Scope of Work

Motorola contracted to screen 125 transistors capable of withstanding the high level inductive voltages obtained when switching inductive loads. The transistors were to be similar in performance to those delivered to Rockwell International for application in the SSME Spark Igniter System, i.e. Rockwell Specification RES1075.

Planned differences included a change in die bonding to comply with NASA's desire for hard solder die attachment which further necessitated a change in package to conform to the required die mounting system. Evaluation of the electrical performance and recommended changes were to be made during the preliminary build phase of the program.

Device Description

Die: NPN, double diffused-epitaxial collector;
glassivated mesa, 190 x 190 mils.

Package: TO-8, steel, molybdenum heat spreader,
gold plated, glass feed-thru's.

Construction: Gold eutectic die attachment,
10 mil Mag-Alum wires, ultrasonic
bonding on die, tweezer weld on posts.

Test Plan and Results

The Special Device Specification 48ARB64845A (SJ6708H) was written to provide internal Motorola control of processing and screening of devices in accordance with the NASA contract. A copy of this specification is included in Section C.

The sequence of testing and test result summary is contained in the Customer Data Summary Sheet in Section B. The documentation of data readouts is indexed and grouped in Section F.

Test equipment used in the testing and screening of these devices is listed in the Test Facility List of Section E.

The first problem encountered was an instability of the die after 100% high temperature reverse bias when 56 of 160 devices failed the electrical inspection (reference R.O. #10). The remaining 104 devices went to 100% Burn-In (49 devices were designated Group B-6 samples and 168 hr. endpoints were recorded on a separate tab run; i.e. R.O. #55). Nine devices failed after 168 hrs., eight in the standard 100% group and one in the B-6 group, but the remaining devices were stable thru the 2000 hr. B-6 test.

The second problem encountered was hermeticity failures (22 pcs) in the B-1 test sample. This sample had been submitted to Thermal Shock (Glass Strain) test and Terminal Strength test prior to the hermeticity test. These prior tests apparently damaged the glass to metal seals as indicated in the Failure Analysis Report PL-099 #034 contained in Section D. In order to determine the specific test causing the glass seal damage, a separate sample was run through B-1 again with a hermeticity check made after each mechanical test (see Pg. 10 Special Test in Customer Data Summary). The mechanical stress of the Terminal Strength test was determined to be the primary cause of seal failure.

A computer readout problem became evident in the final measurements of Group B testing. A number of devices showed low or no readings at all on BVCES, while the other measured parameters had normal values. An analysis of the Lorlin equipment showed a tendency for oscillations with these devices during the high voltage test resulting in low readings or no printout. All the BVCES failures were retested and observed on a curve tracer. Other than the tendency to oscillate at breakdown, the devices checked normal and within specification limits.

In Group B, subgroup VI, one device (S/N 21) showed no beta reading at 1500 hrs. The device beta measured 19.98 on verification test, a change of -5.6% from the initial reading. The device was sent to Failure Analysis for review. No evidence of a failure mechanism was found but the device was delidded and chemically etched during the analysis so it could not be returned for the last 500 hours of test. Since no problem was found in the device, we did not list it as a failure. There were sufficient spare devices in the test to maintain the correct sample size.

Conclusions:

Two major problems developed during the screening of the contract devices, (1) die instability, as evidenced by the high-temperature reverse-bias failures and (2) poor glass to metal seals in the mechanical package, as evidenced by the inability to pass the specified terminal strength test.

The mechanical package problems in screening surfaced again in subgroup I of qualification (Group B) testing. Oscillation problems at the computer caused a significant number of "bad" endpoint readings in other Group B subgroups but re-test and failure analysis indicates there were no subgroup failures.

The instability problem is a serious but not uncommon problem on high voltage devices. Significant improvements in lot to lot stability were achieved by the addition of glassivation to the exposed mesa junctions. This type glassivation was used on these contract devices to try to achieve maximum stability but as demonstrated in this effort, mesa glassivation alone is not always successful. Since the inception of this contract, considerable work has been in process on this problem due to similar failures on standard production lots. Our studies indicate that additional glassivation protection is needed over the basically planar emitter base junction. This technique has recently been incorporated into production with a marked improvement in the probability of die lot stability.

Another significant cause of instability in high-voltage die is the temperature effect on silicon resistivity. A number of theoretical and experimental studies have been published showing that resistivity peaks at a critical temperature for each doping concentration. Operation in the temperature region above the maximum resistivity can result in a run away condition. The maximum resistivity temperature for 50 ohm-cm material is about 160°C. The critical temperature decreases with increasing resistivity. The material used on this contract had resistivity in the range of 40 to 80 ohm-cm and the HTRB test temperature was run at 150°C. We believe that the high failure rate in HTRB can be, at least partially, attributed to the higher resistivity devices operating over their critical temperature.

The glass to metal seal problem is a vendor problem normally resolved by qualifying packages and vendors through Motorola's Manufacturing Engineering Department prior to a production commitment. At the time of this contract, Motorola did not have any production requirement for TO-8 hard-solder packages and therefore had no qualified vendors for such a package. The package used on this contract was obtained from the only available source of production TO-8 packages at that time. A full package qualification was not included or contemplated as part of this effort.

Recommendations:

As a result of this activity, Motorola recommends some changes in this device for future applications. The same mask and basic process design should be used but with lower resistivity material (25 to 40 ohm-cm) and the added protection of base/emitter passivation. This revised configuration has been submitted to extensive HTRB evaluation with good parametric stability results. Motorola is planning to use this revised die configuration to qualify the 2N6308 under MIL-S-19500/498. A major computer manufacturer is presently qualifying this die for their product line, and it is presently being used for a new procurement of the Rockwell International RES1075.

Motorola also recommends that future applications of this device be procured in a steel TO-3 package instead of the TO-8 package. If mounting space is a serious consideration, a steel TO-66 package would be our next recommendation. A production requirement for the TO-8 package would require an extensive qualification of packages and suppliers. The TO-8 package is not used extensively for silicon devices. The TO-3 package is the most widely used package in the transistor industry. It is continually tested for reliability through JAN products, high reliability specials and user reliability programs. This is also true of the TO-66 but to a less degree because it is used in smaller quantities. The computer and MIL product will be built in the TO-3 package. Due to prior design commitments, the Rockwell device is being made in a TO-8 package but a new package source was located for this build.

NOTES

4. DATA REQUIREMENTS:

4.1 Motorola shall retain one copy of all data for a period of three years from date of P.O.

4.2 Data to ship with Devices:

4.2.1 C of C for internal Visual Inspection (Step 0.1)

4.2.2 Summary Data for 100% Processing, Group A and B Inspections (Step 2.2, 2.3, and 2.4).

4.2.3 All variables data and delta calculations for 100% Processing and Group B Inspections (Steps 2.2 and 2.4).

4.3 Final Report

4.3.1 Three draft copies of the Final Report shall be submitted to the Customer for approval prior to Final Printing and Distribution.

4.3.2 The Final Report shall contain the following:

a) A detailed description fo each test setup with identification of critical test equipment, test circuit diagrams and procedures.

b) A narrative discussion of test results, conclusions, and recommendations.

c) Measurement data, and as applicable, Tables, Graphs, Diagrams, Sketches, Curves, Procedure Photographs and Drawings.

As part of the Final Report, Motorola shall also complete and submit to MSFC Government Industry Data Exchange Program (GIDEP) Form 2:11-72.

4.3.3 Following approval of the Final Report by the Customer, 15 copies shall be sent per the distribution list furnished by the Customer.

| | | |

NOTES (Continued)

5. SHIPPING INSTRUCTIONS:

- 5.1 Customer Program Manager shall be notified prior to shipment of Test Samples (DD250 forms must be supplied).
- 5.2 Tray pack per MIL-S-19491, Level C.
- 5.3 Package Salt Atmosphere Test Samples separately and mark package "SALT ATMOSPHERE (Corrosion) TEST SAMPLES."

6. GENERAL NOTES:

- 6.1 Marking Instructions: Mark Devices with 04713, SJ6708H, Date Code per MIL-S-19500, RES1075-01(1), and Serial Number.
- 6.2 The following deviations to customer print Request # 8-1-T-EC-06242, Exhibit A, are authorized per TWX from H. Garrett, NASA to W. Albertin, Motorola, dated 7-18-77. (Copy of TWX on file with SAR for issue 0 of this specification.)
 - 6.2.1 TABLE III, hFE4 shall be 7 min.
 - 6.2.2 TABLE III, ES/B shall be 125 mJ min.
 - 6.2.3 TABLE III, hFE1 shall be @ VCE = 3V.
 - 6.2.4 FIGURE 3: changed resistor values for tf test only.
 - 6.2.5 Burn-In and Operation Life shall be performed concurrently.
 - 6.2.6 Revised FIGURE 2.
 - 6.2.7 TABLE IV: Operation Life test samples (40) shall not include samples (20) that had Acoustic tests. A test to Burn-In end points shall be performed after 168 hours of Operation Life test.

BACKGROUND:

Eight transistors in a flangeless TO-66 package (TO-8) with three 0.030" leads approximately 0.5" long were submitted for analysis because of hermeticity problems. The transistors contain a 5 RV 190 mil² chip mounted on a molybdenum heat spreader approximately 0.008" thick. Connections are of aluminum wire, 10 mils in diameter. All transistors have multiple bends in all three leads. These transistors were to find application in the Space Shuttle.

INVESTIGATION:

A cursory visual examination with a 10X lens revealed severe damage to the glass to metal seal in all transistors. They were subjected to a gross leak test utilizing dye penetrant and experienced 100% failure. A closer examination of the devices with the scanning electron microscope (Photos 1-5) demonstrated severe damage to the glass-to-metal seals. The quality of the glass in the feed throughs seemed to be normal. All leads exhibited movement with respect to the seal glass (Photo 4) in a direction away from the header, indicating damage was almost certainly induced by a pull on the lead. Checking of the lot history of these devices revealed they did experience a pull test according to MIL-STD-740, method 2036, where a 10 lb weight is suspended from the package for 15 seconds. Reports also indicate that 100% failure of a 20 piece sample of these parts, subjected to hermeticity checking did occur after lead tensioning test.

CAUSE:

Insufficient metal-to-glass seal integrity resulted in poor resistance to the lead tensioning test, cracking the glass, and causing failure of the devices to remain hermetic.

RECOMMENDATION:

This TO-8 package is not recommended for devices intended for use in the aerospace environment.

Device #13 was submitted on a N.O.D. following unloading. A preliminary electrical check proved the device to be good. A subsequent electrical check in the unloading area again proved the device to be good.

Cause for the N.O.D. at unloading is unknown at this time.

BACKGROUND:

Three units were submitted after 2000 hours of op life testing. Unit 21 was reported as an E-B short at unloading. Units 4 and 69 were limit rejects on the post 2000 hour read out.

INVESTIGATION:

A parameter check found unit #4 to be good while units 21 and 69 were marginally low on hFE_3 (19.6, 19.4 - min 20).

Microscopic inspection of #21 after delidding and chemical etching disclosed no evidence of a failure mechanism that would cause an E-B short.

No further analysis was performed on unit #69.

CAUSE:

Unit #4 was found to be good.

Units 21 and 69 were marginally out of spec. and the failure mechanism is unknown at the present time.
