Table 61. Summary of percentage changes in urine constituents when expressed as quantity excreted per unit quantity of creatinine excreted on the days of continuous recumbency indicated. The percentages statistically significantly different from the base value of 100% ($P < 0.05$) are indicated by an asterisk.

Constituent	Day 2	Day 6	Day 12-13	Day 19
Osmotic Activity	103.6	100.3	92.5	70.7
Chloride	117.6*	91.9	93.4	53.6
Sodium	110.3	92.9	95.7	65.8
Potassium	96.9	104.3	96.3	59.3
Magnesium	95.8	79.1	76.0	108.8
Calcium	110.5	95.8	115.5	120.8
Phosphate	78.7*	103.1	96.7	91.1
Total Nitrogen	89.7*	94.2	110.8	106.3
Ammonia	98.4	81.7	97.7	125.1*
Urea	87.2*	100.4	126.2	144.4
Creatine	97.1	283.9	98.1	208.8
Hydroxyproline	98.0	74.3	114.1	128.2
Glucose	88.4	78.2	130.8	118.2
Citrate	97.0	110.9	101.2	102.9
17-OH Corticosteroids	121.0	90.4	107.8	87.7
Epinephrine	93.0	59.2	56.0	45.7
Norepinephrine	97.8	76.3	71.2	83.8

IN VIVO MEASUREMENT OF HUMAN BODY COMPOSITION

During the summer of 1974 investigators from this laboratory collaborated in a bed-rest study conducted in the Human Research Facility of the NASA Ames Research Center. Dr. Harold Sandler, Chief, Biomedical Research Division, NASA Ames Research Center, was the Principal Investigator for the entire study, and Dr. Charles M. Winget, Human Studies Branch, served as the Project Manager.

The study was designed to examine the time course of a number of physiological changes that occur during the first 21 days of continuous bed rest, and involved a total of 14 normal men in the age range of 25 to 36 years. The men were divided into 4 groups, Groups A, B, C, and D, of 3 or 4 men each, and were tested on a staggered schedule in the Human Research Facility.

In each instance, the members of a subject group entered the Human Research Facility and remained ambulatory for 8 days before the bed-rest period was begun, in order to provide base-line physiological information. The 3 men of Group A were scheduled for 3 days of continuous recumbency, the 4 men of Group B for 7 days, the 3 men of Group C for 14 days, and the 4 men of Group D for 21 days.

The schedule was arranged in such a way that our laboratory (UCB) personnel performed base-line tests on all subjects 1 to 2 days before the start of their bed-rest period. The UCB measurements on Group A were repeated on Day 2 of bed rest, and on Group B they were repeated on Day 2 and Day 6. On Group C, the UCB measurements were repeated in 2 of the subjects on Day 6 of bed rest, and in 1 subject on Day 12 of bed rest. On Group D, the UCB measurements were repeated in 3 of the subjects on Day 13 and Day 19 of bed rest. The schedule followed for the UCB measurements is summarized in Table 1.

Table 2 identifies the subjects comprising each of the 4 groups tested, and gives their vital statistics. Table 3 rearranges this same information in terms of the data groupings examined to ascertain the effects of different periods of bed rest in the subjects. It will be noted that subjects of Groups B and C appear twice in the listings because of the identicity of the duration of continuous bed rest when the measurements were made, as provided by the schedule shown in Table 1. It will also be noted that the groupings in Table 3 eliminate, as appropriate, the subjects who were studied early in the experiment, but who dropped out during the course of the experiments. These groupings permitted statistical evaluation by paired t-test of differences seen between the base values and each period of continuous bed rest indicated.

The measurements made by UCB personnel fell into 3 categories:

- (1) *in vivo* body compartment measurements made at the Human Research Facility;
- (2) biochemical analyses for various blood constituent levels made on samples taken to UCB; (3) determination of a number of urinary constituent excretion rates from 24-hr urine collections made at the Human Research Facility and analyzed at UCB. Results from the first 2 classes of measurements have been reported earlier in Semi-Annual Status Report No. 5. The results of the urine analyses are reported herein.

The urine collections were started at approximately 0700 on the morning of the UCB test days shown in Table 1, and continued until approximately 0700 of the next day. Collection times were noted for each subject, and the urine was preserved by the addition of thymol crystals to the collection. On delivery to UCB, the volume, specific gravity, osmolarity, and pH of the collection were measured, and aliquot samples were frozen for subsequent

additional analyses. The samples were analyzed for concentration of chloride, sodium, potassium, magnesium, calcium, phosphate, total nitrogen, ammonia, urea, creatinine, creatine, hydroxyproline, glucose, citrate, 17-hydroxycorticosteroids, epinephrine, and norepinephrine, and 24-hr excretion rates were computed for each constituent.

All the urine analysis data obtained by our laboratory from the 1974 NASA/Ames Time Course Bed-Rest Study, tabulated according to the group and date arrangements shown in Tables 1 and 2, are listed for each constituent measured in Tables 4 to 26. The same data, appropriately selected and arranged as in Table 3 for paired comparison, are given in Tables 27 to 34. Also shown in the latter tables are the mean, standard deviation, and standard error for each parameter base value before bed rest and value on the day of bed rest indicated. The absolute difference between the base mean and the bed-rest mean, the percentage of the base mean represented by the bed-rest mean, and the probability by paired t-test that the base mean and bed-rest mean are not statistically distinguishable are given for each constituent at the bottom of Tables 27 to 34.

Table 35 summarizes the percentage changes for each urine constituent examined during the course of the 1974 NASA/Ames Time Course Bed-Rest Study. The values shown represent the bed-rest mean values as a percentage of the base mean value for the particular subject group involved, and were taken from Tables 27 to 34. The statistically significant differences are indicated.

Examination of Table 18, however, which gives the 24-hr urine creatinine excretion rates, shows large variability both among the subjects and for the same subject in many cases. For example, the mean base value for all 14 subjects is 17.1 mmol/24 hr with a standard deviation of \pm 4.0 mmol/24 hr.

This yields a coefficient of variation of 23.4%, which is much greater than would be expected normally.

A possible reason for the exceptionally high variance in urinary creatinine excretion rate is inaccuracy in making the 24-hr urine collection. Therefore, the excretion of the other urinary constituents was computed as unit excreted per unit of creatinine measured in each sample. The results are given in Tables 36 to 52 for all the urine samples analyzed, and these data arranged for paired comparison by t-test are repeated in Tables 53 to 60 as before.

Table 61 summarizes the percentage change of each constituent, based on the creatinine concentration of each sample, as a function of days of continuous recumbency, and probably represents a more valid comparison of the subjects than does Table 35. Therefore, comment will be restricted to the data of Table 61.

The striking generalization which emerges on inspection of Table 61 is the lack of discernible effect of the bed-rest conditions of this experiment on urinary constituent excretion rates. With one exception, the only statistically significant variations observed were a small increase in chloride excreted per unit of creatinine excreted, and decreases in phosphate, total nitrogen and urea excretion on Day 2. The change in chloride excretion was probably not of physiological significance, and the change in the other constituent excretion rates is readily attributable to variations in dietary intake. The only other statistically significant difference noted was a small increase in ammonia excretion on Day 19 of bed rest. However, here again the most likely conclusion is that this was not of physiological significance.

There is suggestion in the data that calcium and creatine excretion may have been elevated during bed rest, and that epinephrine and norepinephrine

excretion may have been depressed. However, this impression could not be confirmed statistically, even though such changes might have been expected. In contrast, there was no indication of an expected increase in either phosphate or 17-hydroxycorticosteroid excretion, which also might have been expected.

A possible explanation for the essentially negative findings from the urine analyses of this study may lie in the combination of the high level of variance associated with the sample collections and the small number of subjects involved in the longer bed-rest periods. It is technically difficult, yet essential, to make rigorously quantitative urine collections from human subjects if excretion rates of constituents are to be assessed accurately. The variance in results is further increased substantially unless the dietary intake is carefully standardized. Finally, the use of only 3 or 4 subjects is marginal at best for drawing statistically valid conclusions.

The results of the blood analyses from this study reported previously in Semi-Annual Status Report No. 5 indicate clearly that major metabolic adjustments occur during prolonged bed rest. It would be worthwhile to repeat the measurement of urinary metabolite excretion rates under more carefully controlled experimental conditions.
