ free-stream dynamic pressure, $N / \mathrm{m}^{2}\left(1 \mathrm{~b} / \mathrm{ft}^{2}\right)$
$S$ wing area, $m^{2}\left(f t^{2}\right)$
V free-stream velocity, m/sec (ft/sec)
$\alpha$ angle of attack, deg
$\beta \quad$ angle of sideslip, deg
$\Omega \quad$ angular velocity about spin axis, rad/sec
$\frac{\Omega \mathrm{b}}{2 \mathrm{~V}}$ spin coefficient, positive for clockwise spin
$\delta_{a}$ aileron deflection, positive when right aileron is down

$$
\left(\delta_{a_{\text {right }}}{ }^{-\delta} a_{\text {left }}\right) / 2, \operatorname{deg}
$$

$\delta_{e}$ elevator deflection, positive when trailing edge is down, deg $\delta_{r}$ rudder deflection, positive when trailing edge is to left, deg

LE leading edge
SR spin radius

TEST EQUIPMENT
A rotary balance measures the forces and moments acting on an airplane while subjected to rotational flow conditions; the background for this apparatus is discussed in reference 2. A photograph and sketch of the rotary balance apparatus installed in the Langley spin tunnel are shown in figures 1 and 2 , respectively. The rotating portion of the balance system, mounted on a horizontal supporting boom which is hinged at the wall, is moved from the wall to the center of the tunnel by cables. The rotary arm of the balance system, which rotates about a vertical axis, is attached to the outer end of the horizontal supporting boom and is driven by a drive shaft through couplings and gears.

A test model is mounted on a strain gauge balance which is affixed to the bottom of the rotary balance apparatus. Controls located outside the tunnel are used to activate motors on the rig which position the model to the desired attitude. The angle-ofattack range of the rig is 8 to 90 degrees and the sideslip angle range is $\pm 15$ degrees. The spin radius and the lateral displacement motors allow the operator to position the moment center of the balance on the spin axis or at a specific distance from the spin axis. This is done for each combination of angle of attack and sideslip angle. The general practice is to mount the moment center of the balance at the cg location about which
the aerodynamic moments are desired. Electrical current from the balance, and to the motors on the rig, is conducted through slip-rings located at the rig head. Examples of how the rig is positioned for different angle of attack and sideslip angles are shown in figures $2 a$ and $2 b$, respectively.

The model can be rotated up to 90 rpm in either direction. By using different rotational speeds and a specific airflow in the tunnel, the motions of a steady spinning airplane can be simulated. The aerodynamic forces and moments can then be measured for values of $\frac{\Omega \mathrm{b}}{2 \mathrm{~V}}$, including the case of $\frac{\Omega \mathrm{b}}{2 \mathrm{~V}}=0$, where static aerodynamic forces and moments can be obtained.

A NASA six-component strain gauge balance is mounted inside the model and measures the normal, lateral and longitudinal forces and the yawing, rolling and pitching moments acting about the model body axis. The interactions that exist between the six components are available from balance calibration tests and are accounted for after the balance voltages are converted to forces and moments.

The data acquisition, reduction and presentation system for the rotary balance set-up is composed of a l2-channel scanner/ voltmeter, a mini-computer and a plotter. With this equipment, on-line digital print-out and/or graphical plots of data are possible.

## TEST PROCEDURES

Rotary aerodynamic data are obtained in two steps. The first step is to record the inertial forces and moments (tares) acting on the model at different attitudes and rotational speeds.

To accomplish this, a covered bird-cage like structure is mounted to the upper rig which encloses the model without touching it. In this manner, the air immediately surrounding the model is rotated with it. As the rig is rotated at the desired attitude and rate, the inertial forces and moments generated by the model are measured and stored on magnetic tape for later use.

The second step in the data-gathering process is to measure aerodynamic and inertial forces at different attitudes and rotational speeds for a selected tunnel velocity with, of course, the cage structure removed. The tares are subtracted from these values, and the remaining aerodynamic forces and moments are then converted to coefficient form and stored on magnetic tape.

MODEL
A l/5-scale fiberglass/aluminum model of a configuration considered to be a typical low-wing, single-engine, light general aviation airplane was tested in the present study. A three-view drawing of this model is shown in figure 3 , dimensional characteristics of the model are presented in Table $I$, and a photograph of the model installed on the rotary balance located in the Langley spin tunnel is presented in figure 1.

The model control surfaces could be set at any position prior to the test. The maximum deflections for the control surfaces were:

$$
\begin{array}{ll}
\text { Rudder, deg } & 25 \text { right, } 25 \text { left } \\
\text { Aileron, deg } & 25 \text { up, } 20 \text { down }
\end{array}
$$

The tests were conducted in the spin tunnel at a tunnel velocity of $7.62 \mathrm{~m} / \mathrm{sec}(25 \mathrm{ft} / \mathrm{sec})$ which corresponds to a Reynolds number of 128,000 based on the model mean aerodynamic chord. Unless noted otherwise in Table II, all the configurations were tested through an angle-of-attack range of 8 to $35^{\circ}$ at a zero sideslip angle with the spin axis located 76.2 cm (30in) forward of the full-scale airplane cg location of $.255 \overline{\mathrm{c}}$. At each spin attitude, measurements were obtained for nominal $\frac{\Omega \mathrm{b}}{2 \mathrm{~V}}$ values of $.1, .2, .3, .4, .45, .55, .65, .75$ and .85 in both clockwise and counter-clockwise directions, as well as for $\frac{\Omega \mathrm{b}}{2 \mathrm{~V}}=0$ (static value).

## DATA PRESENTATION

Table II identifies the configurations tested and the corresponding appendix figure numbers which present the aerodynamic data. The aerodynamic coefficients vs. $\frac{\Omega \mathrm{b}}{2 \mathrm{~V}}$ are presented for each configuration in three sequentially numbered figures in the following order: $C_{n}, C_{\ell}$, and $C_{m}$. Each figure, in turn, consists of two pages which present the subject aerodynamic coefficient vs. $\frac{\Omega \mathrm{b}}{2 \mathrm{~V}}$ for the following angles of attack and spin radius.
a) $\alpha=8,10,12,14,16 \mathrm{deg} \quad \mathrm{SR}=76 \mathrm{~cm}$ (30in)
b) $\alpha=18,20,25,30,35 \mathrm{deg} \quad \mathrm{SR}=76 \mathrm{~cm}(30 \mathrm{in})$

As noted in Table II, data is also available for some configurations between 30 and $90^{\circ}$ angle of attack. This data is presented for the following angles of attack and spin radius:
c) $\alpha=30,35,40,45,50 \mathrm{deg} \quad \mathrm{SR}=0$
d) $\alpha=55,60,70,80,90$ deg $\quad S R=0$

All the moment data are presented for a cg position of 0.255 .
Lift coefficient as a function of angle of attack for zero rotation rate is presented at the end of the Appendix for the configurations cited in Table II.
