AN INVESTIGATION OF WING BUFFETING RESPONSE
AT SUBSONIC AND TRANSONIC SPEEDS:
PHASE I F-111A FLIGHT TEST DATA ANALYSIS

VOLUME III: TABULATED POWER SPECTRA

by

David B. Benepe, Atlee M. Cunningham, Jr.,
and W. David Dunmyer

SUMMARY

The structural response to aerodynamic buffet during moderate to high-g maneuvers at subsonic and transonic speeds was investigated. The measurements which consisted of shear, bending moment and torque at four wing span stations, vertical accelerations at the wing tips, center of gravity and pilot's seat had been previously obtained during the Loads Demonstration flight program on a variable sweep fighter-bomber aircraft.

Existing flight data for one wing sweep were extracted from magnetic tape records and subjected to statistical analyses to determine the power spectra and root-mean-square values of response for each of the measurements at several angles of attack for each of seven maneuvers. The frequency content of the various responses was correlated with results of ground vibration tests to identify the response modes. The rms values of response were plotted against angle of attack to show the variations of intensity of response during the maneuvers.

The Phase I F-111A Flight Data Analysis effort is reported in three volumes. NASA CR-152109 presents a summary of the technical approach, the results and conclusions drawn from the results. NASA CR-152110 presents plotted variations of Power Spectral Density (PSD) data with frequency for each structural response item for each data sample analyzed during the course of the investigation. NASA CR-152111 presents Power Spectral Density (PSD) data in tabular form for the convenience of those who might wish to perform additional analysis.

SYMBOLS

Note: Quantities are presented in the International System of Units (U.S. customary units in parenthesis). The work was performed using U.S. customary units.

b	wing span - m, (ft)
c.g., C.G.	center of gravity
f	frequency, hertz
f_0	spectral base frequency or analysis bandwidth, hertz
F_Z	wing vertical shear as measured by strain gages - N, (lb)
g	gravitational acceleration
M	Mach number
M_X	Wing Bending Moment as measured by strain gages - N-m, (in-lb)
M_Y	Wing torsional moment - N-m, (in-lb)
S	theoretical wing area (leading and trailing edges of swept panel extended to airplane centerline)- m^2 , (ft ²)
ΔT	length of input frame in spectral analysis - seconds
T_1	start time of interval for spectral analysis- seconds
T_2	stop time of interval for spectral analysis - seconds
\dot{y}	lateral acceleration - g's
\dot{z}	vertical acceleration - g's
α	indicated angle of attack referenced to wing manufacturing chord plane
α_{max}	maximum indicated angle of attack - deg.
α_{nom}	nominal angle of attack representing time interval ΔT

SYMBOLS, (Continued)

α_1	indicated angle of attack at time T_1 , deg.
$\Delta\alpha$	increment in indicated angle of attack during time interval ΔT , deg.
β	indicated sideslip angle, deg.
σ_a	rms value of acceleration fluctuations - g, rms
ψ_T	average rms value determined from power spectral analysis

SECTION 1

INTRODUCTION

The phenomenon of aerodynamic buffet has been a challenge to aircraft design teams for many years. With the advent of truly high performance fighter aircraft which are capable of operating at high angles of attack, the intensity of buffet and the magnitudes of the aircraft structural responses to buffet have become important design considerations.

The state-of-the-art of buffet research is such that development of a valid method of predicting aircraft structural response to buffet appears feasible in the near future. A significant problem that exists is the dearth of published flight data to provide an adequate test of the validity of a prediction method.

This investigation, described in NASA CR-152109, NASA CR-152110, and NASA CR-152111, supplies data of sufficient scope in terms of the number and types of flight measurements and in terms of the depth of analysis of the measurements to use for correlation with predicted response characteristics. A secondary, though no less important, objective of the investigation is to add to the aeronautical community's understanding of buffet phenomena which has advanced rapidly in recent years.

Considerable effort has been expended in research programs conducted by the National Aeronautics and Space Administration's

Ames, Langley, and Flight Research Centers (Refs. 1-7), by the armed services (Refs. 8-14), and by airframe manufacturers (Refs. 15-17). Each of these previous efforts has contributed something of significance to our understanding of buffet and of aircraft responses to buffet.

Results of various flight test programs have shown that a most reliable indicator of maneuvering buffet onset is the abrupt change in rms response of a wing-tip accelerometer. It can also be inferred that wing-tip accelerometer response is a good indicator of the variation of buffet intensity with angle of attack. However, measurements need to be obtained of accelerations at several points on an aircraft and of the spanwise distributions of dynamic structural loads on the wing to obtain a true test of a prediction method. Additionally, power spectra data are needed for each measurement over a range of frequencies which covers the important natural vibration modes of the aircraft structure.

Recent developments in flight test instrumentation and data recording and data processing systems permit the use of powerful techniques of random data analysis to study the buffet problem. Power spectral density (PSD) plots can be readily constructed to obtain the needed variations of response with frequency and calculate root-mean-square values (rms) of the accelerations and loads to obtain statistical measures of the variations of responses with angle of attack.

The duration of the flight maneuvers is short, therefore the data samples are usually not long enough to strictly satisfy the mathematical criteria for obtaining a high level of confidence in the spectral or rms estimates. Nevertheless, spectral estimates and rms values are much more meaningful quantities than the peak-to-peak or half-amplitude measurements prevalent in early studies of the buffet problem.

This volume presents tabulated values of Power Spectral Density data in the frequency range from 1 to 100 hertz for each structural response item for each data sample analyzed during the course of the investigation. Some of the information contained in NASA CR-152109 is repeated to allow the reader to identify the specific conditions appropriate to each tabular listing and to perform additional analysis if desired.

The flight program from which data have been extracted for use in this study was primarily for F-111A flight loads demonstration. The test aircraft was therefore instrumented with numerous strain-gage sensors and accelerometers. Flight maneuvers included wind-up turns, pull-ups and roller coasters at various altitudes, Mach numbers, and target load factors. While it was not a particular goal of the flight program to investigate buffeting, many of the flight test conditions were such that significant levels of buffeting occurred. An opportunity thus existed to subject

the extensive flight data to analyses specifically aimed at providing detailed buffeting response characteristics.

The basic approach used in the study is described in the following paragraphs.

The various records pertinent to the Flight Loads Demonstration program were surveyed to identify candidate flight points for the investigation. About 90 combinations of wing sweep, Mach number, altitude and target load factor were selected for initial investigation. Analog strip-charts of thirty items of instrumentation were then made for each candidate flight point. The strip charts were used primarily to identify the particular flight maneuvers in which the wing responses were of sufficient magnitude to be meaningful in the study and to eliminate points in which excessive wing spoiler activity might "contaminate" the response data.

Since the investigation was aimed at providing flight data for comparison with predictions an additional criterion in the selection of flight points for detailed analysis was the existence of corresponding wind tunnel data in terms of wing sweep and Mach number. The investigation finally was concentrated on seven flight maneuvers all of which were performed at one nominal wing sweep. Existing digital data for the selected flight points were then reviewed and plots were made of the variations of Mach number, angle of attack and load factor as functions of time during the

particular maneuvers. Specific time intervals corresponding to nominal average angles of attack were selected for each maneuver and stochastic (statistical) analyses were performed on the outputs from seven accelerometers and twelve strain-gage sensors for each selected time interval.

The major effort in the stochastic analysis was devoted to obtaining power spectral density (PSD) plots as a function of frequency and root-mean-square (rms) values of the magnitudes of wing shear, bending moment, and torque at four wing span stations and accelerations at the wing tips, center of gravity and pilot's seat. These PSD and rms data are essential for correlation with prediction methods. In addition the PSD plots were used to identify the frequencies and magnitudes of the major responses for each time interval. The particular vibration modes associated with the major responses were then identified insofar as possible from the results of extensive ground vibration tests performed at an earlier time of F-111A aircraft (References 18 and 19).

The variations of rms values of the various outputs (for specific ranges of frequencies) of instrumentation were plotted against angle of attack and comparisons made to observe trends with changes of altitude or Mach number.

SECTION 2

AIRCRAFT DESCRIPTION

The test aircraft was F-111A Number 13. A drawing showing the general features of the aircraft is presented as Figure 1. Detailed geometry associated with the aircraft and its components appears in Table 1. The aircraft has a variable sweep wing and a convention was adopted early in the development program that all aerodynamic coefficients would be referenced to geometric characteristics at a specific wing sweep, namely, $\Lambda_{LE}=16$ degrees. The variations of some key geometric characteristics of the wing with leading-edge sweep angle are presented in Figure 2.

Although the aircraft is fitted with a high lift system consisting of multisegment leading-edge slats and multisegment double-slotted trailing-edge flaps, these devices were in their retracted positions for all maneuvers analyzed in this study.

Two-segment upper surface spoilers on each wing are used at low wing sweeps in addition to differentially controlled all-movable horizontal tails to achieve roll control.

The aircraft has a three-axis stability augmentation system which was operational on all maneuvers analyzed in this investigation.

SECTION 3

AIRCRAFT INSTRUMENTATION

The instrumentation system installed in the aircraft consisted of two 30 track and one 14 track FM analog magnetic tape recorders and various transducers throughout the airplane. IRIG B time reference signals were recorded on each tape recorder to provide time correlation. The general locations of the accelerometers pertinent to the buffet study are shown in Figure 3. The actual locations in terms of aircraft geometry references are listed in Table 2.

The characteristics of the accelerometers, most of which were commercially available units, are indicated in Table 3. The accuracies quoted refer to the nominal flat frequency response up to the limit frequency quoted. No calibration data exist above the quoted limit of flat frequency response, however, the natural resonant frequencies are well beyond 100 hertz for all of the accelerometers. There is no reason to suspect a significant deviation from the basic calibration factors quoted for frequencies up to 100 hertz.

The locations of the strain gage sensors pertinent to the buffet study are shown in Figure 4. Shear, bending moment and torque were measured at each of the four indicated wing stations on the right wing. The sensitivities of these measurements were governed by the fact that the wing loads were to be measured

during maneuvers at load factors up to the maximum capability of the aircraft. As a consequence the signal-to-noise ratios for the present buffet studies were lower than is desirable. The calibration slopes for each channel of information are shown in Table 4.

In several cases the frequency response upper limit for the measurements was set by the subchannel characteristics of the flight recording system. Table 5 lists the appropriate nominal limit of frequency response for each item of instrumentation based on the recorder subchannel arrangements for each flight selected for detailed analysis.

Correlating items such as angle of attack, airspeed, Mach number, altitude, gross weight, and control surface positions indication of the spoilers and horizontal tail surface deflections were also recorded on the FM tapes.

A special test nose boom was fitted to the aircraft to obtain angle of attack, sideslip angle, altitude and Mach number data.

SECTION 4

BASIC DATA PROCESSING METHODS

During the Loads Demonstration Flight Program, the FM analog magnetic tapes containing raw flight test data were processed by automated techniques. The real time data were first displayed on strip chart recorders for instrumentation verification. Next, the data were digitized at sample rates of 1 to 20 samples per second under computer control. The specific sample rates depended on user group requirements. The digitized data were then scaled, calibrated and output in computer listings and computer tapes for additional processing on an IBM System/360. Second generation computer runs were made to obtain corrected flight condition data such as gross weight, Mach number, altitude, dynamic pressure and fuel distribution at 1-second intervals.

Microfilm records of the computer listings from the original flight program data reduction were used in the present program to make plots of angle of attack, normal load factor, Mach number and dynamic pressure as functions of flight time and to identify the gross weights and altitudes for the selected flight maneuvers. The Mach number, altitude and dynamic pressure data include corrections for position error. The angles of attack are indicated angles and do not include the effect of upwash at the nose boom.

The following equation formula can be used to obtain an estimate of the true geometric angle of attack values if desired:

$$\alpha_T = 0.318 + 0.931 \alpha (\text{degrees})$$

This correction was not applied to the data presented in this report because the magnitude is not large in the range of angles of attack covered by the flight data and is within the uncertainty of the flight measurements taken under buffeting conditions with an aeroelastic aircraft.

SECTION 5

FLIGHT CONDITIONS SELECTED FOR DETAILED ANALYSIS

The seven maneuvers selected for detailed analysis are listed in Table 6. They consist of two wind-up turns, four pull ups and one roller coaster, all performed at a nominal wing sweep of 26 degrees. The Mach numbers are approximately 0.70, 0.80, and 0.87 for the three high altitude maneuvers (above 6000 meters). At the two higher Mach numbers the selected maneuvers are for three altitudes, nominally 1500, 3700 and above 6000 meters. The gross weights range from 266,000 N to 330,550 N.

Variations of angle of attack, load factor, Mach number and dynamic pressure with flight time are presented in Figure 5 for each of the selected maneuvers. Inspection of Figures 5(a) through (g) shows the wind-up turns are gradual maneuvers, whereas the pull ups and roller coaster are rather abrupt maneuvers. As a consequence, it was feasible to select more points within each of the wind-up turns for stochastic analysis than for the other maneuvers.

Table 7 lists the segments of each maneuver selected for detailed analysis. In most cases the time duration of the records is one second, but some longer records were used particularly for the wind-up turn of Flight 77, S&C-R. The table also lists the indicated angle of attack at the start of each record (α_1), at the

end of each record (α_2) and in a few cases the maximum indicated angle of attack (α_{\max}) occurring during the record. Also presented is the increment in angle of attack during the record ($\Delta\alpha$) which is relatively large for the pullup and roller coaster maneuvers. A nominal angle of attack (α_{nom}) has been assigned to each segment which is used later to plot trends in the variations of instrument responses with angle of attack.

An adjunct to the point selection process was the determination of the buffet onset characteristics for each of the maneuvers from the time histories. The criterion used for buffet onset was the first detectable change in level of response from any of the wing instrumentation which was followed by an ever increasing level of response. The results of the buffet onset determinations are presented in Figure 6. It was possible to obtain buffet onset points for six of the seven maneuvers. The aircraft was slightly into buffet even at 1-g trim conditions for Flight 78, Run 4. Figure 6(a) shows that the variation of angle of attack for buffet onset with Mach number is smooth despite the significant differences in dynamic pressure and pitch rates for the various maneuvers. Figure 6(b) shows that the normal force coefficients for buffet onset show a slight trend of increasing with a decrease in altitude (increase in dynamic pressure). This result is likely due to the fact that less horizontal tail deflection is required to produce the maneuvers at the lower altitudes.

SECTION 6

STOCHASTIC ANALYSIS TECHNIQUES

The analysis techniques used in this study are compatible with American National Standard (ANS S2.10-1971) recommended methods for analysis and presentation of shock and vibration data. A quick-look examination was performed on each time-history measurement to determine the data classification, degree of stationarity, record length, and recoverability.

Measurements

Data reduction was performed on the following data:

1. Shear, bending moment, and torsion at four wing stations (12 measurements).
2. Two wing-tip accelerometers (vertical).
3. Two C.G. vertical and one C.G. lateral accelerometers.
4. Pilot seat vertical and lateral accelerometers.

The analysis performed on these items consisted of PSD (including an average rms value), cross-PSD, and Probability Density and was distributed as follows:

PSD (all items)	779 plots
Cross-PSD (AW001 and AW002)	7 photographs
Probability Density	126 photographs

In addition to the plots and photographs, a digital magnetic tape recording was made of spectral coefficients of all PSD's and

Cross-PSD's. The magnetic tape format (shown in Figure 7) for a single PSD consists of two adjacent records; the first record for identification and the second for raw data.

Special-Purpose Processing

A block diagram of the special-purpose stochastic equipment is shown in Figure 8. The FM signal is discriminated to recover the analog signal. Band-pass filters at 3 Hz and 100 Hz (48 dB per octave) were used to reject unwanted frequencies and to minimize aliasing effects on the sampled data. The data is calibrated at this point and converted to non-dimensional quantities. The T/D 100 Analyzer was used to compute the PSD's, cross-PSD's, and Probability Densities. The stochastic algorithms utilized by the T/D 100 to perform these functions are discussed below.

After each PSD or cross-PSD was plotted, the spectral coefficients were punched, in ASCII format, on perforated paper tape. This paper tape was then fed into an SEL-810A mini-computer for transcription to magnetic tape. This was done to increase storage density, for ease of handling, and for speed of subsequent playback.

Auto-Spectral Density (PSD)

The T/D 100 computes the PSD coefficients by first approximating the complex Fourier transform of the input signal. The

Fourier transform of the time-domain input function $x(t)$ is given by:

$$G(jf) = \int_{-T/2}^{T/2} x(t) (\cos 2\pi ft - j \sin 2\pi ft) dt \quad (1)$$

where $j = \sqrt{-1}$. Since the time-domain input is sampled and quantitized in the analyzer, and only a finite number of samples are available, the finite transform is used, and, separated into its real $P(f)$ and imaginary $Q(f)$ components, can be written as follows:

$$P_T(f) = \int_{-T/2}^{T/2} x(t) \cos 2\pi ft dt \quad (2)$$

$$Q(f) = \int_{-T/2}^{T/2} x(t) \sin 2\pi ft dt \quad (3)$$

where T is the length of the input frame, which is assumed to be centered about time $t=0$.

Replacing the continuous input, $x(t)$, with a set of $2N+1$ discrete samples at intervals of $t_0 = \frac{1}{2N}$, and replacing the sinusoidal functions by corresponding values, the continuous integrals may be expressed as the sum of products:

ORIGINAL PAGE
OF POOR QUALITY

ORIGINAL PAGE IS
OF POOR QUALITY

$$P(kf_0) = \sum_{n=-N}^{+N} x(nt_0) \cos \left[2 kf_0(nt_0) \right] \quad (4)$$

$$Q(kf_0) = \sum_{n=-N}^{+N} x(nt_0) \sin \left[2 kf_0(nt_0) \right] \quad (5)$$

where k is a series of $2N$ integers and f_0 is the base frequency which is equal to $\frac{1}{2T}$.

The PSD coefficients $[S(kf_0)]$ are then computed from (4) and (5) by the equation:

$$S(kf_0) = \left| P(kf_0) \right|^2 + \left| Q(kf_0) \right|^2 \quad (6)$$

Cross-Spectral Density (XPSD)

The T/D 100 computes the XPSD (S_{AB}) by simultaneously computing the complex Fourier transform of channel A ($P_A + jQ_A$) and channel B ($P_B + jQ_B$) and multiplying the channel A transform by the complex conjugate of the channel B transform as follows:

$$\begin{aligned} S_{AB} &= (P_A + jQ_A) (P_B - jQ_B) \\ &= P_A P_B + Q_A Q_B + j(P_B Q_A - P_A Q_B) \end{aligned} \quad (7)$$

The spectrum is then separated into its real ($S_{P,AB}$) and imaginary ($S_{Q,AB}$) components as follows:

$$\begin{aligned} S_{P,AB} &= P_A P_B + Q_A Q_B \\ S_{Q,AB} &= P_B Q_A - P_A Q_B \end{aligned} \quad (8)$$

The T/D 100 then puts the real component into the channel A output buffer and the imaginary component into the channel B output buffer.

Probability Density

On the T/D 100 the Probability Density of a time-domain input is ascertained by performing an Amplitude Histogram on the input function. This algorithm counts the number of times that each of 255 discrete amplitudes occurs at the input. Zero-amplitude occurrences appear mid-scale of the output display with negative-amplitude occurrences increasing to the left of mid-scale and positive-amplitude occurrences increasing to the right.

Average rms (ψ_T)

The average rms of the input signal is calculated from the PSD coefficients $S(kf_0)$ by the following equation:

$$\psi_T = \sqrt{f_0 \sum_{k=0}^{2N} S(kf_0)} \quad (9)$$

where $f_0 = \frac{1}{2NT}$ is the base frequency or analysis bandwidth.

SECTION 7

PRESENTATION OF TABULATED DATA

During the course of the study, approximately 800 power spectra were obtained. These data have two primary uses. First they permit identification of the significant modal contributions through comparison with the ground vibration test data obtained in the F-111 development program. Second they provide the data base for future assessment of prediction methods.

Natural Vibration Modes

A summary of measured natural vibration modes of the F-111A at 26 degrees leading-edge sweep is presented in Table 8. Most of the values were taken from tests previously conducted on Airplane No. 12 which is structurally the same as Airplane No. 13 (Reference 18). A few of the measurements were taken on Airplane No. 1 and were not repeated on Airplane No. 12 because the parts and associated structure had not changed (Reference 19). Data are presented for two fuel loading conditions: fuselage empty, wing empty and fuselage full, wing empty. Note that the difference in fuselage fuel load affects some of the natural frequencies.

Table 9 presents calculated values of symmetric vibration mode frequencies obtained using a math model of the aircraft structure for two gross weight conditions which represent specific loadings occurring on maneuvers investigated in this study. These calcula-

ted mode frequencies serve the purpose of clarifying some measured responses which were not clearly identified in the ground vibration tests because of the close proximity of other modes.

Power Spectral Density Tabulated Data

In this Section all power spectral density data obtained during the Phase I investigation are presented in tabulated form for the convenience of those who might wish to perform analyses and/or comparisons other than those presented in NASA CR-152109 and NASA CR-152110.

The arrangement of the tabulated data is as follows.

Each set of PSD's correspond to a particular instrumentation item at a particular flight point identified in Table 7. The progression in the record number is continuous within a given maneuver. For example, if there are 6 points listed in Table 7 for a given maneuver then records 1-6 are for points 1-6 for the first instrumentation item, records 7-12 are for points 1-6 for the second instrumentation item, etc. The last record number listed for a particular maneuver gives the total number of PSD sets obtained for that maneuver.

The item code corresponds to the instrumentation code listed in Table 4. The second line of each data set identifies the particular point within the maneuvers listed in Table 7. The flight number identification is obvious. The frame number and

record length correspond to the start time, T_1 , and time interval, ΔT , listed in Table 7.

The data are scaled so that the tabulated values are integers. Each entry corresponds to a specific value of frequency from 1 to 100 Hz. The first row of data is for frequencies from 1 to 20 Hz from left to right, the second row for 21 to 40 Hz, etc. The scale factors are labeled:

$$\text{PSD value of 1.0} = 0.\text{XXXX E } \frac{1}{2} \text{ YY}$$

where the numerical value is in floating point format and corresponds to U.S. Customary Units for the particular item of instrumentation. This value represents the dynamic threshold for the analysis equipment for the particular set of data. An entry of 0 in the tabulated data means that the measurement for that frequency was below the dynamic threshold of the equipment.

Although data are presented for frequencies from 1 to 100 Hz in each record, the frequency limits for the particular items of instrumentation and flights listed in Table 5 should be observed when working with the tabulated or plotted data.
