The Laboratory Operations of The Aerospace Corporation is conducting experimental and theoretical investigations necessary for the evaluation and application of scientific advances to new military concepts and systems. Versatility and flexibility have been developed to a high degree by the laboratory personnel in dealing with the many problems encountered in the nation's rapidly developing space and missile systems. Expertise in the latest scientific developments is vital to the accomplishment of tasks related to these problems. The laboratories that contribute to this research are:

Aerophysics Laboratory: Launch and reentry aerodynamics, heat transfer, reentry physics, chemical kinetics, structural mechanics, flight dynamics, atmospheric pollution, and high-power gas lasers.

Chemistry and Physics Laboratory: Atmospheric reactions and atmospheric optics, chemical reactions in polluted atmospheres, chemical reactions of excited species in rocket plumes, chemical thermodynamics, plasma and laser-induced reactions, laser chemistry, propulsion chemistry, space vacuum and radiation effects on materials, lubrication and surface phenomena, photosensitive materials and sensors, high precision laser ranging, and the application of physics and chemistry to problems of law enforcement and biomedicine.

Electronics Research Laboratory: Electromagnetic theory, devices, and propagation phenomena, including plasma electromagnetics; quantum electronics, lasers, and electro-optics; communication sciences, applied electronics, semiconducting, superconducting, and crystal device physics, optical and acoustical imaging; atmospheric pollution; millimeter wave and far-infrared technology.

Materials Sciences Laboratory: Development of new materials; metal matrix composites and new forms of carbon; test and evaluation of graphite and ceramics in reentry; spacecraft materials and electronic components in nuclear weapons environment; application of fracture mechanics to stress corrosion and fatigue-induced fractures in structural metals.

Space Sciences Laboratory: Atmospheric and ionospheric physics, radiation from the atmosphere, density and composition of the atmosphere, aurorae and airglow; magnetospheric physics, cosmic rays, generation and propagation of plasma waves in the magnetosphere; solar physics, studies of solar magnetic fields; space astronomy, x-ray astronomy; the effects of nuclear explosions, magnetic storms, and solar activity on the earth's atmosphere, ionosphere, and magnetosphere; the effects of optical, electromagnetic, and particulate radiations in space on space systems.

ABSTRACT

This report is the user's guide to the data obtained by the ATS-6 Aerospace Corporation energetic particle detector and deposited at the National Space Science Data Center. Contained are descriptions of the instrument, calibration data, information on instrumental and operational anomalies and a description of the procedures used to reduce the data. A description of the format of the data is also presented.

Abstract

The Aerospace Corporation energetic electron proton spectrometer operating on Applications Technology Satellite-6 (ATS-6) detects energetic electrons in four channels between 140 keV and greater than 3.9 MeV, and measures energetic protons in five energy channels between 2.3 and 80 MeV and energetic alpha particles in three channels between 9.4 and 94 MeV. After more than a year of operation in orbit, the experiment continues to return excellent data on the behavior of energetic magnetospheric electrons as well as information regarding the fluxes of solar protons and alpha particles.

I. Introduction

The region of space near the synchronous altitude is a fascinating part of space where various domains of the magnetosphere meet and interact. Fig. 1, taken from Frank [1], graphically illustrates the confluence of the plasma-pause, the extraterrestrial ring current, the boundary of the zone of energetic particles, and the Earthward terminus of the plasma sheet in the immediate vicinity of $6.6 R_e$. The study of the interaction of the various plasmas with vastly different densities and temperatures and the energization and dynamics of these plasmas are the goals of the Environmental Measurements Experiments (EME) on Applications Technology Satellite-6 (ATS-6).

The aerospace experiment described in this paper contributes to these goals through measurements of the high energy tail of the electron distribution function. The experiment covers the energy range for electrons from 140 keV to greater than 3.9 MeV, and the experiment is expected to yield important results regarding the acceleration and dynamics of the energetic electrons. While previous measurements (see the compilations [8] and [9]) have contributed a great deal of information regarding the behavior of energetic electrons at the synchronous altitude, comprehensive measurements such as those being made on ATS-6 of the entire distribution function for a given particle species have never been made.

Not shown in Fig. 1, but also present in this region of space during solar particle events, are energetic protons and alpha particles (and possibly electrons) of solar origin. These solar particles may penetrate to altitudes as low as $4 R_e$ (depending on particle rigidity and magnetic activity) but, in general, the gradient of solar protons is located somewhere in the vicinity of $6.6 R_e$. The experiment measures the fluxes and spectra of solar particles reaching the synchronous orbit. (The proton thresholds of this experiment are too high to permit the detection of the proton component of the trapped radiation.)

II. Description of the Experiment

A. Physical and Electronic Configuration

The instrument consists of four separate sensors, one two-detector element telescope and three omnidirectional single-detector units. An overall view of the instrument is presented in Fig. 2, and a functional schematic of the electronics is presented in Fig. 3.

The counter telescope uses silicon surface-barrier detectors of ORTEC manufacture behind a disk-loaded collimator. The first detector is 50 mm^2 in area and $230 \mu\text{m}$ deep and the second detector is 200 mm^2 in area and $100 \mu\text{m}$ deep. Both are totally depleted. Five electronic discriminator levels are used with the first detector. The two upper levels are set above the maximum energy a proton can deposit in the detector and thus are sensitive to alphas only (actually $Z \geq 2$). The next two levels are sensitive to protons (actually all ions) but not electrons, and the lowest

Fig 1 Spatial relationships near the synchronous orbit at local midnight between the ring current, the plasmopause, the energetic particle trapping boundary, and the Earthward terminus of the plasma sheet. This figure is qualitative and representative of magnetic quiet (from Frank [1])

Fig 2 Overall view of the energetic particle spectrometer on ATS-6. Directional detectors are housed inside the cylindrical collimator structure in the foreground.

level is sensitive to all particles in the appropriate energy range. The sole function of the second detector is to inhibit from analysis any penetrating particles. Section IIB provides details about the energy channels.

The three omnidirectional sensors use small cubical lithium-drifted silicon detectors centered under a hemispherical shell and heavily shielded (relative to the hemispherical shield) over the rear 2π solid angle. Protons are separated unambiguously from electrons by setting the second discriminator level well above the maximum energy an electron can deposit in the small semiconductor detector. The fact that dE/dx (energy loss per unit path length) is much greater for protons than for electrons (in the energy range of geophysical interest) is utilized. The absence of electron contamination in the proton channels was verified by electron irradiation of the sensors. The proton threshold of each of the three sensors was determined primarily by the thickness of the hemispherical shield, with the energy threshold of the two most lightly shielded units somewhat affected by the electronic thresholds as well. The most lightly shielded omnidirectional sensor has a third electronic level set above the maximum proton energy deposit to provide an alpha particle channel. The two heavier hemispherical shields were made of beryllium to minimize Bremsstrahlung and maximize the threshold sharpness. The most lightly shielded shield is aluminum since an aluminum shield is much cheaper and the performance difference negligible for such a thin shield.

The electronic subsystem of the experiment is shown schematically in Fig 3. The input stage of the preamps utilize an n-channel field-effect transistor. In order to maintain a low system noise, the input stage is enclosed in a shielded compartment. The characteristic long-tail pulse from the preamplifier is shaped by a pole-zero shaping network into a pulse with a $1\text{-}\mu\text{s}$ time constant. The high level discriminators (greater than 8 MeV) are driven directly from the output of the shaping circuit. Output from the shaping network is also coupled to an operational amplifier which provides the additional gain required to trigger the

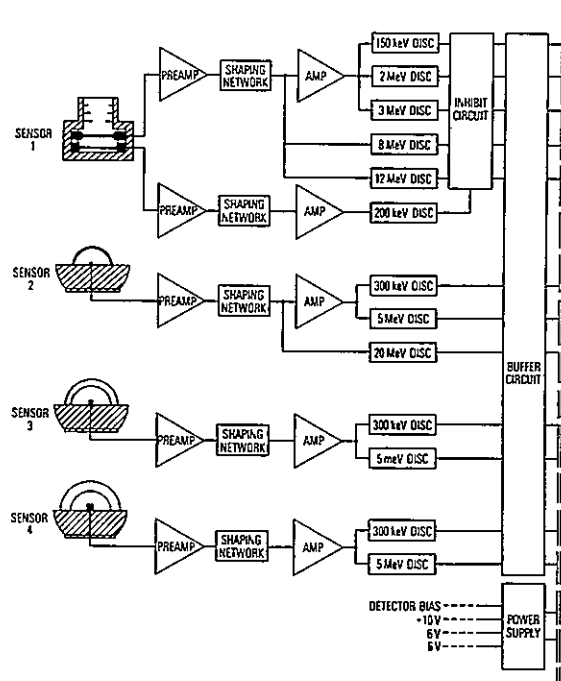

Fig 3 Schematic block diagram of detector/electronic system

low energy thresholds. Preamplifier gain is set by an adjustable feedback capacitor. Gain of the operation amplifier is set by a feedback resistor.

The discriminator is essentially a comparator driving a tunnel diode. The threshold voltage is set by a lab-set resistor. Output from the discriminator is a 0-5-V pulse with an approximate duration of a microsecond. A COS/MOS buffer circuit accepts the 0-5-V discriminator pulse and provides a 0-10-V pulse to interface with the spacecraft encoder.

Sensor 1 uses two sets of circuits identical to those used for sensors 2, 3, and 4. The front detector of the two-detector array has five discriminators which drive an inhibit circuit, particles penetrating through the first detector are

Fig 4 Efficiency of detection of electrons in the E1 channel This channel has a nominal energy sensitivity of 140-600 keV Sensitivity of this channel below the nominal electronic threshold is associated with the finite noise of the detector

Fig 5 Effective area of the E2, E3, and E4 electron channels as a function of electron energy This effective area, when integrated over the angular response of the detector, yields the omnidirectional geometric factor

Fig 6 Efficiency for detection of protons in the P1 and P2 channels of the counter telescope

Table I

Channel	Passband or Threshold (MeV)	ϵG
E1	0.140 - 0.600	$115 \text{ cm}^2 \cdot \text{sr}$
E2	0.700	0.0349 cm^2
E3	1.55	0.176 cm^2
E4	3.90	0.688 cm^2

thus rejected COS/MOS logic is used to perform the trailing edge logic in the inhibit circuit Trailing edge logic is used to compensate for "walk" in the discriminators Outputs from the inhibit circuit are also buffered to interface with the encoder

A DC-DC converter provides the required instrument bias voltages Power from the spacecraft is coupled to a series pass stage to limit the experiment turn on transient and to protect spacecraft relays The converter section is completely enclosed in an electrostatic shield to minimize undesirable pickup by the counting circuits Total power consumption is 475-540 mW, depending on the count rate at which the instrument is operating

Terminal boards with discrete components and point-to-point wiring are used in the construction of the amplifiers, discriminators, and power supply Printed circuit and integrated circuits are used for the inhibit and buffer circuits Total experiment weight is 1.2 kg

B. Detector Calibration Data

1) *Electron Channels* Figs 4 and 5 display the electron calibration data in graphical form The E1 channel employs a directional geometry of $1.6 \times 10^{-1} \text{ cm}^2 \cdot \text{sr}$, the E2, E3, and E4 channels used on omnidirectional geometry and thus the calibration data, obtained with a plane parallel beam, must be integrated over the angular acceptance of these detectors in order to arrive at the omnidirectional efficiency as a function of energy However, it is convenient to define thresholds and geometric factors for obtaining rapid estimates of fluxes These thresholds and geometric factors are calculated by numerically integrating the response function over various spectral shapes and finding the threshold which minimizes the variation of the calculated geometric with spectral shape The results are given in Table I

The proton and alpha particle channels have negligible sensitivity to electrons.

2) *Proton Channels* The proton calibration data for channels P1 and P2 are shown in Fig. 6 The thresholds of these two channels are sharp enough $[\Delta E/E_{\text{threshold}} \ll 1]$, where $\Delta E \sim E (\epsilon = 90 \text{ percent}) - E (\epsilon = 10 \text{ percent})$ to eliminate the need for numerically integrating over the response function The geometric factors of the other proton channels (the omnidirectional sensors) were computed and spot checked at several energies where accelera-

tor protons were available. Table II gives the results. Unfortunately, ATS-6 weight constraints prevented the use of sufficient back shielding to render back penetration negligible for all proton spectra. Two different thicknesses of shielding covered the rear hemisphere and thus each channel has three passbands and geometric-factors. These "rear passbands" are also given in Table II.

In all cases the electron channels are sensitive to protons. However, as a general rule, at the synchronous orbit the electron fluxes far exceed those of the trapped protons. Under unusual conditions, i.e., during solar proton events apparent electron counts can be due to protons. The efficiencies of the electron channels for protons are given in Table III.

The proton channels can be triggered by alphas (or higher Z particles), the relative abundance of alphas to protons renders this contamination negligible.

III Operational History

The experiment on ATS-6 was first powered in orbit on June 14, 1974, and has been operating almost continuously since that time, such brief shutdowns of the experiment as have occurred have been associated with tests of other experiments on ATS-6. Several minor anomalies in the performance of the experiment have been observed during the first year of operation. None of these affect the quality of utility of the data in any significant way and all goals of the experiment are being met.

IV Preliminary Results

This brief summary of the preliminary results already obtained from the ATS-6 experiment is an indication of some of the unique contributions ATS-6 data will make to our understanding of the behavior of the magnetosphere and the entry and motion of solar particles in the magnetosphere.

A Energetic Electrons

The first data on energetic electrons obtained by ATS-6 showed that the electron fluxes were much more dynamic than earlier observations [5]-[7] on ATS-1 had indicated. ATS-6 data indicated the virtual disappearance of energetic electrons during portions of the orbit in the nighttime quadrant. Such "dropouts" were observed only rarely on ATS-1. In order to make a quantitative check on this impression, data were obtained from the experiment from ATS-1 for the same time period for a direct comparison of ATS-6 and ATS-1 energetic electron observations. These comparisons are shown in Figs 7 and 8. Fig 7 illustrates observations made during a magnetically quiet period (day 201) which was preceded by three days of magnetic quiet. In general, ATS-6 and ATS-1 energetic electron count rates

*The E1 electron channel is sensitive to protons with energies greater than 710 keV. The upper limit of sensitivity is of the order 190 MeV without the veto trigger, about 5.3 MeV when the particle enters, in such a way as to hit the veto detector.

show similar behavior. The sharp decreases in flux near 0430 UT and 0630 UT visible in the ATS-6 data are the results of substorms. Note that the effects of substorms on the energetic electrons are much attenuated at ATS-1 as compared with ATS-6.

During geomagnetically active periods, there is a substantial difference in the count rates observed by the two spacecraft. Fig 8 illustrates a comparison of observations made at ATS-6 and ATS-1 during a disturbed period. Note the total disappearance of flux at ATS-6 while ATS-1 always observes finite fluxes.

Fig 7 Comparison of energetic electron count rates observed by ATS-6 and ATS-1 during a magnetically quiet day (day 201). The three days preceding day 201 were also quiet.

The differences in phenomenology appear to be due to the different magnetic latitudes of the spacecraft. ATS-6 is located at about 10° magnetic latitude at its location of 94° W longitude, while ATS-1 is almost exactly on the magnetic equator at 150° W. The approximately 10° difference in magnetic latitude appears to be sufficient to place ATS-6, at times, into regions of space devoid of energetic electrons. Substorms, for example, as illustrated in Fig 7, have a greater effect on the energetic particle population off the magnetic equator. We can postulate that, during the later stages of a substorm, the geomagnetic field relaxes to more dipole-like configuration and the boundary of energetic particle trapping moves inward and equatorward past the ATS-6 spacecraft.

The comparisons of with ATS-1 ATS-6, data while still preliminary, indicate a surprisingly steep gradient in the energetic electron population as one moves away from the equator, in other words, a disk-like region of trapping of energetic electrons near $6.6 R_e$.

B The Solar Proton Event of July 4, 5, 6, 1974

Several solar proton events have been observed by the ATS-6 detectors during the first year of operation. Although the present time is a relatively quiescent part of the cycle of solar activity, modest outburst of protons (and heavy nuclei) were emitted by the sun during July and September 1974 and detected by this experiment and other experiments aboard ATS-6.

Solar protons of even relatively low energy are able to reach the synchronous altitude quite readily, without very much decrease in the flux as these particles transverse the outer regions of the geomagnetic field. This surprising result was first noted by experiments on ATS-1 [2], [4]. The ATS-6 experiments will provide very much better insight regarding the trajectories by which solar particles penetrate deeply into the magnetosphere, the gradients of solar particle fluxes near the synchronous orbits, and the effects of electromagnetic waves on the motion and lifetime of solar particles inside the geomagnetic cavity.

Fig 8 Comparison of energetic electron count rates observed by ATS-6 and ATS-1 during a magnetically disturbed day (day 205).

An overall view of July 1974 solar proton event, as observed by the experiment on ATS-6, is presented in Fig 9. The entire event is quite complex. The complexity arises partly because several emissions of particles by the Sun, somewhat separated in time, are superimposed and partly because disturbances in the geomagnetic field were also affecting the fluxes of solar particles.

The effect of one such disturbance, a compression of the geomagnetic field (presumably by an interplanetary shock) on solar protons moving within the geomagnetic field, is shown in Fig 10. The effect of such a compression is to increase the observed flux within a given energy channel because particles are accelerated. The acceleration process is identical to that which operates in betatrons. Furthermore, the changes in the configuration of the geomagnetic field cause the particle flux gradient to move past the detector. Study of the time development of flux changes, such as shown in Fig 10, can give information regarding the way particles interact with the spectrum at electromagnetic waves created during geomagnetic activity [3].

V Summary

After more than a year of operation in orbit, the experiment continues to provide excellent data. All design goals of the experiment have been met. While data analysis is still in the preliminary stages, it is clear that the experiment on ATS-6 will provide new and unique data regarding the behavior of energetic electrons at the synchronous altitude. In particular, correlation of ATS-6 data with data from other synchronous orbit spacecraft now operating (ATS-1, ATS-5) or planned for the future launches will give a much more complete view of the magnetospheric processes operating at high altitudes.

Acknowledgment

This experiment was the product of a large number of people whose efforts spanned many years, not because the

Fig 9 Count rates of proton and alpha channels during the solar proton event of July 1974 Data for two proton channels and two alpha channels for 4, 5, and 6 July 1974 are presented here

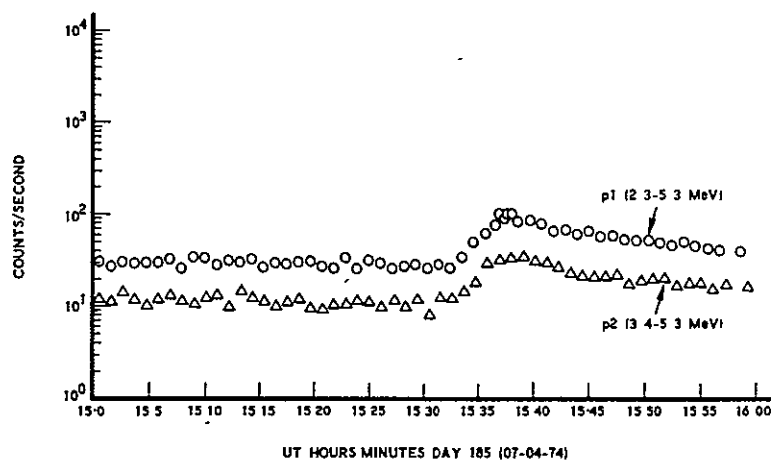

Fig 10 Increase in solar proton flux associated with a sudden commencement (a compression of the geomagnetic field) near 15 35 on July 4, 1974

experiment was particularly complex but because the launch of ATS-6 receded several times We are particularly grateful to Mrs G Roberts for the mechanical design of the experiment, to the Westinghouse group, particularly F McNally, J Ramsey, and W King, for their excellent support in the many test and checkout activities, and to R Wales of NASA Goddard Space Flight Center (GSFC) and his associates who saw the experiment through from beginning to end P McKowan of GSFC is providing excellent support in the data acquisition phase of this work Mrs. T Becker wrote the data analysis program which we have used to date

George A. Paulikas received the B.S. degree in engineering physics and the M.S. degree in physics from the University of Illinois, Urbana, in 1957 and 1958, respectively, and the Ph.D. degree in physics from the University of California, Berkeley, in 1961.

While at the University of California he was associated with the Lawrence Radiation Laboratory, doing research in plasma physics and atomic physics. In 1961 he joined the Space Physics Laboratory, The Aerospace Corporation, El Segundo, Calif., as a Member of the Technical Staff. In this capacity he conducted experimental space physics research, specializing in studies of trapped and quasitrapped radiation. He is now the Director of the Space Physics Laboratory. His fields of specialization include studies of the trapped radiation in the inner Van Allen Belt, measurements of the access of solar particles to the polar caps and to the synchronous orbit, construction of models of trapped radiation, and measurement of trapped alpha particles.

Dr. Paulikas is a member of the American Geophysical Union, the American Astronomical Society, the American Institute of Aeronautics and Astronautics, and Sigma Xi and is a Fellow of the American Physical Society. During 1957-1958 he was awarded a University of Illinois Fellowship, and from 1958-1961 he held a National Science Foundation Fellowship.

J. Bernard Blake received the B.S. degree in engineering physics in 1957, the M.S. degree in physics in 1958, and the Ph.D. degree in physics in 1962 from the University of Illinois, Urbana.

He was a Research Associate at the University of Illinois during 1962 when he joined the Space Physics Laboratory, The Aerospace Corporation, El Segundo, Calif., as a Member of the Technical Staff. He is presently Head of the Space Particles and Fields Department. His professional activity has included work in nuclear beta decay and parity nonconservation, the Mossbauer effect, studies of the geomagnetically trapped particles and auroral phenomena, cosmic ray sources, propagation and entry into the magnetosphere, and nuclear astrophysics. In applied work he has been concerned with nuclear weapons effects on ground and space systems, test monitoring, the interaction of the natural space environment with satellite systems, radiation damage effects, and the analysis of various satellite subsystems.

Dr. Blake is a member of the American Astronomical Society, the American Geophysical Union, the American Association for the Advancement of Science, Sigma Xi, and the American Physical Society. While he was at the University of Illinois he held industrial fellowships from Raytheon and Texas Instruments.

Sam S. Imamoto received an Engineering Associate of Arts degree from El Camino College El Camino College, Calif., in 1964.

He joined the Space Physics Laboratory, The Aerospace Corporation, El Segundo, Calif., in 1962. He is presently a Research Associate in the Space Particles and Fields Department. He has contributed to the design of space instrumentation orbited on more than 20 spacecraft. He was responsible for the design of the Aerospace Corp. experiment on ATS-1 as well as for the design of the Aerospace Corp. experiment on ATS-6. His responsibilities have included all phases of engineering effort from inception to spacecraft integration.

II. OPERATIONAL, INSTRUMENTAL AND DATA ANOMALIES

The various anomalies observed during the 1974-1977 interval in our data are described below. The anomalies have been grouped into several categories and have each been given a distinctive (if sometimes irreverent) name.

A. Instrumental Anomalies

This category describes malfunctions which are directly traceable to our experiment.

1. The E2 Anomaly

We found, early in the operations of ATS-6, that the E2 channel totally ceased counting for a few hours at a time on a given day. This anomaly was found to be associated with the temperature of our instrument: when our instrument was very cold, apparently an intermittent open-circuit can develop in the E2 data stream. This anomaly was observed only early after experiment turn-on (< 170, 1974). The practical consequence is that there are some zero hourly averages for E2 during mid-1974, which have been detected.

2. The E4 Anomaly

The E4 channel exhibited noisy behavior for some local times between Day 140, 1975 and Day 130, 1976. We suspect that the temperature of the E4 detector was sufficiently high so that the detector became noisy. Because of the UNH anomaly (see Section B1, below), we were not able to determine the temperature at which this (the E4) anomaly occurred. The practical consequences of the E4 anomaly is that we have ignored all E4 data between 140, 1975 and 130, 1976 in our work and have deleted these data from our input to NSSDC.

B. Operational Anomalies

The class of anomalies includes all malfunctions which affected our data, but whose sources were elsewhere in the ATS-6 spacecraft.

1. The UNH Anomaly

Turn-on of the University of New Hampshire (UNH) experiment on Day 169, 1974 caused a malfunction in the EME encoder. Specifically, word 189, which contained the health data from our experiment, was affected so that no valid measurements of the temperatures in our experiment were obtained after that date. The encoder apparently partially recovered around Day 139, 1977, however, the decision to operate the UNH experiment starting on Day 171, 1977, again destroyed Word 189. The practical consequences are that no temperature data from our experiment are available to aid in the analysis of other anomalies we have observed.

2. The HAC Anomaly

The operation of the Hughes Aircraft Company solar cell experiment on the ATS-6 EME caused a peculiar (and not understood) interaction, with the spacecraft data encoder which had the effect of dropping a "one" in the most significant bit of the E1 channel (only) at high counting rates. This occurred between 0030 and 0330 UT (during the early ATS-6 operation period) and was apparently associated with a mode change ("lockout") of the HAC experiment. Although only the E1 channel was affected, this anomaly apparently introduced a sufficient number of warning flags into the data tapes we received from Goddard, that our data processing program did not process the first three (UT) hours of data for days shortly after experiment turn-on. As a result, the first three (UT) hourly averages may be missing from the data for some fraction of 1974.

C. Data Anomalies

The anomalies described below are associated with malfunctions in the data processing systems on the ground as well as with introduction of noise into the data stream by telemetry noise or link dropouts.

1. Proton Data

The proton channels of our experiments, as expected, registered only very low countrates except during solar proton events (rare in 1974-1977) and except during some classes of magnetospheric disturbances (also relatively rare). Consequently, noisy data, if uncorrected, has a very

significant effect on long-term averages of the countrates. There has not been any systematic effort to remove noisy data points from the proton data, although we have edited out suspect hourly averages. Users of the proton data are hereby cautioned: proceed carefully, the counts you see may be but noise.

2. Mis-Labeled Data

Despite the best efforts of all concerned, tapes are occasionally mislabeled, not labeled in a consistent manner (date/day number), etc. We have tried to eliminate all such "malfunctions" using such tests as we considered appropriate, but there may well be some pathological cases (i. e., mis-identified days of data) that we did not detect. Users are encouraged to communicate their suspicions to us so that we may improve the data set.

3. Missing Days of Data, Partial Days

The data quality from ATS-6, although truly outstanding, was nevertheless not perfect. The users will find that the present data set contains some partial days of data and some days are entirely missing. The missing days are typically those which have defied processing for various reasons. After several attempts, we have simply called a halt and have asked NASA for replacement tapes. When these tapes arrive, they will be processed and the gaps will be filled. The problem should be put into perspective: at the time of writing (August 1977), for example, only 5 days of 1974 data have resisted processing and 4 days of 1975 data have not been processed. No doubt some interesting geophysical event will have occurred on one of those missing days, following the well-known perversity of nature.

4. Magnetometer Data

The magnetometer data incorporated into our data set was graciously provided by Dr. R. L. McPherron of UCLA. The field information was derived from the telemetry data as described in Section III.

Magnetometer data may not be associated with all days of our data because we have processed some quick-look tapes which did not include the magnetometer data (or, for that matter, any ephemeris or aspect information). There was also a malfunction in the UCLA magnetometer which we did not detect in a timely fashion. As a result, some of the magnetometer data appears strange because our processing routine did not compensate for the malfunction (failure of one axis). Upon notification of the malfunction, we changed the magnetometer data displays from the V, D, H system to one which presented the data in coordinates of the magnetometer axes (plus to total field). We suggest that users interested in the magnetometer data go directly to the UCLA magnetometer data held by NSSDC, rather than attempting to use our version of the UCLA data.

III. DESCRIPTION
OF DATA

III. DESCRIPTION OF DATA REDUCTION AND DATA FORMATS

A. Aerospace Corporation Experimental Tapes

Each data tape received from GSFC contains one day of data, including data from the Aerospace Corporation Omnidirectional Spectrometer and the UCLA Magnetometer, housekeeping data, and ephemeris data. The tapes contain several files, each file headed by a 132 8-bit word (18 CDC 60-bit words) coded title record, followed by many 64 second frames of data, 32x64 9-bit T/M words and 22 36-bit coded ephemeris words (321 CDC 60-bit words).

B. Data Reduction and Processing

Each record of T/M data contains one frame, 64 seconds, of data. From the original T/M Aerospace receives 32 measurements/second, including the following:

<u>Word</u>	<u>Description</u>
27, 28, 29	UT in milliseconds
1, 25	Counter, 0-63
23	Flag, 0 if no error
12	(E1, E2, E3, E4) x 16
15	(P1, P2, P3, P4, P5, P6, P7, P8) x 8
22	Temps, at seconds 53, 54, 55, 56
3, 4, 5	B _x , B _y , B _z , fine
6, 7, 8	B _x , B _y , B _z , medium

The data is checked to insure that the counters (words 1 and 25) are correct, the flag (word 23) is correct, and that the time (words 27, 28, 29) are increasing. If all this checks are passed that data is processed, otherwise not.

The processing includes conversion of the T/M data to fluxes for the omnidirectional spectrometer, gammas for the magnetometer, and degrees for the thermistors. In addition to the second by second values, frame averages, 5 minute averages, and one hour averages are calculated. These are used in detailed plots, and for our two data tape formats, the Detailed Data Tape Format and Master Data Tape Format described in section C.

1. The Ephemeris Data

The ephemeris data consists of 47 values for each 64 second frame, in the ORB/ATT format, detailed in Appendix A. In particular the radius, latitude and longitude are obtained from words 18, 19 and 20.

For the calculation of local time the day and year are taken from the title record, and the time in milliseconds from word 2 of the ephemeris data. Then the position of the sun in ECI coordinates is calculated, and compared with the satellite position in ECI coordinates, words 3, 5, and 7, to calculate the local time.

The attitude transformation matrix, to transform a vector from local vertical to spacecraft body axes, is read from words 36 to 44.

Finally, the matrix to transform from local vertical to dipole coordinates is calculated. This coordinate system has the z-axis parallel to the earth's dipole axis (north positive) and the x-axis chosen so that the satellite is in the x-z plane.

2. The Particle Measurements

The particle measurements are transmitted in the T/M as 9-bit floating point numbers. These T/M values are converted to counts, and then to fluxes, using the values below. Four electron measurements are made each second, and eight "proton" measurements are made each second. The energies and geometric factors for the 12 measurements are listed below. (Note that the electron multiplication factors differ from that given in Section I because they include a factor of 4 to convert from counts/.25 sec to counts/sec).

<u>Channel</u>	<u>Particle</u>	<u>Passband/ Threshold (MeV)</u>		<u>Factor</u>
E1	e	.140-.600	34.783	cm ² /sec-sr
E2	e	> .700	1146.1	cm ² /sec
E3	e	> 1.55	227.27	cm ² /sec
E4	e	> 3.90	58.140	cm ² /sec
P1	P	2.3-5.3	6.2500	cm ² /sec-sr
P2	P	3.4-5.3	6.2500	cm ² /sec-sr
P3	α	9.4-21.2	6.2500	cm ² /sec-sr
P4	P	12-26	222.22	cm ² /sec
P5	α	46-100	208.33	cm ² /sec
P6	P	20-52	53.193	cm ² /sec
P7	P	40-90	24.272	cm ² /sec
P8	α	13.4-21.2	6.2500	cm ² /sec-sr

3. The Magnetometer Measurements

The UCLA Magnetometer gives medium and fine readings for three axes once/second, or 64 samples/frame. The T/M values are converted to gammas in spacecraft coordinates. Then if the local vertical-spacecraft body axis transformation is available, the three components are rotated to local vertical, and then to "dipole" coordinates. If the local vertical-spacecraft body axis is not available, the magnitude of the field is calculated, and the three components set to -1.

The calibration coefficients used were obtained using a least-squares fit to processed magnetometer data supplied by R. McPherron. The toggling of the fine and medium readings was handled improperly, so an error as much as 16 gamma may occur on any reading, but the 5 minute and 1 hour averages should be unaffected.

C. The Data Tape Formats

1. The Detailed Data Tape

The Detailed Data Tape Format is shown in Appendix B. It contains the processed data on a frame by frame basis, followed by

5 minute and 1 hour averages. Generally there are 10 days of data per tape.

The electron and proton measurements are decommutated each frame, in order to keep the times correct. Only every fourth magnetometer measurement is copied. Time is monotonic increasing, and data is filled with -1's in cases of overlap.

After the frame data, there is one record of 0's to indicate the beginning of the 5 minute and 1 hour averages.

2. The Master Data Tape

The Master Data Tape Format is shown in Appendix C. It contains the hourly averages from the electron, proton and magnetometer data, one day per record. All the days for which there is data are in order chronologically on one tape. It is anticipated that this will be the more useful data for continuing studies.

These data have been examined in detail and all suspect data for the electron and proton measurements have been set to -1.

OUTPUT PARAMETER NO. 1

Name - Day Count of Year

Analytic Definition - This identifies the day on which the processed telemetry frame was transmitted by the spacecraft. The starting point for the count is 0000 hours of the first day of the calendar year (1 January).

Units - Days

Format - This is a nine-bit binary word with the most significant bit (MSB) leading. No sign bit exists.

OUTPUT PARAMETER NO. 2

Name - Milliseconds of Day

Analytic Definition - This identifies the time of day on which the processed telemetry frame was transmitted by the spacecraft. The starting point for this parameter is 0000 hours of the day specified in Output Parameter No. 1 (Day Count of Year).

Units - Milliseconds (Seconds x 10^{+3})

Format - This is a 27-bit binary word with the MSB leading. No sign bit exists.

OUTPUT PARAMETER NO. 3

Name - X-Coordinate

Analytic Definition - The X-component of the position vector of the ATS-F spacecraft expressed in an earth centered inertial (ECI) coordinate system defined below.

X-axis points to the first point of Aries true-of-date and lies in the equatorial plane of the earth

Z-axis points along the Polaris spin axis of the earth; the positive direction is north

Y-axis is chosen to complete a right-handed orthogonal set

Units - Tenths of kilometers (kilometers x 10^{+1})

Format - This is a 20-bit binary word. The first bit is used for the sign and the following nineteen bits for magnitude with the MSB leading.

OUTPUT PARAMETER NO. 4

Name - \dot{X} -Coordinate

Analytic Definition - The X-component of the velocity vector of the ATS-F spacecraft expressed in the ECI coordinate system described in the Analytic Definition of Output Parameter No. 3

Units - Meters per second

Format - This is a 16-bit binary word. The first bit is used for the sign and the following 15 bits for magnitude with the MSB leading.

OUTPUT PARAMETER NO. 5

Name - Y-Coordinate

Analytic Definition - The Y-component of the position vector of the ATS-F spacecraft expressed in the ECI coordinate system described in the Analytic Definition of Output Parameter No. 3

Units - Tenths of kilometers (kilometers $\times 10^{+1}$)

Format - This is a 20-bit binary word. The first bit is used for the sign and the following 19 bits for magnitude with the MSB leading.

OUTPUT PARAMETER NO. 6

Name - \dot{Y} -Coordinate

Analytic Definition - The Y-component of the velocity vector of the ATS-F spacecraft expressed in the ECI coordinate system defined in the Analytic Definition of Output Parameter No. 3

Units - Meters per second

Format - This is a 16-bit binary word. The first bit is used for the sign and the following 15 bits for magnitude with the MSB leading.

OUTPUT PARAMETER NO. 7

Name - Z-Coordinate

Analytic Definition - The Z-component of the position vector of the ATS-F spacecraft expressed in the ECI coordinate system described in the Analytic Definition of Output Parameter No. 3

Units - Tenths of kilometers (kilometers $\times 10^{+1}$)

Format - This is a 20-bit binary word. The first bit is used for the sign and the following 19 bits for magnitude with the MSB leading.

OUTPUT PARAMETER NO. 8

Name - $\dot{\bar{Z}}$ -Coordinate

Analytic Definition - The \bar{Z} -component of the velocity vector of the ATS-F spacecraft expressed in the ECI coordinate system defined in the Analytic Definition of Output Parameter No. 3

Units - Meters per second

Format - This is a 16-bit binary word. The first bit is used for the sign and the following 15 bits for magnitude with MSB leading.

OUTPUT PARAMETER NO. 9

Name - Yaw

Analytic Definition - The first of three rotations about ATS-F body axes that are used to define ATS-F attitude relative to the Local Vertical (LV) coordinate system defined below.

Z_C points along the local vertical toward the center of mass of the earth

X_C points east parallel to the earth's equatorial plane

Y_C is chosen to complete a right-handed orthogonal set (nominally points south)

The Euler rotations, in the sequence of their application, are as follows:

Yaw - rotation about the spacecraft body Z-axis (Z_B)

Roll - rotation about the spacecraft body X-axis (X_B)

Pitch - rotation about the spacecraft body Y-axis (Y_B)

Units - Thousandths of a degree (degrees $\times 10^{+3}$). Yaw is always taken to be positive ranging from 0 to 360 degrees.

Format - This is a 20-bit binary word with MSB leading. No sign bit exists.

OUTPUT PARAMETER NO. 10

Name - Yaw Rate

Analytic Definition - The time rate of change of the yaw Euler angle defined in the Analytic Definition of Output Parameter No. 9

Units - Thousandths of a degree per minute (degrees per minute x 10^{+3})

Format - This is a 16-bit binary word. The first bit is used for the sign and the following 15 bits for magnitude with MSB leading.

OUTPUT PARAMETER NO. 11

Name - Roll

Analytic Definition - The second rotation in the Euler sequence used to define ATS-F attitude. This rotation is about the spacecraft body X-axis (X_p). The attitude is relative to the LV coordinate system defined in the Analytic Definition of Output Parameter No. 9

Units - Thousandths of a degree (degrees x 10^{+3})

Format - This is a 20-bit binary word. The first bit is used for the sign and the following 19 bits for magnitude with MSB leading.

OUTPUT PARAMETER NO. 12

Name - Roll Rate

Analytic Definition - The time rate of change of the roll Euler angle defined in the Analytic Definition of Output Parameter No. 11

Units - Thousandths of a degree per minute (degrees per minute x 10^{+3}).

Format - This is a 16-bit binary word. The first bit is used for the sign and the following 15 bits for magnitude with the MSB leading.

OUTPUT PARAMETER NO. 13

Name - Pitch

Analytic Description - The third rotation in the Euler sequence used to define ATS-F attitude. This rotation is about the spacecraft body Y-axis. The attitude is relative to the LV coordinate system defined in the Analytic Definition of Output Parameter No. 9

Units - Thousandths of a degree (degrees x 10^{+3}).

Format - This is a 20-bit binary word. The first bit is used for the sign and the following 19 bits for magnitude with the MSB leading.

OUTPUT PARAMETER NO. 14

Name - Pitch Rate

Analytic Definition - The time rate of change of the pitch Euler angle defined in the Analytic Definition of Output Parameter No. 13

Units - Thousandths of a degree per minute (degrees per minute $\times 10^{+3}$).

Format - This is a 16-bit binary word. The first bit is used for the sign and the following 15 bits for magnitude with the MSB leading.

OUTPUT PARAMETER NO. 15

Name - Z_B -Axis Intercept Latitude

Analytic Definition - The latitude of the intercept point of a line coincident with the spacecraft body Z-axis (Z_B) and the surface of the earth. An ellipsoidal model of the earth is used.

Units - Hundredths of a degree (degrees $\times 10^{+2}$).

Format - This is an 18-bit binary word. The first bit is used for the sign and the following 17 bits for magnitude with MSB leading.

OUTPUT PARAMETER NO. 16

Name - Z_B -Axis Intercept Longitude

Analytic Description - The longitude of the intercept point of a line coincident with the spacecraft body Z-axis (Z_B) and the surface of the earth. An ellipsoidal model of the earth is used.

Units - Hundredths of a degree (degrees $\times 10^{+2}$). Longitude is always positive measured East from Greenwich and lies in the range 0 to 360 degrees.

Format - This is an 18-bit binary word with the MSB leading. No sign bit exists.

OUTPUT PARAMETER NO. 17

Name - Rotation of Y_B -Axis from North

Analytic Definition - The angle between the following planes.

Plane 1: Plane formed by the spacecraft Z-axis (Z_B) and the local north vector (i.e., $-Y_C$, see Analytic Definition of Output Parameter No. 9).

Plane 2: Plane formed by the spacecraft Z-axis (Z_B) and Y-axis (Y_B).

Units - Hundredths of a degree (degrees $\times 10^{+2}$).

Format - This is an 18-bit binary word with MSB leading. No sign bit exists.

OUTPUT PARAMETER NO. 18

Name - Height Above Subsatellite Point

Analytic Definition - The height of the ATS-F spacecraft above the surface of the earth measured along the line between the spacecraft and the center of mass of the earth. An ellipsoidal model of the earth is used.

Units - Kilometers

Format - This is an 18-bit binary word. No sign bit exists.

OUTPUT PARAMETER NO. 19

Name - Subsatellite Latitude

Analytic Definition - The geodetic latitude of the intercept point on the surface of the earth of a line between the spacecraft and the center of mass of the earth. An ellipsoidal model of the earth is used.

Units - Hundredths of a degree (degrees $\times 10^{+2}$).

Format - This is an 18-bit binary word. The first bit is used for the sign and the following 17 bits for magnitude with the MSB leading.

OUTPUT PARAMETER NO. 20

Name - Subsatellite Longitude

Analytic Definition - The longitude of the intercept point on the surface of the earth of a line between the spacecraft and the center of mass of the earth. An ellipsoidal model of the earth is used.

Units - Hundredths of a degree (degrees $\times 10^{+2}$). Longitude is always positive measured east from Greenwich and lies between 0 and 360 degrees.

Format - This is an 18-bit binary word with the MSB leading. No sign bit exists.

OUTPUT PARAMETER NO. 21

Name - Range from Spacecraft to Z_B -Axis Intercept

Analytic Description - The distance between the spacecraft and the point defined by the intersection of the Z-axis (Z_B) with the earth's surface given in the Analytic Descriptions of Output Parameters Nos. 15 and 16.

Units - Tenths of a kilometer (kilometers $\times 10^{+1}$).

Format - This is a 20-bit binary word with MSB leading. No sign bit exists.

OUTPUT PARAMETER NO. 22

Name - Cross-Polarization Angle

Analytic Description - The angle between the ATS-F receiver and a vertically polarized antenna located at the Z-axis (Z_B) intercept point. It is the acute angle between the following two planes:

Plane 1: Defined by (a) center of mass of the earth and (b) the spacecraft body Z-axis (Z_B)

Plane 2: Defined by (a) the location of an antenna element in the spacecraft body X-Y plane (X_B - Y_B), and (b) the spacecraft body Z-axis (Z_B).

Units - Hundredths of a degree (degrees $\times 10^{+2}$), in the range 0 to 360 degrees.

Format - This is a 16-bit binary word with the MSB leading. No sign bit exists.

OUTPUT PARAMETER NO. 23

Name - Antenna Pattern Angle θ

Analytic Description - The angle between the spacecraft Z-axis (Z_B) and the vector to a preselected ground station. The ground station coordinates will be user specified and available upon request.

Units - Hundredths of a degree (degrees $\times 10^{+2}$).

Format - This is an 18-bit binary word with the MSB leading. No sign bit exists.

OUTPUT PARAMETER NO. 24

Name - Antenna Pattern Angle \emptyset

Analytic Description - The angle between the following two planes.

Plane 1: Plane defined by the spacecraft body X and Z axes (X_B, Z_B)

Plane 2: Plane defined by the vector to a preselected ground station and the spacecraft body Z-axis (Z_B)

The ground station coordinates will be user specified and available upon request.

Format - This is an 18-bit binary word with the MSB leading. No sign bit exists.

OUTPUT PARAMETER NO. 25

Name - NFX

Analytic Description - The X-component (i_{NF} direction) of the unit vector to the sun expressed in the Quartz experiment's coordinate system for the sensor assembly on the north face of the Earth Viewing Module (EVM).

Units - Thousandths of a unit (unit $\times 10^{+3}$).

Format - This is a 12-bit binary word. The first bit is used for the sign and the following 11 bits for magnitude with the MSB leading.

OUTPUT PARAMETER NO. 26

Name - NFY

Analytic Description - The Y-component (j_{NF} direction) of the unit vector to the sun expressed in the Quartz experiment's coordinate system for the sensor assembly on the north face of the EVM.

Units - Thousandths of a unit (unit $\times 10^{+3}$).

Format - This is a 12-bit binary word. The first bit is used for the sign and the following 11 bits for magnitude with the MSB leading.

OUTPUT PARAMETER NO. 27

Name - NFZ

Analytic Description - The Z-component (k_{NF} direction) of the unit vector to the sun expressed in the Quartz experiment's coordinate system for the sensor assembly on the north face of the EVM.

Units - Thousandths of a unit (unit $\times 10^{+3}$).

Format - This is a 12-bit binary word. The first bit is used for the sign and the following 11 bits for magnitude with the MSB leading.

OUTPUT PARAMETER NO. 28

Name - EFX

Analytic Description - The X-component (\underline{i} direction) of the unit vector to the sun expressed in the ATF Experiment's coordinate system for the sensor assembly on the east face of the EVM.

Units - Thousandths of a unit (unit x 10^{+3}).

Format - This is a 12-bit binary word. The first bit is used for the sign and the following 11 bits for magnitude with the MSB leading.

OUTPUT PARAMETER NO. 29

Name - EFY

Analytic Description - The Y-component (\underline{j} direction) of the unit vector to the sun expressed in the ATF Experiment's coordinate system for the sensor assembly on the east face of the EVM.

Units - Thousandths of a unit (unit x 10^{+3}).

Format - This is a 12-bit binary word. The first bit is used for the sign and the following 11 bits for magnitude with the MSB leading.

OUTPUT PARAMETER NO. 30

Name - EFZ

Analytic Description - The Z-component (\underline{k} direction) of the unit vector to the sun expressed in the ATF Experiment's coordinate system for the sensor assembly on the east face of the EVM.

Units - Thousandths of a unit (unit x 10^{+3}).

Format - This is a 12-bit binary word. The first bit is used for the sign and the following bits for magnitude with the MSB leading.

OUTPUT PARAMETER NO. 31

Name - Yaw Uncertainty

Analytic Description - The statistical uncertainty in the estimate of the yaw angle. It is the square root of the diagonal element of the state covariance matrix corresponding to the yaw state.

Units - Thousandths of a degree (degrees x 10^{+3}).

Format - This is a 12-bit binary word with the MSB leading. No sign bit exists.

OUTPUT PARAMETER NO. 32

Name - Roll Uncertainty

Analytic Description - The statistical uncertainty in the estimate of the roll angle. It is the square root of the diagonal element of the state covariance matrix corresponding to the roll state.

Units - Thousandths of a degree (degrees x 10^{+3}).

Format - This is a 12-bit binary word with the MSB leading. No sign bit exists.

OUTPUT PARAMETER NO. 33

Name - Pitch Uncertainty

Analytic Description - The statistical uncertainty in the estimate of the pitch angle. It is the square root of the diagonal element of the state covariance matrix corresponding to the pitch state.

Units - Thousandths of a degree (degrees x 10^{+3}).

Format - This is a 12-bit binary word with the MSB leading. No sign bit exists.

OUTPUT PARAMETER NO. 34

Name - Offset Pointing Angle, α

Analytic Description - The angle between the line of sight to the subsatellite point (output parameters 19 and 20) and the spacecraft Z-axis (Z_B).

Units - Hundredths of a degree (degrees x 10^{+2}).

Format - This is a 14-bit binary word with the MSB leading. No sign bit exists.

OUTPUT PARAMETER NO. 35

Name - Attitude Sensor ID

Analytic Description - This identifies the attitude sensors whose data is being utilized in the attitude estimation process.

Units - None (binary flags)

Format - This is a string of 22 bits. Each bit corresponds to a specific sensor on ATS-F and indicates whether that sensor's output is used in the attitude estimation process. The state "1" indicates it is used. The bits refer to the following sensors in the indicated order.

<u>Bit No.</u>	<u>Sensor</u>
1	Earth Sensor
2	Polaris Sensor No. 1
3	Polaris Sensor No. 2
4	Digital Sun Sensor No. 1
5	Digital Sun Sensor No. 2

19	Fine Sun Sensor No. 2
20	Rate Gyro Assembly No. 1
21	Rate Gyro Assembly No. 2
22	Spare

OUTPUT PARAMETERS NOS. 36 THROUGH 44

Name - Elements of the Attitude Transformation Matrix (a_{ij})

Analytic Description - Elements of the transformation matrix from the local vertical (L-V) coordinate frame to the spacecraft body coordinate frame. The matrix is of the form:

$$[A] = \begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix}$$

The matrix transforms a vector in the local vertical coordinate frame (\bar{V}_{L-V}) to a vector in the spacecraft body frame (\bar{V}_B) according to the following relationship:

$$\bar{V}_B = [A] \bar{V}_{L-V}$$

Units - Hundred thousandths of a unit (unit x 10^{+5})

Format - Each element is an 18-bit binary word. The first bit is used for the sign and the following 17 bits for magnitude with the MSB leading.

OUTPUT PARAMETER NO. 45

Name - Program Status

Analytic Description - Code words for internal use by attitude generation personnel to identify program modifications

Units - None. Code words.

Format - To be determined.

OUTPUT PARAMETER NO. 46

Name - Calibration Identifier

Analytic Description - Code words for internal use by attitude generation personnel to identify telemetry calibration curves used in generating attitude

Units - None. Code words.

Format - To be determined

OUTPUT PARAMETER NO. 47

Name - Misalignment Identifier

Analytic Description - Code words for internal use by attitude generation personnel to identify attitude sensor misalignment sets used in generating attitudes

Units - None. Code words.

Format - To be determined

APPENDIX B.

DETAILED DATA TAPE FORMAT

Each day is one file of many 288 CDC 60-bit records.

Record 1:

<u>Word</u>	<u>Type</u>	<u>Description</u>
1- 18	Bits	The original title record (132 8-bit characters) plus 24 "0" bits.
19	Hollerith	Date of data
20	"	Date Processed by Aerospace Corporation
21	"	Tape Number Assigned by Aerospace Corporation
22-288		Fill, "0"s.

Records 2 - Number of Frames, N, +1.

<u>Word</u>	<u>Type</u>	<u>Description</u>
1	Integer	Day of Year
2	"	Year
3	Real	UT, seconds, of ephemeris, or -1.
4	"	Radius, ER, or -1.
5	"	Latitude, Deg., or -1.
6	"	Longitude, Deg., or -1.
7	"	Local Time, Hrs., or -1.
8	"	0.
9- 72	"	UT, seconds, or -1.
73-136	"	(E1, E2, E3, E4) x 16, or -1.
137-200	"	(P1, P2, P3, P4, P5, P6, P7, P8) x 8, or -1.
201-216	"	B _x

MODULATION OF TRAPPED ENERGETIC ELECTRONS AT
6.6 R_e BY THE DIRECTION OF THE
INTERPLANETARY MAGNETIC FIELD

G. A. Paulikas and J. B. Blake
Space Sciences Laboratory

The Aerospace Corporation
El Segundo, California

Abstract. Energetic ($E > 1.6$ MeV, > 3.9 MeV) trapped electron fluxes observed at the synchronous altitude during 1974 and 1975 by an experiment aboard ATS-6 exhibit a modulation in intensity which is correlated with the passage of sector structure boundaries of the interplanetary magnetic field past the earth. The electron fluxes reach equilibrium intensities during the time the magnetosphere is in a given IMF sector which are highest in the fall for (+) sectors and highest in the spring for (-) sectors.

Introduction

We have observed a periodicity in the magnetospheric energetic electron fluxes ($E > 1$ MeV) at 6.6 R_e associated with the passage of sector boundaries (Wilcox, 1968) of the interplanetary magnetic field. The changes in electron flux, associated with each boundary passage, are the major intensity excursions of electron fluxes during conditions of low solar activity. Furthermore, maximum intensity reached by the energetic electrons in the intervals between sector boundary passage is dependent upon the direction of the interplanetary magnetic field.

Changes in the intensity of trapped energetic electrons which could be associated with changes in the conditions existing in the interplanetary medium, and thus ultimately with the properties of magnetic field and plasma structure of the solar atmosphere, have been reported by Williams (1966) and Rothwell (1968). The observations which led these authors to conclude that the outer zone was markedly responsive to the sector structure of the interplanetary medium were obtained in the time interval near solar minimum in the middle 1960's. In 1968 we used ATS-1 data on energetic electrons which were obtained between late 1966 and early 1968 at the synchronous orbit in an attempt to verify the conclusions of Williams and Rothwell. Although the experimental situation in a synchronous orbit is somewhat "cleaner" than observations made aboard low-altitude spacecraft or high-altitude spacecraft in elliptical orbits, we failed to establish that any close correlation existed between changes in the electron fluxes observed at 6.6 R_e and changes in the direction of the interplanetary field. To be sure, sector boundary passages did give rise to major excursions in the flux levels of energetic

electrons, however equally large excursions also occurred when there were no IMF boundaries in the vicinity of the earth. These conclusions, now more than five years old, were once again checked in the course of the present study using the sector boundary catalog prepared by Svaalgaard (1975)

We were thus surprised to find that omnidirectional electron fluxes (hourly averages), as determined from data obtained by The Aerospace Corporation experiment aboard ATS-6 in 1974 and 1975, exhibit a very pronounced periodicity which is very clearly associated with the passage of interplanetary magnetic-field sector boundaries. ATS-6 was stationed at 6.6 R_e and at 94°W during the time period under consideration, the experiment which yielded the data presented here is fully described in Paulikas et al. (1975). Figure 1 illustrates the observations made at noon local time. Similar plots have been constructed for other local times and these plots exhibit identical periodicities. A limited set of data from the synchronous spacecraft ATS-1, located at 150°W, and ATS-5, located at 105°W, also are available to us for portions of the time period under discussion. (ATS-5 data were graciously provided by C. E. McIlwain). Such comparisons as we have made indicate that ATS-1, ATS-5 and ATS-6 all observe the modulation; clearly the entire outer magnetosphere is involved. Evidently, strong, periodic modulation of the outer-zone trapped-particle intensities by the interaction between the magnetosphere and the interplanetary medium is a function of the general level of solar activity and emerges as the dominant process affecting the outer zone during conditions of solar minimum. During periods of high solar activity, the periodic modulation is masked by the more-or-less irregular occurrence of magnetic storms which destroy the coherence that the energetic electron fluxes would otherwise be expected to develop in response to interplanetary conditions.

Discussion

The outer-zone energetic electrons observed by ATS-6 are one of the end products of the interaction of the solar wind with the earth's magnetosphere. The magnetospheric substorm is the basic process which energizes magnetospheric plasma and transports these energetic particles into the stable-trapping region of the magnetosphere (McPherron et al., 1975). In the

absence of magnetic storms, the temporal evolution of the energetic electron population is a measure of the relative strength of the source (i.e., substorms) as compared to particle sinks. Our observations can be considered as representing an averaged, smoothed output of the solar wind-magnetosphere engine, with the equilibrium level of energetic electron fluxes indicative of the rate of occurrence of substorms, and hence the rate of "quiescent" energy transfer into the magnetosphere (Russell, 1974). In contrast, the changes in the electron fluxes at the time of boundary passage are associated with major disruption of the energetic electron population by magnetic storms.

We interpret our results using the phenomenological studies of Arnoldy (1974), Burton et al., (1975), Burch (1973), and Russell and McPherron (1973). The thrust of the findings of these authors, as summarized in the review of Russell (1974), is that the energy flow from the solar wind into magnetosphere mimics in some ways the behavior of a half-wave rectifier familiar in electronic applications. The input of energy into the magnetosphere proceeds only if the magnetosphere sees a southward component of the interplanetary magnetic field; a northward IMF component apparently inhibits the transfer of energy into the magnetosphere. Thus, to first approximation, the dynamics of the magnetosphere are a function of the orientation of the magnetosphere in solar-equatorial coordinates (the natural coordinates of the flow of the solar wind plasma). The geometrical arguments and coordinate transformations required to determine whether the magnetosphere sees a net northward or net southward component of the interplanetary magnetic field are somewhat complex and the reader should refer to the paper of Russell and McPherron (1973) for a complete and critical discussion of the problem. For our present purposes, we can summarize briefly: the interaction between solar wind and magnetosphere is expected to be strongest when the magnetosphere is immersed in a southward pointing interplanetary field. This occurs during northern hemisphere spring, when the earth is in a (-) sector of the interplanetary field, and in the fall, when the earth is in a (+) sector of the interplanetary field.

The data obtained during the fall of 1974 and presented in Figure 1 are consistent with this picture. The energetic electron fluxes appear to build up to higher levels during (+) sectors (i.e., generally southward IMF) than during (-) sectors. Note also that (-) to (+) sector transitions cause much deeper depressions in the electron flux than (+) to (-) transitions. Examination of the behavior of D_{st} for this period shows that a magnetic storm is associated with each (-) to (+) transition.

A limited set of data obtained in early 1975 (Fig. 2) verifies the expectation that in spring (-) sectors are more effective generators of energetic electron fluxes. The IMF sector structure during the time period covered by Fig. 2 is broken by days of mixed polarity, nevertheless, the data of Fig. 2 are, if anything, an even more striking demonstration that the level of energetic electron flux at 6.6

Figure 1. Hourly averages of energetic electron count rates observed in the late summer and fall of 1974 by ATS-6 and ATS-1 are plotted as a function of Day Number, 1974. Also plotted (at the top of the figure) are the polarity of the interplanetary magnetic field as inferred by Svalgaard (1975), the daily sum of K_p and the range of D_{st} for each day. Local time for all particle data is local noon, the sector boundary transitions are assumed to occur at 0000 UT for the days indicated. Circles and triangles are ATS-6 observations of > 3.9 and > 1.6 MeV electrons respectively, squares are ATS-1 observations of > 1.9 MeV electrons. For emphasis we have shaded those portions of the curves where $E > 1.6$ MeV count rates exceed $10^2/\text{sec}$ and $E > 3.9$ MeV count rates exceed $10/\text{sec}$.

R_e is a strong function of the direction of the interplanetary field.

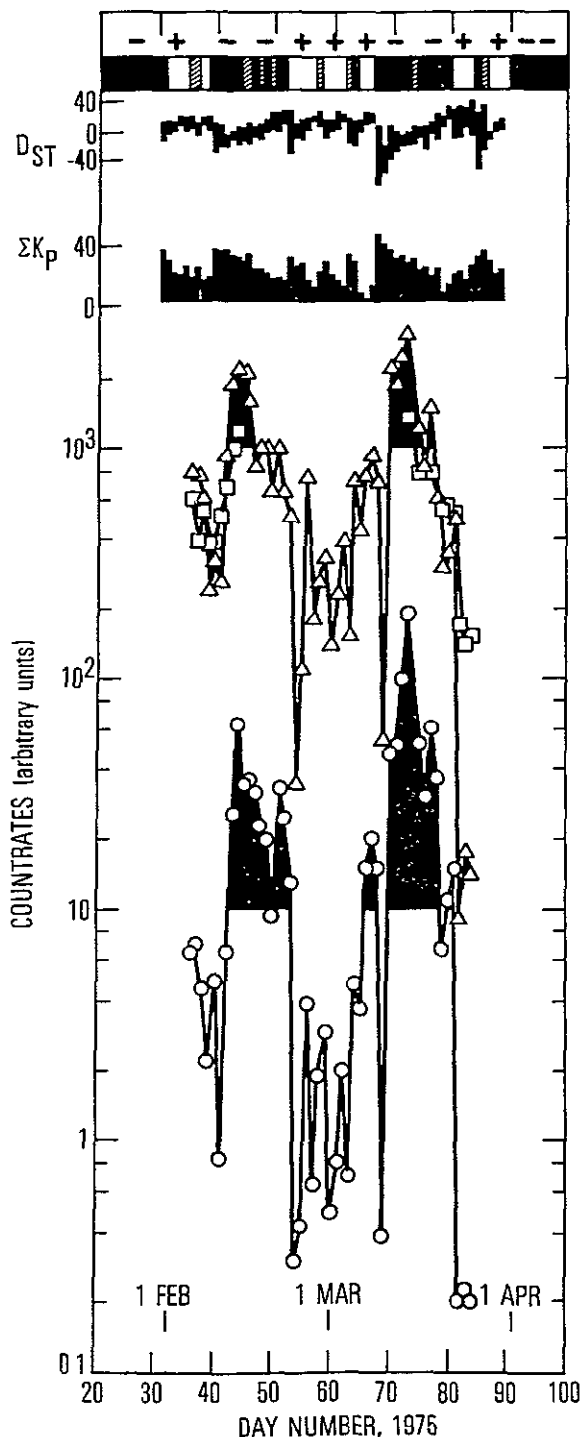

Figure 2. Hourly averages of energetic electron count rates observed in the spring of 1975 by ATS-6 and ATS-1. All other comments from the caption of Fig 1 apply. The IMF sector structure during this period exhibited some days of mixed polarity, these days are indicated by cross-hatching

At this stage of the data analysis we cannot unequivocally separate temporal changes in the electron flux from changes in the geometry of the trapping region. The work of Owens and Frank (1968) very clearly shows that the region around the earth containing energetic particles expands and contracts. ATS-6 observations, by themselves, cannot provide information regarding the extent of the trapping region. If we focus our attention on the properties of the region near ATS-6 we find, using data from the UCLA magnetometer on ATS-6 (graciously made available by R L McPherron), that during the time periods of Figs. 1 and 2 there do not appear to be any significant changes in the local field geometry at ATS-6 which are a function of the gross direction of the interplanetary field inferred by Svalgaard (1975).

It must be recalled that, because of drift shells splitting, a measurement of the omnidirectional flux by our experiment at one local time at the synchronous orbit represents the sum of the flux which exists over a range of L values at other local times. Our data have global rather than local properties. In addition, it is well known that large drift loss cones can develop in the angular distribution at synchronous altitude because of the proximity of the synchronous orbit to the trapping boundary. Such changes in the angular distribution would be interpreted by our experiment as flux changes. There are suggestions in the data, for example, in comparisons of relative flux changes at ATS-1, ATS-5 and ATS-6 as a function of IMF direction, that there may indeed be changes in the average pitch-angle distribution of energetic electrons (and therefore changes in the geometry of the trapping region) which are a function of the interplanetary field direction.

Correlations between the state of the magnetosphere and interplanetary conditions appear to be most successful when the magnetospheric parameters used in such studies represent some global characteristic of the magnetosphere. The auroral electrojet index A_e (Arnoldy, 1971), properties of polar magnetic fields (Burch, 1973), the size of the polar cap (Akasofu, 1975) and the D_{st} index (Burton, et al, 1975) are examples of such global quantities. We can now add the energetic electron fluxes at the synchronous orbit to the list of indicators of the coupling strength between the interplanetary medium and the magnetosphere.

The changes in the energetic electron flux at $6.6 R_e$ should be reflected in corresponding changes in the intensity of the energetic electrons precipitating into the atmosphere. Hence, one might expect to see aeronomic effects in and below the D-region at high latitudes (the depth in the atmosphere reached by precipitating relativistic electrons is ≈ 50 km.) The magnitude of such aeronomic effects should be a function of the direction of the interplanetary magnetic field.

Acknowledgements

The efforts of many people made our experiment on ATS-6 a success. We are particularly grateful

Abstract

A description of the energetic (140 kev to > 3.9 Mev) electron environment observed at the synchronous altitude during the 1974-1977 time interval is presented. These results were obtained by an experiment carried on the geostationary ATS-6 spacecraft. Observations were made at several longitudes. Electron fluxes exhibit a complex temporal behavior ranging in time scale from a diurnal variation to a semi-annual variation. Average fluxes are computed and compared with earlier studies and models.

Energetic Electrons at the Synchronous Altitude 1974-1977

I. Introduction

The synchronous orbit, because of its obvious utility for terrestrial applications, is undoubtedly the single most heavily populated orbit in space. Many spacecraft, spread over longitude, are in this orbit today, and the plans of various nations (Ref. 1, Ref. 2) emphasize an even heavier utilization of it for future communications, earth observations, meteorology, and data relay spacecraft. It is clear that the investment in such space systems is likely to run into the billions of dollars.

The premium on a precise, quantitative understanding of the space environment and the impact of the environment on space systems is enormous. Even savings of fractions of a percent, derived as a result of better information regarding the energetic radiation (for example, extending the life of a spacecraft and thus decreasing the replenishment rate) translate directly into savings which run into the tens of millions of dollars.

The purpose of this report is to summarize, in a format useful to the designers and operators of synchronous orbiting of space systems, the observations of energetic electrons at the synchronous altitude made by The Aerospace Corporation particle spectrometer flown on the ATS-6 spacecraft. Preliminary results have been reported in a series of internal reports (Refs. 3-8). In this report we shall concentrate on defining the average properties of the electron population as it existed in the 1974-1977 time interval at the synchronous orbit. Thus this report can be viewed as a sequel to earlier work (Refs. 9-12) which treated the properties of the particle population at the synchronous orbit during earlier epochs. It seems useful to begin by describing some of the salient features of the ATS-6 observing program which we conducted and to point out how the present data and results may be similar to, or differ from, earlier work because of differences in epoch, instrumentation, spacecraft orientation and the location of the spacecraft in longitude.

The observations described here were made between mid-1974 and early 1977. This time interval straddled to solar minimum (as defined by sunspot number) (Fig. 1). In contrast, earlier observation of energetic radiation at the synchronous orbit made by

instruments aboard ATS-1 and ATS-5 were made during times near the peak of solar activity: late 1966 to early 1968 in the case of ATS-1 and mid 1969 to early 1972 in the case of ATS-5. As is well known, the magnetosphere is relatively more quiescent during periods of low solar activity as contrasted to the time period near solar maximum. As we shall see below, periodic manifestations of solar-wind magnetosphere interactions emerge prominently in the ATS-6 data; in contrast, impulsive solar events which occur at frequent intervals during solar maximum and tend to mask the more regular features of magnetospheric dynamics are infrequently observed in the present data set. The ATS-6 data is thus unique because it represents the first observations of the particle populations of the synchronous orbit made during the interval near solar minimum.

The instrumentation used to obtain our data has been described elsewhere (Ref. 13); a brief summary of the relevant features is given in Appendix A. Briefly, we measured the directional fluxes of electrons in the 140-600 keV interval and the omnidirectional fluxes above thresholds of 700 keV, 1.55 MeV and 3.9 MeV. Energetic proton data were also obtained (during solar proton events; these data are not discussed here).

The ATS-6 was earth oriented so that the axes of the detectors were pointed radially outward along the earth-satellite line. Thus the (directional) 140-600 keV channel (E1) measured only one segment of the angular distribution, the precise segment depending on the (rather variable) orientation of the local magnetic field with respect to the detector axis. The omnidirectional fluxes (E2, E3, E4) obtained from the ATS-6 data were obtained from countrates registered by particles which could reach the detectors through a 2π steradian acceptance angle looking out along the earth-satellite line. In contrast, on ATS-1, for example, the rapid spin of the spacecraft coupled with a relatively slow count accumulation time served to form a true average of the in situ radiation.

During the period covered by our data, the ATS-6 spacecraft was moved several times to different longitudes. Because the geographic equator does not coincide everywhere with the geomagnetic equator, a spacecraft at the synchronous orbit may be at significantly different magnetic latitudes, depending on the longitude at which the spacecraft is stationed. ATS-6 observations began while the spacecraft was on the

equator at 94°W , where the magnetic latitude is about 11° . Subsequently the spacecraft was moved to 35°E and finally to 140°W . At both of these locations the magnetic equator is nearly coincident with the geographic equator.

The displacement of the spacecraft as little as 11° off the magnetic equator has a significant effect on the observations. We find that the geomagnetic field may quite often, particularly near local midnight, assume a configuration with a strong radial component, i.e. the magnetic field at $6.6 R_e$ appears, at these times, to assume a configuration expected to be found near the magnetotail. Such tail-like configurations are characterized by the absence of very energetic electrons. The fluxes observed at 94°W , i.e. somewhat off the magnetic equator, exhibit a significantly more dynamic behavior on the timescale of a day than seen at the magnetic equator where the geomagnetic field exhibits a more regular behavior, however, the long-term average fluxes do not reflect a very significant longitudinal difference. Spacecraft longitude is taken as a parameter in the data analysis, although, as we shall see below, temporal variations in the average particle fluxes are considerably larger than effects due to change in longitude.

For the purposes of this report, we have formed hourly averages, centered on the half hour, of all the electron data presently available to us. These hourly averages are the basic material from which further analysis proceeds. Daily averages, running 27 day averages, probability distributions are all formed from hourly averages.

II. Overview of the Observations

Figures 2 through 5 give an overview of the observations of energetic electrons from mid 1974 through early 1977. Plotted here are daily averages of the electron fluxes, together with data on the sector structure of the interplanetary magnetic field as a function of time. The location in longitude of ATS-6 and the periods of spacecraft movement are indicated on the figures and separately summarized in Table I.

The dynamic nature of the energetic electron fluxes, particularly at the higher energies, is immediately apparent. The dominant periodicity (in addition to the diurnal variations (see Refs. 11 and 15) which is not visible on a plot of daily averages) is the

TABLE I

ATS-6 Geographic and Geomagnetic Locations

Time Interval	Geographic Longitude	Magnetic Latitude*
Day 165, 1974-140, 1975	94°W	11°
Day 140, 1975-180, 1975	In transit	—
Day 180, 1975-214, 1976	35°E	5°
Day 214, 1976-330, 1976	In transit	—
Day 330, 1976-present	140°W	0°

* Derived from UCLA ATS-6 Magnetometer Data
(Courtesy R. L. McPherron)

strong modulation of the energetic electron fluxes on a timescale corresponding to the solar rotation period as well on a timescale consistent with either a two- or four-sector structure of the interplanetary field. (The effects of the interplanetary sector structure on the energetic particle population has been discussed previously in Ref. 11.).

It will be immediately appreciated by the reader that long term averages of these data, used for the purposes of accurate estimates of the radiation environment, must be approached with caution because of the large variation in the fluxes occurring on several timescales.

If we now form 27-day running averages of the data presented above, we obtain Figure 6 through 9. In these figures we again see the strong effects of solar rotation-to-rotation variability of the electron fluxes. This effect is particularly noticeable in the data for the more energetic electrons and stands out particularly well in late 1976 - early 1977. Also visible is a semi-annual variation in the energetic electron fluxes, with a maxima found near the equinoxes and minima near the solstices. To be sure, the moves of the spacecraft complicate the determination of the amplitude of this variation but it appears that the semi-annual variation is comparable to, if not greater than, the longitudinal effect. The semi-annual variation in the electron flux is presumably but a reflection of the well known semi-annual variation in geomagnetic activity (Ref. 17).

III. Average Fluxes and $P(F > F_x)$ Distributions

Using the data base discussed above, we have computed the probability distributions $P(F)$ and $P(F > F_x)$ in a manner analogous to that first described by in Ref. 18. $P(F > F_x)$ is the probability of observing a flux greater than F_x for some particular energy threshold, while $P(F)$ is the differential probability distribution. These curves have been computed for the several time intervals of interest and are presented as Figs. 10 through 15. Also computed, and indicated on the figures are u , the mean of $\log_{10} F$, J , the \log_{10} of the mean flux and s , the standard deviation about u . Note, from the $P(F)$ curves that the distribution is not necessarily gaussian in $\log_{10} F$, in contrast to assumptions made in analyses of earlier data sets.

Table II summarizes the data presented in Figs. 10-15, while Fig. 16 presents spectra of the average flux for the various longitudes and time intervals covered by our data, together with the spectrum predicted by the AE-4 model (Ref. 9, 10). The points noted below can serve as a summary of our findings.

1. At energies greater than about 1.5 Mev, the ATS-6 data indicate the presence of a somewhat harder electron spectrum than the AE-4 model would predict. At energies below ≈ 1.5 Mev, our data indicate, in general, fewer electrons than AE-4. These conclusions are, however, tempered by the fact that the electron fluxes are highly variable and one can find significant time intervals (for example the late 1966 - early 1967 interval illustrated in Figs. 14 and 15) where the spectral shape at the higher energies approached that which one might expect from AE-4.
2. Longitudinal effects (caused by differences in magnetic latitude) in the mean flux are relatively minor. This conclusion must be tempered by the fact that no systematic analysis of simultaneous observations made at several longitudes has yet been carried out. There is some limited evidence (based on ATS-1/ATS-6 comparisons, Refs. 3, 12) that longitudinal flux differences ($150^{\circ}\text{W}/94^{\circ}\text{W}$) may be as large as a factor of two.
3. Although the mean fluxes observed may not be similar, the probability distributions $P(F > F_x)$ differ show systematic differences because there are far more flux dropouts off the equator. The differences are significant only near the $P(F > F_x) \approx 1$ axis.

IV. Diurnal Variations

It is of interest to compare the diurnal variations observed at the several longitudes and at the several particle energies. The mean flux for the three available longitudes is presented in Fig. 17, 18, 19 as a function of local time. As had been found previously (Ref. 11), the diurnal variation is larger at the higher electron energies. There does not seem to be any significant systematic change of the diurnal variation with longitude.

TABLE II
 COMPARISON OF ATS-6 DATA AND AE-4 MODEL
 MEAN FLUX ($\text{cm}^{-2}\text{sec}^{-1}$)

Energy	ATS-6			AE-4	
	$94^{\circ}\text{W}, \lambda_M \approx 11^{\circ}$	$35^{\circ}\text{E}, \lambda_M \approx 0^{\circ}$	$140^{\circ}\text{W}, \lambda_M \approx 0^{\circ}$		
	Day 166, 74-Day 140, 75	Day 180, 75-Day 214, 76	Day 137, 76-Day 210, 76	Day 330, 76-Day 120, 77	
$> 140 \text{ keV}$	5.35×10^6	5.29×10^6	4.84×10^6	4.16×10^6	1.66×10^7 ($> 150 \text{ keV}$)
$> 700 \text{ keV}$	5.01×10^5	5.50×10^5	4.17×10^5	2.45×10^5	1.76×10^6

V. Effects of the Interplanetary Medium on Energetic Electrons

We had earlier discovered (Ref. 14) that the flux level of the energetic electrons at the synchronous orbit - and therefore presumably the flux of energetic electrons in the entire outer magnetosphere - was modulated by the passage of the sector boundaries of the interplanetary magnetic field (IMF) past the earth. Briefly, we found that the flux levels were higher during northern hemisphere fall when the earth was immersed in a positive sector than during the passage of a negative sector of the interplanetary magnetic field. Conversely, in the spring, negative sectors served to generate higher energetic electron fluxes. This finding was found to be in agreement with the picture of solar wind-magnetosphere interaction proposed by Russell and McPherron (Ref. 17).

The findings described above were based on a very limited set of data. In the past year we have attempted to confirm and extend our conclusions using the more than 2½ years of data presently available. The relevant points can be seen by examining Figures 2-5, where we have plotted the daily averages of the energetic electron fluxes, together with the sector structure of the interplanetary field (see the caption of Figure 2 for explanation of IMF data presentation). It can be seen from these figures that the sector structure of the interplanetary field provides the dominant modulation of electron fluxes. Our conclusion that higher fluxes result in the fall from + sectors than from - sectors (and that the converse holds true in the spring) can be verified by inspection of these figures. We are now in the process of trying to assess more quantitatively the relationship between the vector of the interplanetary field and the velocity of the solar wind and the generation of energetic particles in the magnetosphere.

This study, if successful, may lead to techniques for the quantitative prediction of the energetic electron fluxes at the synchronous altitude, using as input solar wind and IMF data. It appears that using data on the local (i.e. near earth) solar wind, radiation fluxes could be predicted several days in advance because of an apparent time lag between changes in interplanetary conditions and the generation by magnetospheric processes of energetic electron fluxes. Should our knowledge of solar physics, i.e. our understanding of the structure and properties of coronal holes and the

solar wind advance sufficiently, then solar data, coupled with an appropriate understanding of interplanetary transport processes, might enable radiation predictions to be made of the order of a week ahead of time.

We mention this potential benefit, because it is clear that in the future, applications spacecraft of many varieties are likely to proliferate in the synchronous orbit (see Refs. 1 and 2, for example), and modest advances in radiation prediction - particularly for manned spaceflight applications, may yield extremely beneficial results.

VI. Future Work

We plan to update and revise this report as additional ATS-6 data are reduced and analyzed. At the time of writing (August 1977) the experiment continues to function well. With luck (and NASA's continued interest) ATS-6 will cover the rising portion of the solar activity cycle and provide unique data in this respect.

In addition, we plan to analyze ATS-1 data, which were acquired simultaneously with ATS-6 during portions of 1974, 1975 and 1976. The comparison between data from spacecraft fixed in longitude (ATS-1) and the ATS-6 which sampled a range of longitude should provide definitive information of the variation of the properties of the electron radiation with longitude at the synchronous orbit.

VII. Acknowledgments

The ATS-6 experiment which yielded the results described in this report was developed with the able assistance of Sam Imamoto and Gloria Roberts. The data reduction efforts were handled by Doretha (Ross) Mayfield. This work was carried out as part of the program of Mission Oriented Investigations and Experimentation supported at The Aerospace Corporation by the USAF Space and Missile System Organization under Contract No. F04701-76-C-0077. Portions of the data reduction efforts were supported by NASA under Contracts NASW-2762, NASW-2879 and NAS5-23788.

- Figure 2. Daily average fluxes for 1974 for the four channels of ATS-6 electron data. The trace at the bottom of each panel gives the sector structure of the interplanetary magnetic field as determined by Svalgaard (Ref. 16). Positive sector days are indicated by the upper line, negative sector days by the lower line. Days when polarity is mixed are indicated by a point falling between the two lines.
- Figure 3. Same as Figure 1, except for 1975. The data for the > 3.9 Mev channel are suspect after Day 140, 1975 and have been deleted.
- Figure 4. Same as Figure 1, except for 1976. The data for the > 3.9 Mev channel are suspect between Day 1 and Day 90 and have been deleted.
- Figure 5. Same as Figure 1, except for 1977. Isolated days of data are indicated by unconnected points.
- Figure 6. Running 27 day average electron fluxes for the four channels of ATS-6 energetic electron data obtained in 1974. Interplanetary magnetic field sector structure is indicated on each panel of data (see Fig. 2 caption for explanation).
- Figure 7. Same as Figure 7, for 1975. $E > 3.9$ Mev data after Day 140 is suspect and have been deleted.
- Figure 8. Same as Figure 7, for 1976. $E > 3.9$ Mev data between Day 1 and Day 90 are suspect and have been deleted.
- Figure 9. Same as Figure 7, for 1977.

- Figure 10. Normalized differential probability $P(F)$ of observing a flux F_x for the four ATS-6 electron channels during the interval Day 165, 1974 to Day 140, 1975 when ATS-6 was located at 94°W . This figure was constructed by sorting the observations into bins 0.1 wide in $\log_{10} F_x$. Data for all local times are included. The electron energies are E1: 140-600 keV, E2 $>$ 700 keV, E3 $>$ 1.55 MeV and E4 $>$ 3.9 MeV. The units of F_x are $\text{cm}^{-2}\text{sec}^{-1}$ for all channels except E1 where the units are $\text{cm}^{-2}\text{sec}^{-1}\text{sr}^{-1}$ instead. The notation "ALL" on the figure indicates that all polarities of the interplanetary magnetic field are included in this analysis. The column U gives the mean of the logarithms of the (hourly average) fluxes during this interval, the column J gives the logarithm of the mean flux and S is the logarithm of the standard deviation from U.
- Figure 11. The data of Figure 10 are presented as integral probabilities $P(F > F_x)$ of observing a flux greater than F_x during the Day 165, 1974 to Day 140, 1975 time interval. All other comments apply.
- Figure 12. Same as Figure 10, except the time interval is Day 180, 1975 to Day 214, 1976 where ATS-6 was located at 35°E . The E4 curve contains data from the interval 90, 76 to 214, 76.
- Figure 13. The data of Figure 12 are presented as integral probabilities of observing a flux greater than F_x during the Day 180, 1975 to Day 214, 1976 time interval. All other comments apply.
- Figure 14. Same as Figure 10, except the time interval is Day 330, 1976 to Day 120, 1977 where ATS-6 was located at 140°W . The prominent peak in E4 near an apparent flux of $\approx 10 \text{ cm}^{-2}\text{sec}^{-1}$ is due to the galactic cosmic ray background (see Appendix A) because the energetic electron flux was very low during this time period -see Figures 4, 5, and 8, 9.
- Figure 15. The data of Figure 14 are presented as integral probabilities of observing a flux greater than F_x during the Day 330, 1976 to Day 120, 1977 time interval. All other comments apply. Note that for a flux of $\approx 15 \text{ cm}^{-2}\text{sec}^{-1}$ in the E4 channel all "electrons" are really galactic cosmic rays or their products.

- Figure 16. Electron energy spectra constructed using the average fluxes for each time interval indicated. The fluxes measured in the 140-600 keV directional channel have been multiplied by 4π to obtain a measure of the omnidirectional flux in this energy interval. The $E_e > 3.9$ Mev point associated with the Day 180, 1975 to Day 214, 1976 curve was obtained using data from the Day 92, 1976 to Day 210, 1976 interval.
- Figure 17. Diurnal variation of the average electron flux observed during the time interval Day 165, 1974 - Day 140, 1975 when ATS-6 was located at 94°W .
- Figure 18. Same as Figure 17, except that the time interval is Day 180, 1975 to Day 214, 1976 when ATS-6 was located at 35°E . The E4 channel is not shown.
- Figure 19. Same as Figure 17, except that the time interval is Day 330, 1976 to Day 120, 1977. ATS-6 was at 140°W at this time.

Appendix A: A Description of Instrument Response

A full description of the ATS-6 Aerospace Corporation experiment has been presented in Ref. 13. Here we summarize, for ready reference, those salient features of the instrument response which may be of interest or assistance in interpretation of the results presented in earlier portions of this report.

Instrument Description

Figure A-1 shows a schematic block diagram of the detector/electronic system. The electron channels, E1, E2, E3, E4 are derived from Sensors 1-4 respectively. Figure A-2 shows the experiment.

Electron Detection

The responses of the electron channels are illustrated in Figures A-3 and A-4 respectively. These data, integrated over the angular acceptance angles of each detector give the average detector geometric factor as a function of energy. It has proven convenient to integrate these energy dependent geometric factors over various (assumed) shapes of the incident electron spectrum and finding a threshold (or set of thresholds for the E1 channel) which minimizes the variation of the geometric factor with spectral shape. The results are presented in Table A-1. The ϵ G factors given in this table were used to convert from counts to flux above the indicated thresholds (or, for E1, in the indicated energy interval).

Proton Contamination

Proton channels which measure trapped and solar proton fluxes are also associated with each detector. In principle, the proton data can be used to correct for any proton contamination of the electron data. In practice, we found that during the 1974-1977 interval, solar proton activity was very low and no systematic correction was required; instead, days of data where some solar proton contamination (primarily of the E3, E4 channels) was suspected were rejected from the analysis. The sporadic fluxes of low energy (several Mev) trapped protons which we occasionally observed did not have any effect on the electron channels. Galactic cosmic rays and the products generated by their interaction with the spacecraft gave

rise to a significant background in the E4 channel. This background has a diurnal signature characteristic of cosmic rays (i.e. a maximum near local midnight and a minimum near local noon). During time periods when the trapped electron flux was low, for example the late 1976 - early 1977 time period, this background can be clearly visible in the E4 data (see Fig. 5) as an apparent flux of $\approx 10 \text{ cm}^{-2}\text{sec}^{-1}$. The true flux is more likely $\approx 5 \text{ cm}^{-2}\text{sec}^{-1}$ because the geometric factor of the E4 channel for these very energetic, minimum ionizing particles is a factor of two larger than quoted in Table A-1. This background has not been subtracted from our results; although of galactic origin, the radiation masquerading as "energetic electrons" is always present at the synchronous orbit, is practically indistinguishable from energetic electrons, and may be of some practical consequence as an ever-present background.

Bremsstrahlung Effects

During our calibrations, the bremsstrahlung efficiencies of the E2, E3, E4 channels were measured. Upper limits for the efficiencies were determined; those upper limits fall well below 10^{-4} relative to the direct detection of electrons. In all cases, we find that the galactic cosmic ray background exceeds that which might be generated by bremsstrahlung.

Accuracy of Results

The dominant source of error in this experiment arises because of the uncertainty, estimated to be $\approx 20\%$, in the geometric factors. All other experimental sources of error are minimal. While, under some circumstances, counting statistics may contribute additional uncertainty, in this paper we are dealing with long term flux averages which effectively eliminate counting statistics on an error source. It is important to reiterate that our measurements deal with a high variable phenomenon characterized by significant deviations from the mean. Comparisons of our results with those of others need to take this into account and also recognize that important long term effects (related to the 11 year solar cycle) in the structure of the radiation belts exist.

TABLE-A-1
Omnidirectional Geometric Factors

Channel	Passband or Threshold (Mev)	ϵG
E1	0.140-0.600	0.115 cm ² sr
E2	0.700	0.00349 cm ²
E3	1.55	0.0176 cm ²
E4	3.90	0.0688 cm ²

Appendix Figure Captions

- Figure A-1 Schematic block diagram of detector/electronic system.
- Figure A-2. Overall view of the energetic particle spectrometer on ATS-6. Directional detectors (E1 channel) are housed inside the cylindrical collimator structure in the foreground.
- Figure A-3. Efficiency of detection of electrons in the E1 channel. This channel has a nominal energy sensitivity of 140-600 keV. Sensitivity of this channel below the nominal electronic threshold is associated with the finite noise of the detector.
- Figure A-4. Effective area of the E2, E3 and E4 electron channels as a function of electron energy. This effective area, when integrated over the angular response of the detector, yields the omnidirectional geometric factor. Bremsstrahlung efficiencies fall well below lower limits of this figure.
