ABSTRACT

Presented herein are results of heat transfer tests of a 147B configuration orbiter model (50-0) conducted in the NASA Langley Research Center Freon Tunnel (LRC/CF₄). These tests were conducted at a nominal Mach number of 6, and at Reynolds numbers of 0.3 and 0.5×10^6 per foot. The objectives of the tests were to determine the effects of the low freon specific heat ratio, γ , on the heating distributions and to determine the impingement of the orbiter bow shock on the wing.

The data presented include thin skin heat transfer data (tabulated data and plotted data).

INTRODUCTION

The use of air as a test media to simulate hypersonic flight is for most conditions limited due to the inability to provide air of sufficiently high temperature. In particular, when attempting to simulate hypersonic flight of large vehicles in planetary atmospheres, the chemical dissociation in the high-temperature gas behind the shock wave creates large density ratios which cannot be simulated. It has been found that these large density ratios can be experimentally obtained, without chemical dissociation, in a media of relatively low temperature and low ratio of specific heats. The use of freon in a wind tunnel to obtain large shock density ratios and thus simulate real gas effects for hypersonic flight is described in Reference (1).

Thin-skin heat transfer tests of a scaled Space Shuttle orbiter (Test OH45, Model 50-0) were conducted in a freon tunnel (described in Reference (1)) to obtain a more accurate simulation of atmospheric entry flight conditions. The purpose of this report is to present the results of these tests and how they were obtained.

REMARKS

Seventy-seven thermocouples were used to obtain thin-skin heat transfer data at the test conditions shown in Table I. The run schedule shown in Table II lists the sixteen good heat transfer runs and three good oil flow runs obtained during the test.

In addition to thin-skin heat transfer data, oil flow data was obtained during Test OH45. Three oil flow runs were made at the end of the test using the 50-0 model, without its instrumentation hooked-up, and a -139A modified orbiter model. The -139A modified orbiter was configuration #4 of the 46-0 thermal paint model. It was non-instrumented. Polaroid photographs were taken of the oil flow patterns after each run.

Since the oil flow runs were not pertinent to the purpose of Test OH45, they will not be discussed throughout this report except as follows:

1. The test conditions are presented in Table I.
2. The run conditions are presented in Table II.
3. The -139A modified orbiter nomenclature are presented in "Configurations Investigated", and the dimensional data are presented in Table IV. Reference (2) gives a description of the -139A modified orbiter.
4. The oil flow model coating is described in "Test OH45 Test Procedures".

The model 50-0 instrumentation did not present any problems during the test; however, two faulty thermocouples, #8 and #14, were found during model installation, and one thermocouple, #54, had its polarity reversed. They were not fixed for the test.

CONFIGURATIONS INVESTIGATED

Model 50-0 is a 0.006-scale representation of the Space Shuttle orbiter. It is a full-span cast stainless steel (17-4 PH) model of orbiter lines -147B. It has thin skin inserts on the bottom centerline, top centerline, windshield area, left fuselage side, and left wing lower surface. Elevon, rudder, and body flap deflections were not simulated.

Nomenclature for model 50-0 is as follows:

B ₂₂	Fuselage (-147B Lines)
C ₇	Canopy
F ₅	Body Flap
M ₄	OMS Pod
V ₇	Vertical Tail
W ₁₁₁	Wing

Table III presents the model 50-0 dimensional data.

Nomenclature for the -139A modified orbiter (46-0, #4 model) is as follows:

B ₁₇	Fuselage (-139A Lines).
C ₇	Canopy
F ₅	Body Flap
M ₄	OMS Pod
V ₇	Vertical Tail
W ₁₀₄ (modified)	Wing

Table IV presents the -139A modified orbiter dimensional data.

INSTRUMENTATION

Instrumentation on model 50-0 consisted of seventy-seven iron-constantan thermocouples, with Kapton insulation, spot welded to the thin-skin inserts. The location of each thermocouple and the skin thickness at each location are given in Table V. Figure 1 illustrates the thermocouple locations.

Tunnel parameter instrumentation consisted of two pressure transducers and one thermocouple. The transducers measured tunnel stagnation pressure and the nozzle exit pitot pressure. The thermocouple measured tunnel stagnation temperature.

All model 50-0 thermocouples could not be recorded simultaneously. Depending on their location, they were divided into two groups for recording during separate runs. The two thermocouple groups are shown in Table VI.

FACILITY DESCRIPTION

Test OH45 was conducted in the NASA LRC Freon Tunnel. Freon 14 was the test medium. The tunnel has an open-jet test section with a core about fifteen inches in diameter. It operates at a nominal Mach number of 6 and over a nominal Reynolds number range of $0.1 \text{ to } 0.7 \times 10^6$ per foot.

Reference (1) shows operating characteristics for the NASA LRC Freon Tunnel.

TEST PROCEDURES

The model was sting mounted to a 30 degree offset sting adapter used for obtaining 25, 30, and 35 degree angles of attack. The adapter attached to the model support strut. Thermocouple leads were routed through the offset sting adapter and then taped externally to the support strut. Figures 2a, b, and c show model 50-0 installed in the LRC/CF₄ Tunnel.

Model 50-0 was programmed automatically to inject and stay on the tunnel centerline for three seconds to record the thin-skin heat transfer data.

Angles of attack (α) and angle of sideslip (β) were obtained by simultaneously pitching and rolling the model at the offset sting adapter according to the following equations:

$$\alpha = \tan^{-1} (\tan \alpha_s \cos \phi)$$

$$\beta = \sin^{-1} (\sin \alpha_s \sin \phi)$$

where α_s is the pitch angle of the strut sector, and ϕ is the model roll angle.

Changing the thermocouple recording between group A and group B required a simple switch of instrumentation patchboards; therefore groups A and B were run "back-to-back" for a given set of model and test conditions. Thus all thermocouples were recorded on tape through the Data Acquisition System (DAS) for given model and test conditions. For each run, thermocouples not recorded on the DAS were recorded on oscillograph traces as back-up data.

TEST PROCEDURES (Concluded)

One colored Schlieren per run was taken during acquisition of the thin-skin heat transfer data. Schlieren pictures of the model planform were obtained by rolling the model and the bent sting adapter 90 degrees. Only wing thermocouples were recorded during these runs which, except for tunnel flow irregularities, were repeats of the runs at 0 degrees roll.

For the oil flow runs, the model was first coated with 125 cs viscosity oil. Then a lamp black and 50 cs viscosity oil mixture was splattered on the model with a stiff bristle brush. For the -139A modified orbiter, white lead was mixed with the lamp black to provide contrast.

DATA REDUCTION

The thermocouple heat transfer data was reduced using the one-dimensional thin wall equation:

$$\dot{q} = Wcb \frac{dT_w}{dt}, \text{ BTU}/\text{ft}^2(\text{sec}) \quad (1)$$

where the symbols are defined in the nomenclature section. Stainless steel 17-4 PH was used in the fabrication of instrumented thin skin sections. A curve of specific heat, c , as a function of temperature is presented in figure 3. All thermocouples were iron-constantan. The material thickness for each thermocouple location is presented in Table V. The density, W , of the model material is given below:

MATERIAL	CONDITION	W(Density)	
		lbm/in ³	lbm/ft ³
17-4 PH	H 1150	0.284	491

Theoretical stagnation point heat transfer rate was calculated using Fay and Riddell's equation:

$$\dot{q}_{ot} = 0.94 (\rho_w \mu_w)^{.5} (\rho'_o \mu'_o / \rho_w \mu_w)^{.4} (H_o - H_w) (du/dx)^{.5} \quad (2)$$

$$\text{where: } \mu_w = \frac{0.0232 \times 10^{-6} T^{.5}}{1 + (220/T)}$$

$$\text{and } \frac{du}{dx} = (1/rs) [2RT(1-P_\infty/P_o)]^{.5}$$

Computed local heat transfer coefficient for each thermocouple is:

DATA REDUCTION (Continued)

$$h_{\text{local}} = \frac{\dot{q}}{r_{T_0} - T_w} \quad (3)$$

at $r = 1.0, .9, .85$

Computed ratio of local heat transfer coefficient to reference heat transfer coefficient is:

$$\frac{h_{\text{local}}}{h_{\text{ref}}} \quad (4)$$

$$\text{where } h_{\text{ref}} = \frac{\dot{q}_{\text{ot}}}{r_{T_0} - T_w}, \quad (r = 1.0)$$

The ratio of local heat transfer coefficient to reference heat transfer coefficient was computed at adiabatic wall temperature ratios of $r = .85, .90$, and 1.0 .

The Test OH45 tabulated data is in the following format:

<u>Symbol</u>	<u>Description</u>
<u>Tunnel data</u>	
ALPHA	Model angle of attack
MACH	Tunnel freestream Mach number
PO	Tunnel freestream static pressure (psia)
TO	Tunnel stagnation temperature ($^{\circ}$ R)
HO	Tunnel stagnation enthalpy (BTU/lb)

DATA REDUCTION (Concluded)

<u>Symbol</u>	<u>Description</u>
<u>Thermocouple Data</u>	
Geometry	Thermocouple location
H/HREF	Ratio of local to stagnation point heat transfer coefficients for recovery factors of 0.85, 0.9 and 1.0

MODEL COMPONENT: WING-W₁₀₄ - New lightweight orbiter (modified)

GENERAL DESCRIPTION: Orbiter wing for Model 46-4. NOTE: Dihedral angle is defined at the lower surface of the wing at the 75.33% element line projected into a plane perpendicular to the FRL. Underside of the wing-body is smoothly faired to a saucer shape.
