## PREFACE

The purpose of this contract is to provide data processing and analysis in support of two GSFC programs: tornado detection by radio frequency techniques and short pulse radar measurements of ocean waves. The first quarter's effort was concentrated primarily on the former program - specifically on the strip chart recording of the tornado detection raw data and preliminary analyses of the data. The next quarter's work will concentrate on digitizing, displaying, and analyzing selected data portions of interest based on the strip chart recordings.

## I. Introduction

The tornado data analog tapes are 14 track tapes containing the information shown in table I. The recordings cover 4 HF and VHF frequency bands with vertical and horizontal polarizations and with linear and logarithmic scales. In addition the outputs from 2 different lightning stroke detectors are recorded. Over 50 tapes have been currently generated by another contractor to GSFC. Recording speeds of 30 ips and 60 ips were used.

Techno-Sciences has provided analog strip charts of all available tapes on GSFC supplied equipment in coordination with the contract technical officer. A complete $\log$ of this proressing is included with this report in table II. Because the st:ip chart recorder has only 7 useable channels, only half of the tracks on each tape were actually processed in most cases. The other tracke could have been processed by making a second pass through each tape. However, it was found that 7 tracks had most of the useful information anyway. In particular, the logarithmic scale and timing tracks were found to be of 1 imited usefulness.

Current work is concentrating on digitizing selected analog tape portions for detailed analysis and display.

TORNADO ANALOG TAPE TRACK ASSIGNMENTS

| Track | Mode | Assignment |

## II. Analog Strip Chart Kecordings

Table II is a processing $\log$ which sumnarizes the useful analog strip chart recording results by Techno-Sciences on GSFC supplied equipment. In addition to these results, other recordings were made but not kept because of various equipment problems which resulted in invalid or useless data displays. Many of the tapes were found to be very quiet, containing indiscernable signals or noise of a "white" rather than of the desired impulsive nature characterizing lightning discharges. Others, however contained considerable amounts of the desired impulsive noise across all frequencies. A short segment of one of these displays appears in figure "one".

The data was recorded at a real time (one-sided) bandwidth of 300 khz . As shown in Appendix B, the strip chart recording technique used is physically limited to be able to show only about $20 \%$ of the actual bandwidth. Even this could only be achieved at 1-7/8 ips playback speeds and $50 \mathrm{~cm} / \mathrm{sec}$ strip chart speeds, which would generate unacce'ptably large amounts of output Hence, the strip chart recordings can only be viewed as a "quick look" tool. Selected portions of the data must be digitized for processing and display.

As shown in Appendix $C$, the amount of digital data generated from even a short segment of analog tape is very large. Hence, the segments must be carefully selected. The addition of a timing track may be necessary in this regard as an aid in registration at some point.

## III. Data Digitization

One of the more interesting tapes (8/26/75 - \#3) was selected for digitization and preliminary analysis and display. A request was made to GSFC for its digitization in September. However, as a result of the inavailability of equipmeni and appropriate software, the digitization has nct been accomplished to date. Therefore an alternate digitization plan is being pursued.

The Ampex PR-2200 tape recorder used in the Georgia Institute of Technology research instrumentation is temporarily available to playback selected tapes for digitization. This recorder is being used as an input to the A/D hardware developed at GSFC for data compression. Computer programs are being written by Techno-Sciences to ingest the sampled data to core memory. Initial output will be to digital tape which has a basic (burst) limitation of 20,000 bytes per second ( 10 or 20 thousand samples per second dependent on quantization). Next programs will be developed to support rates to 100,000 bytes per second for transfer to disk storage.
IV. Plans for the Next Quarter

Digitization will be accomplished as discussed in section III. As the digital data becomes available, analysis efforts will begin. The first analytical effort will be the isolation, display and analysis of individual lightning pulses. Time and frequency display will be accomplished using Fourier transforms. The time signal will be compared with earlior published results. The transformed data will be investigated to determine actual bandwidth utilization. If the lightning stroke generates true impulses, the frequency content should be approximately flat to 300 khz and an individual pulse in time should approximate the impulse response of the system filter. Burst counts, intennulse statistics and amplitude probability distributions will be generated as an initial approach to determining a statistical model for lightning discharges. If sufficient data is available, tornado and non-tornado statistics will be segregated and contrasted for a possibie tornado detection methadology.

## Appendix A

The Sampling Theorem

Suppose that $x(t)$ is an analog waveform containing frequencies from zero up to some maximum value $B h_{z}$. The sampling theorem states that you must sample at a rate of at least $2 B$ samples per second to reconstruct the waveform without error. The sampling rate, $2 B$, is called the Nyquist rate. To see the necessity for this, consider the simple co-sinusoids $\cos 2(B-\varepsilon) t-a n d \cos 2(B+\varepsilon) t$ for any $\varepsilon$. The nth sample at the sampling rate $2 B$ per second of each is

$$
\begin{gathered}
\cos 2 \pi(B-\varepsilon) \frac{n}{2 B}=(\cos n \pi) \cos \frac{n \pi \varepsilon}{B}+(\sin n \pi) \sin \frac{n \pi \varepsilon}{B} \\
=(-1)^{n} \cos \frac{n \pi \varepsilon}{B}
\end{gathered}
$$

and $\cos 2 \pi(B+\varepsilon) \frac{n}{2 B}=(\cos n \pi) \cos \frac{n \pi \varepsilon}{B}-(\sin n \pi) \sin \frac{n \pi \varepsilon}{B}$

$$
=(-1)^{n} \quad \cos \frac{n \cdot \pi \varepsilon}{B} .
$$

It is clear that there is no way of distinguishing between the two waveforms based upon the sample values at the rate $2 B$. The characteristic problem of confusing two such waveforms due to undersampling is called aliasing or folding and can be avoided only by sampling fast enough or by filtering (with concurrent loss of high frequency content) to remove all frequencies higher than $1 / 2$ the sampling rate.

Conversely it can be intuitively justified that sampling at twice the highest frequency present is sufficient to reconstruct the

Appendix A

the waveform by arguing trat the 2 samples per cycle can be used to find the 2 degrees of freedom in a sinusoid - the amplitude and the phase.

Quantitative proofs of the sampling theorem can be found in many textbooks on linear systems.

## Appendix B

## Strip Chart Recorder Display Limitations

The Varian strip chart recorder used for the processing of the analog tape recordings under this contract is limi:ed in usefulness by sampling theorem considerations presented in Appendix A. The plotting density of the strip chart recorder is 200 points per inch, which by the sampling theorem allows for a maximum frequency resolution o. a waveform of 100 cycles per inch. The maximum strip chart speed is $50 \mathrm{~cm} / \mathrm{sec}$ or approximately 20 inches $/ \mathrm{sec}$. Thus the maximum frequency content of a signal which can be resolved is approximately 2000 hz .

At the recorded speed, the anlog tapes have frequencies up to 300 khz . The maximum record speed used was 60 ips . At a minimum playback speed of 1-7/8 ips, the highest frequency present is then $300 / 32 \approx 10 \mathrm{khz}$ or 5 times the strip chart recorder's frequency resolving capability.

Thus digital methods must be used to accurately represent and display the anaiog tape data. From the preceding considerations it is seen that a minimum sampling rate of 20,000 samples per second must be used. Higher sampling rates are desirable to avoid analog tape flutter/wow problems at 1-7,8 ips by running higher playback (and hence higher sampling) speeds.

## Appendix C

## Digital Tape Limitations

Based on the sampling rate considerations presented in Appendices $A$ and $B$, it can be easily shown that great selectivity must be exercized in choosing the data to be digitized for display/ analysis. Each of the 14300 khz analog tape tracks requires 600,000 samples per second in real time or, at a recording speed of $60 \mathrm{ips}, 10,000$ samples per inch of analog tape per channel for a total of 140,000 samples per inch for all channels. Assuming 8 bit samples and continuous recniding (no record gaps), a 2400 ft .800 bpi digital tape can hold only ( $2400 \times 12 \times 800$ )/140,000 $=165$ inches $0^{5}$ analog tape or less than 3 seconds of real time sampled data. Hence the channels chosen for sampling and the actuai segments of time should be carefully chosen for maximum information content.
