Technical Note 78-4

USSR Spring and Winter Wheat Models

Revised 1978

Clarence Sakamoto, Sharon LeDuc, and Arno Perlow<sup>1</sup>

With the experience of LACIE (Large Area Crop Inventory Experiment), a joint project involving NASA, USDA, and NOAA, it was determined that some of the models (in CCEA Technical Note 77-2, "Wheat Yield Models for the USSR," May 1977) were not performing satisfactorily. Associated problems included: 1) misspecification of trend term and 2) revision of meteorological variables that were considered significant. Consequently, all the models were reviewed with the objective of improving the response of the model. In particular, the covariance models were separated, where possible, with the inclusion of additional data years.

The philosophy of this revision with respect to trends where they exist in the data series is that this surrogate for technology varies throughout the Soviet Union, with trends still increasing in some regions having stabilized in others.

The separation of the covariance models seems to have improved the performance of the estimated yield in the jackknife test. This is the test adopted by LACIE to test the yield model with a relatively short period of record. In this approach, one year from the data set is selected as the independent test year while the remaining years are used to develop the coefficients of the regression model. This procedure is done for ten consecutive years.

Detailed explanation of the variables and their derivation is provided in Technical Note 77-2. The reader is referred to this publication.
