Langley Research Center
Hampton, Virginia 23665

The cruise parameter (product of Mach number and lift to drag ratio) was a maximum close to airfoil design point. The configuration was found to be positively stable with normal control effectiveness about all three axes in the lift coefficient and Mach number range of interest.

INTRODUCTION

The span-distributed load (Spanloader) concept recently has received considerable attention as a promising approach towards future large, all-cargo aircraft (refs. 1 - 4). In this concept, the payload is contained within a thick wing and uniformly distributed spanwise to largely balance the lift distribution and thus reduce bending stresses. The resulting improvement in structural efficiency allows higher payload fraction than possible with conventional wing-fuselage designs. Additionally, the use of an untapered, untwisted wing having uniform section enhances the commonality of parts and results in economical manufacture.

Crucial to the success of this approach are efficient, supercritical type airfoils of thickness ratio in the order of 0.2. Little research background or design experience exists in this area; also, the high-lift capability, stability, control and Mach number effects on the performance of tail-less thick wing configurations are relatively unknown.

Wind tunnel tests were carried out on a representative spanloader model in order to acquire a preliminary data base and to uncover any aerodynamic peculiarities of such configurations needing further study. Six-component balance measurements were performed at subsonic Mach numbers up to the buffet limit. Wing-pod filleting, airfoil modification, pod/wing interaction, trailing-edge deflection, tip-fin effectiveness and lateral-directional stability and control were also explored. This report presents the basic wind-tunnel data and briefly discusses the principal results.

SYMBOLS

The data are referred to the stability-axis system with the moments referenced to the point shown in Fig. 1A. The symbols are defined as follows:

- b wing span (1.452 m)
- C_D drag coefficient, Drag/ $q.S$
- C_L lift coefficient, Lift/ $q.S$
- C_{l_1} rolling-moment coefficient, Rolling moment/ $q.S.b$
- $C_{l_{1\beta}}$ rolling-moment due to sideslip, $\partial C_{l_1}/\partial\beta$ per degree
- C_m pitching-moment coefficient, Pitching moment/ $q.S.c$
- C_n yawing-moment coefficient, Yawing moment/ $q.S.b$
- $C_{n\beta}$ yawing-moment due to sideslip, $\partial C_n/\partial\beta$ per degree
- C_Y side-force coefficient, Side force/ $q.S$
- $C_{Y\beta}$ side force due to sideslip, $\partial C_Y/\partial\beta$ per degree
- c chord (6.58 cm)
- q free stream dynamic pressure
- S reference area of wing (0.191 m²)
- L/D lift-to-drag ratio
- M free-stream Mach number
- R_c Reynolds number based on chord
- α angle of attack, degrees
- β angle of sideslip, degrees
- δ deflection (of flap, elevon, vertical tail), degrees

Subscripts

- A aileron
- EI elevon, inboard

ET elevon, tip
F1 flap, inboard
F2 flap, outboard
VT vertical tail

DESCRIPTION OF MODEL

The model (Fig. 1A) represented on a 1/100 scale a conceptual tail-less configuration with 30° swept-back, untwisted, constant-chord wing. In addition to the center-body (sized to accommodate the balance) the wing carried two axi-symmetric pods (length to diameter ratio 8). The outboard pods close to the wing tips carried the vertical tails. Three different pairs of vertical tail were available (Fig. 1B). The entire trailing edge of the wing was occupied by flaps and elevons of 20 percent chord. The propulsion system was represented by a total of eight engine nacelles (through-flow type) mounted over the wing on swept-forward pylons.

The 20 percent thick (streamwise) cambered airfoil (Fig. 1C) was designed for a small positive zero-lift moment and also to be free of separation or wave drag at $M = 0.6$, $C_L = 0.4$, $R_c = 90 \times 10^6$ in two-dimensional flow (see page 18 for airfoil co-ordinates). The low-moment requirement distinguished the present airfoil from the well-known Whitcomb aft-loaded profiles which have a relatively high negative zero-lift moment and therefore not suited for use on tailless aircraft. It was also anticipated that the Spanloader would utilize active control technology; accordingly, the present design aimed for neutral stability about the center-of-gravity located 30.35 cm aft of the center-body nose, which is the aerodynamic center as calculated by vortex-lattice theory (ref. 6).

APPARATUS, TESTS AND CORRECTIONS

This investigation was carried out in the Langley 7- by 10-foot slotted-wall high speed wind tunnel with atmospheric stagnation

pressure. Forces and moments were measured by an internally mounted, six-component strain-gage balance.

Tests were done over a Mach no. range of 0.3 to 0.725 which corresponds to a Reynolds no. range of 1.1×10^6 to 2.04×10^6 based on wing chord. The angle of attack was varied from -2° to a maximum of $+18^\circ$, at sideslip angles of 0° and $\pm 4^\circ$. The angles of attack and sideslip have been corrected for balance and sting bending due to aerodynamic loads. The axial force measurement of the balance was adjusted to a condition of free-stream static pressure acting on the base of the model. Transition strips*0.82 cm in width of # 100 carborundum grains were placed at 1.52 cm streamwise aft of the leading edge of wing and vertical tails, and also at an axial distance of 3.05 cm from the nose of the center-body and pods.

A photograph of the complete model configuration mounted in the tunnel test-section is shown in Fig. 2.

PRESENTATION OF RESULTS

The basic longitudinal characteristics are graphically presented in Figs. 3 through 19, followed by lateral-directional characteristics in Figs. 20 through 27. The tabulated data will be found following page 25. Analysis plots prepared from these basic data to illustrate principal features of the results (included in Discussion) are presented in Figures 28 through 41.

*See reference 7.

DISCUSSION OF RESULTS

Filleting

The wing-body and wing-pod junctions on the original model were not provided with fillets. The drag-reduction potential of fairing these junctions was briefly investigated. Body-putty was used to form the fillets to an arbitrary but reasonably smooth shape; no record of the fillet geometry is available.

As seen from the L/D data in Fig. 3 the result of the first trial (labelled "large" fillets) was negative. A second attempt with reduced-size fillets (labelled "small") however produced an 8 percent gain in $(L/D)_{\max}$ at $M = 0.3$ (somewhat less at $M = 0.5$). The drag increment due to the two types of fillets is compared in Fig. 28. Note that the effectiveness of the "small" fillets is lift-dependent reaching a maximum at about $C_L = 0.4$, whereas the drag improvement at zero-lift is relatively small. Although the data are limited and probably Reynolds no. sensitive, they are illustrative of the drag-reduction potential of optimum fillets. A rational procedure for fillet design aimed at the cruise condition may significantly contribute towards the aerodynamic efficiency of multi-podded configurations.

Airfoil Modification

An oil-flow test at $\alpha = 2^\circ$ revealed a spanwise outflow on the wing upper surface over the rear 25 percent chord (Fig. 29A). This type of surface flow pattern on swept-back wings is well-known to be associated

with three-dimensional boundary layer separation. In an attempt to eliminate this low angle-of-attack separation a simple modification of the airfoil was tried: the concave portion on the upper surface was filled in to the trailing edge producing a flat tangent surface (see Fig. 1C). Subsequent oil-flow visualization showed a greatly reduced outflow (Fig. 29B), implying that this modification had successfully alleviated separation. As a consequence, a 15-count reduction in zero-lift drag and a 10 percent increase in $(L/D)_{\max}$ were obtained (Figs. 5, 6).

A brief computational study using a two-dimensional airfoil analysis method (Korn-Garabedian including boundary layer) was performed to check the above experimental finding, and also to assess the profile modification at design condition and at full-scale Reynolds number. The calculated results are presented in the following Table:

M	C_L	$R_c = 1.6 \times 10^6$				$R_c = 90 \times 10^6$				
		Original		Modified		Original		Modified		
		C_D	$C_{m,c/4}$	C_D	$C_{m,c/4}$	C_D	$C_{m,c/4}$	C_D	$C_{m,c/4}$	
0.3	0	.0153	.0228	.0125	.0099	.0064	.0028	.0055	-.0147	
		[0.76]		[0.915]		[1.0]		[1.0]		
	0.4	.0157	.0162	.0139	.0113	.0064	.0063	.0059	-.004	
		[0.72]		[0.85]		[1.0]		[1.0]

		[0.72]		[0.915]		[1.0]		[1.0]		
	0.4	.0128	.0237	.0122	.0128	.0064	.0086	.0064	-.0046	} Design case
		[0.70]		[0.86]		[1.0]		[1.0]		

Note: [] denotes distance to upper surface separation point as a fraction of chord length.

Calculations at $R_c = 1.6 \times 10^6$ (the test Reynolds no.) predicted upper-surface separation close to the experimental position on the original airfoil, and also its observed movement towards the trailing edge on the altered profile. A corresponding drag reduction was also obtained in the calculation, although it should be noted that drag computation in presence of separation is questionable (see for example ref. 5). According to calculation at full-scale Reynolds no. (90×10^6), the original profile already was separation-free and yet the modification yielded significant drag reduction in all cases (with the sole exception of the design point, where the drag was unchanged). This improvement however was accompanied by a nose-down pitching moment, to be expected from a partial removal of the negative aft-end camber by the profile modification. In an attempt to counter this adverse effect the under-surface concavity also was filled in, and the resulting profile analyzed at the design point. This indicated a C_m improvement (Fig. 30) with no change in C_D . Subject to experimental validation, these calculations indicate some scope for simplification of the present airfoil geometry without materially affecting its cruise-point performance.

At the conclusion of the airfoil-modification tests, the fill-in was removed and the wing returned to its original section; all other results discussed in this report pertain to the unmodified airfoil.

Configuration Build-Up

Starting with the plain wing plus center-body, successive additions of pods, vertical tails and engine nacelles were tested. The most noteworthy change observed was that due to the addition of pods. As

seen in Fig. 31, a pod effect distinctly appears at about $\alpha = 7^\circ$ to the benefit of lift-curve slope, lift-dependent drag and, more significantly, pitch stability. The pitch-up typical of swept wings is reversed into a nose down moment. The pods presumably control wing flow separation particularly near the tips, possibly through forebody lee-side vortices which come into effect at a particular angle of attack. A more detailed study of the pod effect appears worth while with a view to its exploitation in tail-less configuration designs.

Vertical Tail Toe-In

The three vertical-tail designs (Fig. 1B) were tested at toe-in angles of 1° , 3° and 5° to observe the effect on configuration $(L/D)_{\max}$. The results are shown in Fig. 32 and compared with tail-off $(L/D)_{\max}$.

The vertical tails with symmetrical section (VT1 and VT2) show the most effect of toe-in; the optimum toe-in angle appears to be about 1.5 degrees. The vertical tail (VT3) having a cambered blunt leading-edge airfoil is relatively insensitive to toe-in, as might be expected. The $(L/D)_{\max}$ of the configuration is about the same with all three vertical-tail designs, notwithstanding the 75% larger area of VT2 compared with the other tails.

Trailing Edge Controls

Lift and pitching-moment increments due to trailing-edge controls deflected in various combinations of flaps and elevons are presented in Fig. 33. These data indicate a trim point with 30° flaps and all elevons at -15° deflection. The trimmed lift coefficient at 30° flaps

is plotted against angle of attack in Fig. 34. The usable C_L with this flap deflection falls considerably short of required $C_L = 1.0$ estimated for zero-rotation take off and approach at 3° glide-slope (assuming 130 knots speed and 55 p.s.f. wing loading). From the trends of ΔC_L and ΔC_m with flap deflection at $\delta_F = 30^\circ$, an increase in trimmed C_L of about 0.1 appears probable with 40° flaps. Note that these indications are based on data without ground effect (an important consideration on the Spanloader) or Reynolds number influence. Both these effects need investigation for a more realistic assessment of the high-lift capability of the configuration.

A feature of the trailing-edge deflection data is the indicated $(L/D)_{\max}$ gain over the zero-deflection case, noted in several instances (see Figs. 12 to 16). This effect is presumably related to favorable changes in spanwise lift distribution produced by certain combinations of flaps and elevon deflection, where the resulting decrease in induced-drag exceeds the profile-drag increment. Within the scope of the available data however, such favorable instances do not coincide with a trimmed condition. The effect nevertheless appears worth studying in greater detail with a larger number of trailing-edge segments and smaller deflections, and including the cruise Mach number.

Mach Number Effects

The variation of drag coefficient with Mach number at various lift coefficients is shown in Fig. 35. The drag-rise Mach number (at $dC_D/dM = 0.1$) is indicated on each $C_L = \text{const.}$ curve.

The maximum L/D as a function of Mach number is shown in Fig. 36. Applying the usual Reynolds number extrapolation to the skin-friction drag indicates that these $(L/D)_{\max}$ values will be roughly doubled at full scale ($R_c = 90 \times 10^6$). The C_L at $(L/D)_{\max}$ varies but little from 0.4 over the Mach number range. The maximum in cruise-efficiency parameter $M.L/D$, also shown in Fig. 36, occurs surprisingly close to the airfoil design point in spite of the large difference between the test and the design Reynolds numbers.

A Mach number effect on the longitudinal stability is discernable in Fig. 19. A distinct pitch-up is first observed in $M = 0.5$ data, and with further increase in Mach number the pitch-up onset occurs progressively earlier in C_L and also grows in severity.

A systematic rolling-moment variation with angle of attack was noted in the zero-yaw tests (Fig. 20). The rolling moment probably arises from a minor roll misalignment in the model mounting, such that one wing panel is effectively at a slightly higher angle of attack than the other. This ultimately leads to asymmetric stall and a sudden reversal in the rolling moment, providing a convenient means for identifying the onset of flow separation from balance data.

A summary of Mach number effects is presented in Fig. 37. The boundaries in this C_L versus Mach number plot are based on various limiting features deduced from balance data. At Mach numbers up to 0.5 the usable (untrimmed) lift coefficient is considered to be limited by low-speed stall onset as indicated by the rolling-moment break. For

$M > 0.5$, pitch-up instability limits the usable C_L (pitch-up at lower Mach numbers presumably occurs beyond the C_L range of the data). The drag rise Mach number boundary represents the cruise performance limit.

The location of target cruise point relative to constant M.L/D contours in Fig. 37 suggests that some increase in Mach number may perhaps be permissible without loss in cruise performance.

Lateral/Directional Stability

The lateral stability parameter $C_{l_{\beta}}$ obtained from tests at ± 4 degrees sideslip is plotted versus C_L in Fig. 38 for Mach numbers 0.3 and 0.6. The effects of successively adding nacelles and vertical tails (VT3) to the podded wing are shown here. The changes in lateral stability characteristics produced by the addition of nacelles (and their support pylons) are relatively large and complex, and also quite different at the two Mach numbers. It may reasonably be expected that these changes are related to interference of forward-mounted pylons with the wing flow. Addition of vertical tails has a small favorable effect. The complete configuration is found to possess lateral stability throughout.

The directional stability parameter $C_{n_{\beta}}$ is plotted versus C_L at the two Mach numbers in Fig. 39. The destabilizing effect of adding nacelles to the podded wing is noted. The further addition of vertical tails (VT3) restores directional stability to the configuration.

Lateral/Directional Control

A number of aileron-deflection combinations (sketched on top of Fig. 40) were tested at $M = 0.3$. The test cases included: tip ailerons

only, inboard ailerons only, both tip and inboard ailerons, right and left ailerons deflected in opposition as well as differentially together. The average rolling-moment increment for all the nine cases show a good correlation with the effective aileron deflection angle δA (as defined in the figure) giving $\delta C_{l_1}/\delta A = .0005$ per degree up to $\delta A = 40^\circ$. The ailerons remain fully effective up to the maximum lift coefficient (see Fig. 26).

The directional control due to all-moving vertical tails is shown in Fig. 41. The 75% larger area of VT2 produces a proportionately greater rudder power than VT1. Between vertical tails of identical planform and area, the one with cambered airfoil (VT3) generates about 38% higher control power. All three vertical tails produce essentially constant control effectiveness with lift coefficient at $M = 0.3$.

CONCLUSIONS

1. Proper filleting of the wing-body and wing-pod junctions significantly improved the configuration $(L/D)_{\max}$.
2. Flattening of the concave upper-rear part of the airfoil largely controlled the flow separation observed in that region at small angles of attack and produced $(L/D)_{\max}$ increment. Two-dimensional airfoil analysis indicated that the observed separation was a low Reynolds number effect. At full-scale Reynolds number (with no separation on the original airfoil) the predicted effect of this modification is to produce an undesirable nose-down moment; however, by flattening the concavity in the rear lower surface also, the theoretical drag and pitching-moment characteristics of the original airfoil at design-point are recovered.

3. Addition of pods improved the longitudinal characteristics of the plain wing above 8° angle of attack, and in particular eliminated the pitch-up instability.
4. Wing-tip vertical tails of cambered airfoil section required no toe-in for best $(L/D)_{\max}$ of the configuration and also had better directional control effectiveness than tails of symmetrical section.
5. With 30° flap deflection (maximum tested) the trimmed lift coefficient (in absence of ground effect) was considerably short of the estimated requirement for zero-rotation take off.
6. The cruise parameter $M.L/D$ reached a maximum close to the airfoil design point ($C_{L_i} = 0.4$; $M = 0.6$) with adequate margins before pitch-up and drag rise.
7. The configuration exhibited positive lateral and directional stability with normal roll and yaw control effectiveness in the Mach number and C_L range of interest.

16. Abstract A basic wind tunnel study was conducted on a 1/100-scale model of a tail-less, span-distributed advanced cargo aircraft (Spanloader) concept. The configuration consisted of a 30° -swept, untapered, untwisted wing utilizing a low-moment cambered airfoil of 20 percent streamwise thickness designed for low wave drag at $M = 0.6$, $C_L = 0.4$. The tests covered a range of Mach numbers 0.3 to 0.725 and chord Reynolds no. 1.1×10^6 to 2.04×10^6 , angles of attack up to model buffet and sideslip angles $+4^\circ$. Configuration build-up, wing-pod filleting, airfoil modification and trailing-edge control deflection effects were briefly investigated. Three wing-tip vertical tail designs were also tested. Wing-body filleting and a simple airfoil modification both produced increments to maximum lift/drag ratio. Addition of pods eliminated pitch instability of the basic wing. While the magnitude of these benefits probably was Reynolds no. sensitive, they underline the potential for improving the aerodynamics of the present configuration. The cruise parameter (product of Mach number and lift/drag ratio) attained a maximum close to the airfoil design point. The configuration was found to be positively stable with normal control effectiveness about all three axes in the Mach no. and C_L range of interest.
