FOREWORD

This digital simulation study is a continuation of Contract NAS2-7395 and the previous study report (NASA CR-114739) and was performed under the auspices of the NASA Ames Research Center. The first study concentrated on accurately modeling the communications equipment of relay link and the atmospheric scintillation characteristics of an outer planet. This study optimizes the modulation/demodulation link of the previous study and investigates the impact of various scintillation models. For completeness, this report summarizes the results of the previous report. Both the mean error rate and the acquisition properties of the link are explored. The design of simulated equipment was formulated by the TRW Systems Group under subcontract to McDonnell Douglas Astronautics Company-East. Under both studies magnetic tapes of bit error histories were delivered to the Ames Research Center for evaluation of candidate convolutional code structures.

The author expresses his appreciation for the assistance provided by Mr. T. Grant of ARC who performed the decoding analysis and provided the preliminary decoding results for this report.

DIGITAL SIMULATION OF A COMMUNICATION LINK FOR PIONEER SATURN URANUS ATMOSPHERIC ENTRY PROBE

SUMMARY

A digital simulation study is presented for a candidate modulator/demodulator design in an atmospheric scintillation environment with Doppler, Doppler rate and signal attenuation typical of the conditions of an outer planet atmospheric probe. The simulation results indicate that the mean channel error rate with and without scintillation are similar to theoretical characterizations of the link. In addition the simulation gives information for calculating other channel statistics and generates a quantized symbol stream on magnetic tape from which error correction decoding can be analyzed. Some results from the magnetic tape data analyses are also contained herein.

The receiver and bit synchronizer are modeled in the simulation at the level of hardware component parameters rather than at the loop equation level and individual hardware parameters are identified. The atmospheric scintillation amplitude and phase are modeled independently. Both normal and log normal amplitude processes are studied. In each case the scintillations are low pass filtered.

The receiver performance is given for a range of signal to noise ratios with and without the effects of scintillation. The performance is also reviewed for critical receiver parameter variations.

Part I of this report is the body of the study and is bound. Part II of this report contains the appendices and is unbound.

APPENDIX I

COMPLEX AMPLITUDE NOTATION

Complex amplitude notation is a convenient way to normalize the notation to a reference frequency. The signal waveform is thus

$$x(t) = \mathrm{Re}\{\tilde{x}(t) \exp(j w_0 t)\},$$

where the reference frequency is w_0, and the complex amplitude is

$$\tilde{x}(t) = A \exp(j\theta) = A\cos\theta + j A \sin\theta.$$

Herein, A is the signal amplitude, and θ the signal phase. The conventional notation is apparent by combining,

$$\begin{aligned} x(t) &= \mathrm{Re}\{ A \exp(j\theta) \exp(j w_0 t)\} \\ &= A \cos(w_0 t + \theta). \end{aligned}$$

When multiplying in complex amplitudes

$$z(t) = x(t)\, y(t)$$

or

$$z(t) = \mathrm{Re}\{\tilde{x}(t) \exp(j w_0 t)\}\ \mathrm{Re}\{\tilde{y}(t) \exp(j w_0 t)\}.$$

Using the identity

$$\mathrm{Re}\{\tilde{x}(t)\}\ \mathrm{Re}\{\tilde{y}(t)\} = \frac{1}{2}\mathrm{Re}\{\tilde{x}(t)\, \tilde{y}(t) + \tilde{x}(t)\, \tilde{y}^*(t)\},$$

the star denoting the complex conjugate, we have

$$\begin{aligned} z(t) = \frac{1}{2} \mathrm{Re}\{&\tilde{x}(t)\, \tilde{y}(t) \exp(j (w_0+w_1)t) \\ &+ \tilde{x}(t)\, \tilde{y}^*(t) \exp(j (w_0-w_1)t)\}. \end{aligned}$$

Normally one beats down, so the complex amplitude of the difference frequency term is $\frac{1}{2}\tilde{x}(t)\, \tilde{y}^*(t)$.

When filtering x(t) with h(t) to yield y(t), one normally expresses this as

$$y(t) = \int_{-\infty}^{\infty} x(\tau)\, h(t-\tau) d\tau .$$

In complex amplitude notation

$$\begin{aligned} y(t) &= \int_{-\infty}^{\infty} \mathrm{Re}\{\tilde{x}(t) \exp(j w_0 \tau)\}\ \mathrm{Re}\{\tilde{h}(t-\tau) \exp(j w_1 (t-\tau))\}\, d\tau \\ &= \frac{1}{2} \mathrm{Re}\{\int_{-\infty}^{\infty} \tilde{x}(\tau)\, \tilde{h}(t-\tau) \exp(j(w_0-w_1)\tau) \exp(j w_1 t)\, d\tau \} \\ &+ \frac{1}{2} \mathrm{Re}\{\int_{-\infty}^{\infty} \tilde{x}(\tau)\, \tilde{h}^*(t-\tau) \exp(j(w_0+w_1)\tau) \exp(-j w_1 t) d\tau \}. \end{aligned}$$

Normally, x(t) and h(t) are referenced to the same frequency, so that

$$y(t) = \frac{1}{2}\,\mathrm{Re}\,\{\exp(jwt)\int_{-\infty}^{\infty}\tilde{x}(\tau)\,\hat{h}(t-\tau)\,d\tau\}$$
$$+\frac{1}{2}\,\mathrm{Re}\,\{\exp(-jwt)\int_{-\infty}^{\infty}\tilde{x}(\tau)\,\hat{h}^{*}(t-\tau)\exp(2jwt)\,d\tau\}.$$

When the bandwidths of the signal and the filter are narrow compared to the center frequency, one may neglect the second term, so

$$\tilde{y}(t) = \frac{1}{2}\int_{\infty}^{\infty}\tilde{x}(t)\,\hat{h}(t-\tau)\,d\tau.$$

Finally, when the carrier is zero, to represent baseband signals,

$$\tilde{y}(t) = \int_{-\infty}^{\infty}\tilde{x}(t)\,\hat{h}(t-\tau)\,d\tau.$$

Figure I-1 illustrates the usage of complex amplitudes in the simulation. The input has the signal amplitude M_0 and phase θ_1 plus noise θ_n. This represents the radio frequency, and is beat down by the first mixer to intermediate frequency by straightforward multiplication. After filtering, the extraneous phase is represented by ϕ, with M_f representing the filtered amplitude. The real part of the signal from the phase detector is just the amplitude times the sine of the phase. Similarly the real part of the signal from the coherent amplitude detector is just the negative of the amplitude times the cosine of the phase.

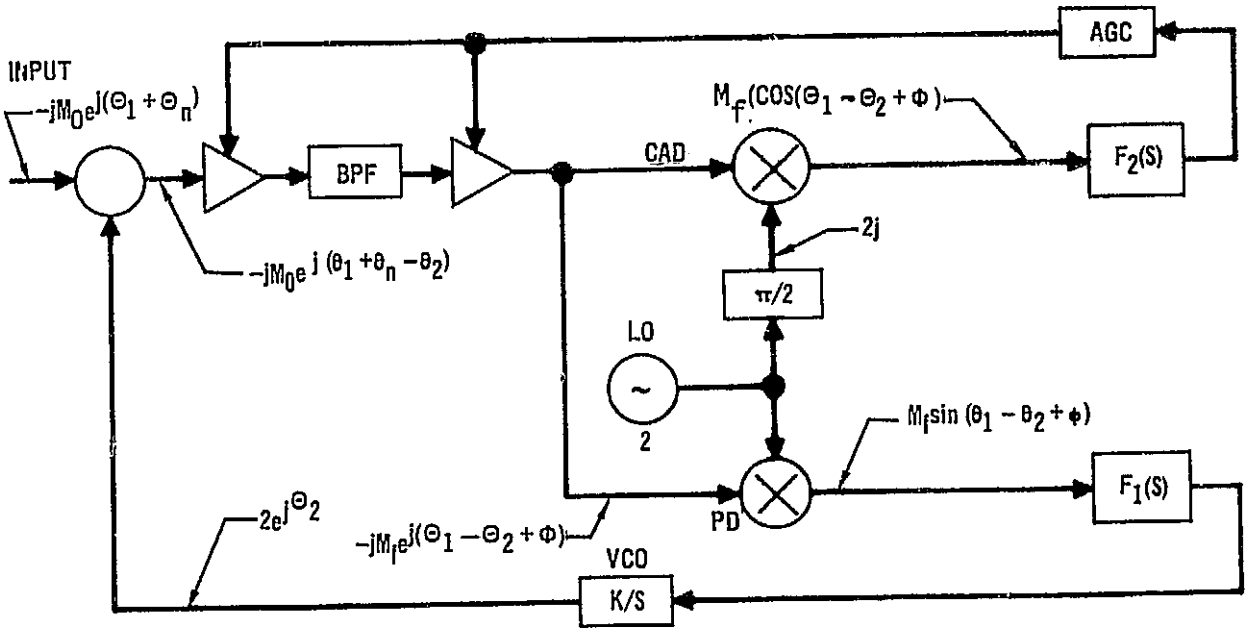

FIGURE I-1 COMPLEX AMPLITUDE USAGE

APPENDIX II

SCINTILLATION FILTERING

ABSTRACT: A tapped delay line filter is presented to represent atmospheric scintillation effects. Data is given to show the aliasing effects of the truncation.

1. Introduction - It is well known that atmospheric turbulence, herein defined as variations in the complex dielectric constant, can cause variation in the amplitude and phase of a received electromagnetic wave. From Tatarski in Ref (A2-1), the power spectral densities of the amplitude and the phase is proportional to the -8/3 power of the frequency above cutoff. This assumes the Kolmogorov form of the turbulent flow. The nature of the fluctuations is different however for amplitude and phase; amplitude fluctuations being dominated by the microscale of the turbulence, and phase fluctuations being dominated by the macroscale of the turbulence.

According to Ames Research Center RFP, the atmospheric effects can be adequately modeled by assuming the amplitude effects of the form

$$A(t) = A_o(1 + x(t))$$

where x(t) is a Gaussian process of zero mean and a root variance of 0.23, low pass filtered with a cutoff of 2.0 Hertz and a $f^{-4/3}$ roll off (note herein the signal is a voltage term). Similarly, the phase effects could be modeled as

$$\theta(t) = \theta_o + \theta_1 t + \theta_2 t^2 + s(t)$$

where s(t) is a Gaussian process of zero mean and a root variance of 0.47, low pass filtered with a cutoff of 0.2 Hertz and a -4/3 roll off.

This note presents the digital form these filters will take.

2. Filter Form - In electrical engineering terms the transfer function of the filter is

$$F(s) = (a/(s+a))^{4/3},$$

where a is the cutoff frequency in radians, and s is $j\omega$.

By simple algebra, the corner is then

$$\omega/a = (2^{3/4} - 1)^{1/2} = .8257074727,$$

or for amplitude $a_x = 15.21891351$

and for phase $a_s = 1.521891351$.

The Laplace transform of the impulse response from Ref (A2-2), is

$$h(t) = [a^{4/3}/\Gamma(4/3)]t^{1/3}\exp(-at),$$

and $$\Gamma(4/3) = .892979511 .$$

For t of zero or infinity of course

$$h(t)\Big|_{\substack{t=0\\ t=\infty}} = 0$$

The function has a maxima at

$$dh(t)/dt \Big|_{t=\frac{1}{3a}} = 0$$

The impulse response is shown in Figure II-1.

3. Z Transform - The quickest computational form of a filter is generally the Z transform (Ref (A2-3)). This is just the Laplace transform with the substitution:

$$z = \exp(sT)$$

Utilizing the simplest interpolator, zero order hold, the discrete transform is

$$(1 - z^{-1})\ Z\ (\tfrac{1}{s}\ F(s)).$$

Since for the case in question

$$\mathcal{L}((a/(s+a))^{4/3}) = a^{4/3}\ \Gamma^{-1}(4/3)\ t^{-1/3}\ e^{-at}\ ,$$

then $$\mathcal{L}(\tfrac{1}{s}F(s)) = \int_0^t a^{4/3}\ \Gamma^{-1}\ (4/3)\ t^{-1/3}\ e^{-at}\ dt = f(t)$$

and by definition

$$Z(\tfrac{1}{s}F(s)) = \sum_{n=0}^{\infty} f(n)z^{-n}$$

Thus

$$Z\left(\frac{1}{s}F(s)\right)= \sum_{n=0}^{\infty} \{a^{4/3} \Gamma^{-1}(4/3) \int_0^t (nT)^{-1/3} e^{-ant} d(nT)\} z^{-n}$$

From Abramowitz and Stegun, Ref (A2-2), the above incomplete gamma function can be written as a Chi-Squared function, or

$$Z\left(\frac{1}{s}F(s)\right) = \sum_{n=0}^{\infty} \{P\left(2ant\middle|\frac{8}{3}\right)\} z^{-n} ,$$

Then the complete transform is

$$(1-z^{-1})\ Z\ \left(\frac{1}{s}F(s)\right)= (1-z^{-1})\{ \sum_{n=0}^{\infty} P\left(2anT\middle|\frac{8}{3}\right) z^{-n}\}$$

$$= P\left(o\middle|\frac{8}{3}\right) z^{-0} + P\left(2aT\middle|\frac{8}{3}\right) z^{-1} + P\left(4aT\middle|\frac{8}{3}\right) z^{-2} + \ldots$$

$$- P\left(2aT\middle|\frac{8}{3}\right) z^{-2} - P\left(4aT\middle|\frac{8}{3}\right) z^{-3} - \ldots$$

$$= 0 + P\left(2aT\middle|\frac{8}{3}\right) z^{-1} + \{P\left(4aT\middle|\frac{8}{3}\right) - P\left(2aT\middle|\frac{8}{3}\right)\} z^{-2}$$

$$+ \{P\left(6aT\middle|\frac{8}{3}\right) - P\left(4aT\middle|\frac{8}{3}\right)\} z^{-3}$$

$$+ \ldots$$

The output ϕ for the input I is then

$$\phi = P\left(2aT\middle|\frac{8}{3}\right) I((n-1)T) + \{P\left(4aT\middle|\frac{8}{3}\right) - P\left(2aT\middle|\frac{8}{3}\right)\} I((n-2)T)$$

$$+ \{P\left(6aT\ \frac{8}{3}\right) - P\left(4aT\middle|\frac{8}{3}\right)\} I((n-3)T)$$

$$+ \ldots$$

Since there appears to be no more concise form, at least to the writer, in this case it appears that the Z transform is no better than a conventional delay line representation. Also, since the Chi-Squared function is evaluated as a series,

$$P(\chi^2|\upsilon) = \Gamma^{-1}(\upsilon/2) \sum_{n=0}^{\infty} \frac{(-1)^n (\chi^2/2)^{\frac{\upsilon}{2}+n}}{n!\ (\frac{\upsilon}{2}+n}$$

the conventional delay line representation appears preferable.

4. Delay Line - There are two design parameters which must be set when representing a filter as a tapped delay line: the tap spacing, T, and the line length, NT. The former describes the "graininess" of the impulse response, and effectively defines the highest frequency represented,

$$f_m = a/(2\gamma) = Kf_b/\gamma$$

Therein $T = \gamma/a$,

f_b is the corner frequency, and for the 4/3 filter

$$K = 3.804728378.$$

The latter describes the fold over aliasing, and effectively defines the lowest frequency (excluding zero) represented,

$$f_L = 1/(NT)$$

As a rule of thumb, the maximum tap contribution, Th(t), should be of the order of 0.1, or

$$T = (0.1)3^{1/3}\,\Gamma(4/3)/(ae^{-1/3})$$

$$\simeq .179740828/a\ .$$

Similarly, the "length" should sum to 0.95 to 0.99, i.e., for the filter in question

$$P(2aNT|\tfrac{8}{3}) = a^{4/3}\,\Gamma^{-1}(4/3)\int_0^{\tau=2aNT}(\tfrac{\tau}{2a})^{1/3}\,e^{\frac{\tau}{2}}\,\frac{1}{2a}\,d\tau,$$

where $\tau = nT = \tau/(2a)$.

The function is plotted in Figure II-2. From the figure it appears that a length 2aNT of 8 to 10 should be adequate, or for 10,

$$NT = (\chi^2 = 10)/2a = 5/a\ .$$

Figures II-3 and II-4 illustrate the amplitude and phase response of three delay lines: T = .1707/a, N = 32; T = .09/a, N = 64 and T = .09/a, N = 128. The magnitude of the error is shown in Figure II-5. The number of taps shown are integer powers of two for convenience in the fast Fourier transform. The rule of thumb filter, T = .17/a, N = 32 appears quite reasonable to an octave beyond the corner, after which the phase response falls off quickly. The second filter, T = .09/a, N = 64 is approximately the same length as the first, but with twice the resolution. This filter holds the correct phase response to two octaves beyond the corner. The third filter, T = .09/a, N = 128 has the same resolution as the second but has twice the length. It shows very little improvement over the second filter.

5. Conclusion - A model for turbulence effects on propagation has been reviewed, and a digital representation designed. The design is summarized in Figure II-6. The magnitude of the amplitude error is less than 1.5% over a decade of frequency beyond the corner.

APPENDIX III

QUANTIZING STRATEGY FOR INPUTS TO VA DECODERS

1. A Viterbi Algorithm (VA) decoder can function with either hard or soft decisions on the input symbols. Typically, the use of 8 level soft decisions on the symbols permits the decoder to operate satisfactorily with ∿2dB less E_b/N_o than if hard decisions are employed. The normally used quantizing strategy results in quantization level spacings of about 0.5 to 0.7 times the standard deviation of the channel noise. This memo explores the derivation of a rationale for choosing the spacings based on the mean and variance of the received symbols. The selected spacings are found to vary between ∿0.58 and 0.64 for means between 1. and 2. sigmas.(3 to 9dB E_b/N_o). These results are equally applicable to a sequential decoder.

2. Theory of VA decoder operation

The VA decoder is a device which chooses the most likely state sequence of the encoded data from the set of possible state sequences. The formal statements of this principle are adequately covered in the published literature. The basic operating technique is to associate a path metric with each state sequence which allows the decoder to select the maximum likelyhood state sequence, based on a set of observations. The path metric, is formally defined as $-\ln \Pr\{\overline{X}|\overline{Z}\}$, where $\overline{X}$ is the set of observations, and $\overline{Z}$ is the state sequence. For a memorly less, binary symetric channel, with Gaussian noise statistics, the path metrics can be simply the sum of the observations, weighted by the expected observation, given the state sequence for the specific path metric. In simpler terms, if $M(= \pm 1)$ is the expected symbol at a given point in time, then $\Gamma_k(i) = \Gamma_k(i-1) - X_i M_i$, where $\Gamma_k(i)$ is the Kth path metric at time i. The state sequence with the smallest path metric is the maximum likelyhood state sequence.

Any two state sequences will have a number of expected symbols which have the same sense, and a number of expected symbols with the opposite sense. If one of these state sequences is the correct state sequence, then $D_{k,j}(i) = \Gamma_k(i) - \Gamma_j(i)$ will be less than zero unless $\sum_i X_i M_i < 0$, where the set, i, includes only those observations where the state sequences differ in interpretation. For the correct path, $E\{X_i M_i\} = n_X$.

Clearly, if X is a normal random variable, then $\Delta_{K,J}(i)$ is also a normal random variable, with a mean $n_\Delta = N n_X$, and $\sigma_\Delta^2 = N\sigma_X^2$, where N is the number of observations contributing to the decision. Then, at any point, an error is committed only if $\Delta_{K,J}(i) > 0$, which would occur with probability $Q(n_X\sqrt{N}/\sigma_X)$ given N pertinent observations. While this cannot be used to directly predict the decoder performance, it can be used to predict the degradation in performance when X is not normally distributed.

3. Quantization

When the symbols are quantized prior to decoding, the X's are no longer normally distributed, since they take only integer values, and finite range, linear quantization results in significant population groups in only a few values of X. Consider the quantization strategy shown in Figure III-1. We have arbitrarily assigned integer values to Z, the quantized estimate of X. If X is a normal random variable with mean η_X and unit variance, then the probability distribution of Z is given by,

$$\Pr\{Z = -7\} = Q(\eta_X+3a)$$
$$\Pr\{Z = -5\} = Q(\eta_X+2a)-Q(\eta_X+3a)$$
$$\Pr\{Z = -3\} = Q(\eta_X+a)-Q(\eta_X+2a)$$

$$\Pr\{Z = +5\} = Q(\eta_X-3a)-Q(\eta_X-2a)$$
$$\Pr\{Z = +7\} = 1-Q(\eta_X-3a)$$

where $Q(X) = \frac{1}{\sigma_X\sqrt{2\pi}} \int_X^\infty \exp-(t-\eta_X)^2/2\sigma_X^2 dt$ and "a" is the quantization level.

It is rather awkward to compute the probability that $\Delta>0$ directly, since the probability distribution of Δ is the result of N convolutions. A more useful approach is to use a Chernov bounds. In this case, we derive these bounds using the Laplace transform of the probability distribution of Z, proceeding as follows:

$$\phi_Z(S) = \sum_{J=1}^{8} \Pr\{Z = 2J-9\}e^{S(2J-9)}$$

Since convolution in normal space is simply a product in transform space, the transform of the probability distribution of Δ is,

$$\phi_\Delta(S) = [\phi_Z(S)]^N$$

Let $\Psi_\Delta(S) = \ln \phi_\Delta(S)$

$$\Psi_\Delta(S) = N\ln[\sum_{J=1}^{8} \Pr\{Z = 2J-9\}e^{S(2J-9)}]$$

$$\Psi_\Delta(S) = \frac{d\Psi_\Delta(S)}{dS} = \frac{N\sum_{J=1}^{8}(2J-9)\Pr\{Z=2J-9\}e^{S(2J-9)}}{\sum_{J=1}^{8}\Pr\{Z=2J-9\}e^{S(2J-9)}}$$

Now, the Chernov bound can be expressed,

$$\Pr\{\Delta>o\} \leq e^{\Psi\Delta(S)}\Big|_{\Psi_\Delta'(S)=0}$$

Thus, we need to solve for the value of S such that,

$$\sum_{J=1}^{8} (2J-9)\Pr\{Z=2J-9\}e^{S(2J-9)} = 0$$

This can be solved numerically, and a value for $\Pr\{\Delta>o\}$ found for any N. Note, however, that

$$\Pr\{\Delta>o\} \leq \left[e^{\Psi_Z(S)}\right]^N \Big|_{\Psi_Z'(S) = 0}$$

Thus, we need only solve for the case N=1, and find the value of "a" which minimized $\Pr\{\Delta>o\}\big|_{N=1}$. For the case $\eta_\chi = 2\sigma_\chi$, which is one of the conditions of interest, the variation of $\Pr\{\Delta>o\}$ with "a" is shown in Figure III-2. We can clearly see that varying "a" over rather broad limits does not change the probability value greatly, however, the optimum is clearly in the vicinity of $a = .62\sigma_\chi$. Figure III-3 illustrates the same information over a wider range of mean to standard deviation.

Now, we note that there is a hazard in using any bound to draw a conclusion of this nature, since varying the parameter "a" may result in variations in the relative tightness of the bound which could be on the order of the variations in the results. Thus, if our conclusions were at significant variance with emperical data, it would be necessary to use a more sophisticated approach to eliminate the uncertainty resulting from the use of bounds. However, the fact that the emperical data is in close agreement with the predicted results, and that the optimum is rather broad, suggests that the increased sophistication is unnecessary.

4. Conclusions

It has been shown that the criteria of minimizing the Chernov bounding value of $\Pr\{\Delta>o\}$ leads to a choice of quantization level of $\sim 0.6\sigma_\chi$, which is halfway between the emperically determined values of 0.5 to $0.7\sigma_\chi$.

FQDPRT	Frequency Doppler rate
FRQDOP	Frequency Doppler
ICLLN	Control variable for scintillation
NACQT	Number of acquisitions, each problem
NRUNS	Number of bits, each problem
PMFILT	Premodulation filter corner frequency
SDAMP	Gain of amplitude scintillation
SDPHA	Gain of phase scintillation
SVRHZ	Sweep slope in Hertz
SWNM	Sweep minimum
SWMX	Sweep maximum
TAU3	AGC time constant
TAU5	Baseband time constant
TAU6	Doppler time constant
TL	Threshold

(All Symbols)

A	Signal voltage
AAMP	Normalized amplitude scintillation
ACOR	Scintillation normalization
ACQ	Number of true acquisitions
ACTH1	A cos (TH1)
AFAL	Number of false acquisitions
ADB	A dropped bit
ADOA	Average number of bits in a dropout
ADOS	Standard deviation of number of bits per dropout
AERR	Printout form of AERRI
AERRI	Errors in a internal of bits
AGC	AGC gain furction
AK	AFC loop gain
AKAGC	AGC gain constant
AKOU	KDATA at acquisition
AKBMIN	Bit synchronizer AK minimum
AKEG	AGC gain offset
ALCOS	List cosine
ALSIN	List sine
AMIN	Minimum A to AFC
AMISS	Number of missed acquisitions
APHA	Normalized phase scintillations
APM	Premodulation filter constant
ARGU	Argument
ASOFT	Soft decision quantization reference
ASOFTI	Soft decision quantization slope
ASTH1	Asin (TH1)
AVEES	Average ES
AVEEV	Average EV
A1, A2	IF filter constants
A5	Baseline connection filter gain
BIF	IF Bandwidth

BL2	2 B_{LO} (AFC)
BL2B	2 B_{LO} (bit synchronizer)
BPER	Bit period
BPM	Premodulation filter constant
BRATE	Bit rate
B1, B2, B3, B4	IF filter constants
CAMP	Complex amplitude into BIF
CBIN1	Hits in SBINS1
CBIN2	Hits in SBINS2
CBIN3	Hits in SBINS3
CBIN4	Hits in SBINS4
CB1	Bit synchronizer Z transform constant 1
CB2	Bit synchronizer Z transform constant 2
CB3	Bit synchronizer Z transform constant 3
CFILT	IF filter output
CORAMP	RC Amplitude normalization
CORPHA	RC Phase normalization
CPM	Premodulation filter constant
CTH1	Cos (TH1)
CTH2	Cos (TH2)
COO	Gaussian polynominal coefficient
C1	AFC filter Z Transform constant 1
C11	Gaussian polynominal coefficient
C2	AFC filter Z transform constant 2
C22	Gaussian polynominal coefficient
C3	AFC filter Z transform constant 3
C4	Normalized AFC VCO gain
C5	AGC Z transform constant 1
C5AMP	RC Amplitude scintillation factor
C5DP	Doppler Z transform constant 1
C5MH	Baseline Z transform constant 1
C5PHA	RC Phase scintillation factor
C6	AGC Z transform constant 2
C6AMP	RF Amplitude scintillation factor

C6DP	Doppler Z transform constant 2
C6MH	Baseline Z transform constant 2
C6PHA	RC Phase scintillation factor
DELF	Delta frequency
DPM	Premodulation filter Z transform constant
DES	DT*SVR
DT	Delta time
DTH1	Delta TH1
DYNR	Dynamic range of AGC below "minimum" signal
D11,22,33	Gaussian polynominal coefficients
E	Voltage into AFC filter
EDOP	Doppler voltage
EDOPR	Doppler rate voltage
EDOPRX	Doppler plus Doppler rate voltage
ENO	Energy to noise density
ENODB	ENO in decibels
ENOM	Minimum ENO
ENOMIN	ENOM in decibels
EPULL	AFC pull in range
ERRDMP	Error count
ERRI	Running count of errors in an interval
ERRDMP	Error count
ERRM	Error spacing matrix
ES	Sweep voltage
EV	Voltage from AFC filter
EVMAX	Maximum sweep voltage
EVMIN	Minimum sweep voltage
EVO	Last EV
EV1	Voltage after Doppler addition
EV1C	Voltage into bit synchronizer
EV1O	Last EV1
EV1OC	Last EV1C
EO	Last E
FBAMP	Amplitude scintillation filter corner

FBPHA	Phase scintillation filter corner
FBTAU3	Corner frequency of TAU3
FBTAU5	Corner frequency of TAU5
FBTAU6	Corner frequency of TAU6
FDIFF	AFC pull in
FDIFFB	Bit synchronizer pull in
FIDO	Float (IDO)
FLO	Lo detune
FQDPRT	Frequency Doppler rate
FRQDOP	Frequency Doppler
FVCOB	Frequency VCO bit synchronizer
F1, F2	Dummy print variables
GAM43	Scintillation filter tap spacing target
GAM43A	GAM43 for amplitude
GAM43P	GAM43 for phase
G1	IF amplifier gain
G1LIM	Maximum G1
HDRI	Truncated ASCII Header
I	Dummy index
IAERRI	Index of AERRI
IAMP	Amplitude scintillation counter
IAMPC	Phase scintillation counter
IBIT	Phase of bit synchronizer
ICAMP	RC amplitude filter counter
ICCLRC	Control variable for RC scintillation
ICDC	Octal bit counter
ICLLN	Control variable for log normal scintillation
ICPHA	RC Phase filter counter
IDATA	Current bit
IDATAO	Last IDATA
IDATAW	Last IDATAO
IDLBIT	Number of output bits before error count
IDO	Number of dropouts
IDON	IDO counter

IDTS	Dummy line index
IDUM	Dummy counter
IERRSP	Error space
IFILT	Dummy line index
IFRAME	Counter to NFRAME
IHOLD	In phase bit synchronizer level
IHOLD1	Last IHOLD
ILOC	Counter, bits to lock
ILOCF	Final ILOC
INCREC	Tape record increment
INCTIM	Tape time increment
IPHA	Phase scintillation counter
IPHAC	Amplitude scintillation counter
IRCD	Register contents data generator
IREC	Record number
IRECB	Bit number in record
IRECO	Dummy record number
IRECT	Total number of records
IRUN	Number of tape problems plus 1
ITAPE	Counter of words in the record
ITH1	Integer of TH1
ITH2	Integer of TH2
ITIM1	Tape time initial
ITIM2	Tape time final
IWORDI	Bit packed word of symbol decisions
IX	Bin of soft decision
IXD	Data bit in the ship register
IXM	Last IX
I1, I11	Random generator number
I2, I22	Random generator number
I5,I55	Random generator number
I6,I66	Random generator number
J	Counter for samples per bit
JJ	Dummy counter

J1, J11	Random generator number
J2, J22	Random generator number
J5, J55	Random generator number
J6, J66	Random generator number
K	AFC VCO gain
KB	Bit synchronizer VCO gain
KKK	Total bits of the measurement
KDATA	Counter of IDATA
KOUNT	Counter of IMS
K1, K11	Random generator number
K2, K22	Random generator number
K5, K55	Random generator number
K6, K66	Random generator number
NACQ	Counter of NACQT trials
NACQT	Number of acquisition
NBIT	Phase of IBIT to dump in phase integrator
NBIT2	Phase of IBIT to dump quadraphase integrator
NC	Quadrature noise
NFRAME	Bit length to define error history
NN	N43-1
NNOUT	NOUT/10
NOUT	Rounded value of IAERRI
NRUNS	Number of bits per run
NS	Quadrature noise
NSPB	Number of samples per bit
NO	Noise density
N43	Number of scintillation filter taps
OMC	Baseband equivalent of IF in radians
OMT	Incremental OMC
OOTH1	Filtered TH1 plus YP
OTH1	Filtered TH1
OTH11	Filtered TH1 back one time
OTH12	Filtered TH1 back two times
PACQ	Probability of acquisition

PFAL	Probability of false acquisition
PEI	Probability of error
PHIB	Steady state bit synchronizer phase error
PHIDEG	Steady state AFC phase error
PHISS	PHIB in radians
PHISSB	PHIDEG in radians
PI	Pi
PI2	2*Pi
PMFILT	Premodulation filter corner
PRNO	Noise list
PROB	Probability list
PROBI	Incremental probability
PROBT	Dummy for probability list
PMISS	Probability of missed acquisition
QERR	Voltage to bit synchronizer filter
QERRO	Last QERR
QV	Voltage from bit synchronizer filter
RCA	Register contents amplitude
RCP	Register contents phase
REMTX	Trignometric routine number
RI	Random number
SBINS1	Probability matrix for -1-1 input
SBINS2	Probability matrix for +1-1 input
SBINS3	Probability matrix for -1+1 input
SBINS4	Probability matrix for +1+1 input
SB1	Hard decisions SBINS1
SB2	Hard decisions SBINS2
SB3	Hard decisions SBINS3
SB4	Hard decisions SBINS4
SDAMP	Gain of amplitude scintillation
SDPHA	Gain of phase scintillation
SGNRT	Sign Doppler ra
SHFTH	TH1 mod PI2
SIG	Normalized noise

SKOU	Standard deviation of acquisition at KDATA
STDAQ	Standard deviation of acquisitions
STDES	Standard deviation of ES
STDEV	Standard deviation of EV
SPEI	Standard deviation of PEI
STH1	Sin (TH1)
STH2	Sin (TH2)
SUYA1,2	RC amplitude filter statistics
SUYP1,2	RC Phase filter statistics
S2A,P	Amplitude, phase gain squared
S22A,P	Amplitude, phase gain sum
SVR	Sweep slope
SVRHZ	SVR in hertz
SWMN	Sweep minimum
SWMX	Sweep maximum
S2A	Amplitude tap gain squared
S2P	Phase tap gain squared
S22A	Amplitude tap gain sum
S22P	Phase tap gain sum
TAUB1	Bit synchronizer filter constant 1
TAUB2	Bit synchronizer filter constant 2
TAUPM	Premodulation filter constant
TAU	AFC filter constant 1
TAU2	AFC filter constant 2
TAU3	AGC filter constant
TAU4	Sample filter constant
TAU5	Baseline filter constant
TAU6	Doppler filter constant
TGA	Tap gain amplitude
TGP	Tap gain phase
TH1	Signal phase
TH11	Th1 back one time
TH12	TH12 back two times
TH2	Phase angle from AFC VCO
TL	Threshold

TSYNC	Period of bit synchronizer VCO
TSYNC2	Half TSYNC
U	Voltage into AGC filter
UMH	Voltage into baseline filter
V	Voltage from AGC filter
VA	Normalized corner frequency of amplitude scintillation filter
VD	Absolute version of V
VDP	Voltage from doppler filter
VMH	Voltage from baseline filter
VP	Normalized corner frequency of phase scintillation filter
VXQ	Voltage at XQ
VXQC	VXQ corrected
WN	AFC loop natural frequency
WNB	Bit synchronizer natural frequency
XI	In phase integrator voltage
XIHOLD	Last XI
XIO	Last XI
XIOO	Last XIO
XISIG	Standard deviation of in-phase integrator voltage
XISUM	Mean of in phase integrator voltage magnitude
XQ	Quadraphase integrator voltage
XQCOR	Voltage XQ corrected
XQO	Last XQ
Y	Absolute value of YA
YA	Scintillation amplitude
YAPO	One plus YA
YAPOA	YAPO in volts
YAX	Normalized RC amplitude
YAXX	Unnormalized RC amplitude
YP	Scintillation phase
YPX	Normalized RC amplitude
YPXX	Normalized RC amplitude
ZETA	AFC damping factor
ZETAB	Bit synchronizer damping factor

APPENDIX V

ERROR RATE

APPENDIX VII
MISCELLANEOUS SUBROUTINES

This appendix presents three subroutines which were found useful in trouble-shooting the receiver during the software development, but were not used in the production runs.

The first is OSCILL which is an oscilloscope and plots three inputs. These are entered into the routine by lists. The routine automatically scales the output.

The second is SURV which is a voltmeter. It gives the mean and standard deviation of the input, as well as the mean and standard deviation of the absolute value of the input.

The third is CHMEM. This was used early in the analysis when there was one conditional probability matrix which was the position by position summation of all four of the matrices of this report, i.e., just P(B/A). It generates information to determine the skew of the matrix.

A subroutine, used to cut the magnetic tapes, which is not included herein is BUFFLT. This is a bit manipulation routine to transfer the 60 bit words of the CDC 6600 to the ARC magnetic tape format. The subroutine is peculiar to the Kronos 2.0 operating system, and is very system oriented, e.g., it is not compatible with the Kronous 2.1. The call statement has 5 arguments: a) identifier of particular tape number, b) read/write/rewind/end-of-file command, c) first and d) last word to be written and e) a number from the subroutine indicating the record number.

APPENDIX X
ALTERNATE CONTINUOUS PHASE MODULATORS

Three alternate continuous phase modulators, a three step upconverter, an indirect FM modulator and a single step upconverter were considered during the course of this study. The latter was finally selected because of its simplicity and minimum parts count. This appendix discusses these alternate designs.

Three Step Upconverter

Figure 1 shows the block diagram for the modulator and upconverter. The 400 MHz FSK signal is synthesized by generating a 1 MHz signal in a voltage controlled crystal oscillator and up-converting this signal by mixing it with higher frequencies derived from a 23 MHz crystal oscillator. The mixing is done in three steps to make filtering practical at each frequency. FSK is accomplished by pulling the 1 MHz VCXO with a $\pm$3.2 volt DC signal amplified from the TTL data.

The oscillators are specified to have an end-of-life long term drift of $\pm$10 ppm. The 1 MHz oscillator is voltage controlled to provide the 64 Hz frequency shift. A VCO was chosen over frequency switching to provide phase continuity between frequencies.

A typical modulation range for a crystal oscillator is 80 ppm (Frequency Electronics, Inc.). For the needed 64 Hz modulation, this requires a 1 MHz center frequency and a DC control voltage of $\pm$3.2 volts. The frequency will typically switch in 20 microseconds.

The power losses and gains are indicated in Figure X-1. The criteria for the design are:

- o An input of 6 dBm into the local oscillator port of the mixer.
- o 0 dBm or less into the signal port to maintain at least a 6 dB ratio to minimize spurs.
- o Limit amplifier gain to approximately 10 dB due to environmental constraints.

The mixers have a loss of approximately 6 dB at a ratio of 6 dB between signal and L.O. (per Relcom Co.).

Filters are provided in the L.O. lines to eliminate the harmonics of the square waves generated by multiplying and dividing. This application is not critical.

Filters are also provided after each mixing operation to eliminate harmonic spurs. The filter bandwidths were chosen to have a -60 dB bandwidth at less than the separation of the closest low order spurs.

The spurs of the first mixer were the closest and a crystal filter is required. The crystal filter is specified by Crystal Network Products. The 2nd and 3rd mixer filters are designed according to Texscan tubular filter specifications and are summarized in Figure 1. The main objection to the Figure 1 design* is its overall hardware complexity, high parts count, and consequently, its lower reliability, higher power consumption, and added weight. Based on information obtained from a crystal oscillator manufacturer alternate designs are possible.

The following are the constraints which dictated the design parameters:

1. The modulation index is .7 radians $\pm$5% over the temperature range of -40°F to +160°F.
2. Over the temperature range, an ovenized oscillator can be pulled a minimum of $\pm$1 ppm and a maximum of $\pm$100 ppm. The minimum value is indicated by a crystal oscillator vendor as being the value one could pull an oscillator to an accuracy of <5%. The maximum is constrained by the phase noise of an oscillator which should be >76 dBc at 100 Hz from the carrier in a 1 Hz bandwidth. To deviate $\pm$31 Hz, this implies a VCXO may be centered between 300 KHz and 30 MHz. However, due to the limitations of practical crystal cuts, the best oscillators are constructed in the 5 to 20 MHz range.
3. The minimum two-sided bandpass filter 3 dB bandwidth is to be 3%. The filter attenuation of the closest spur should be at least 40 dB down at the modulator output. This is because the non-linear power amplifiers will enhance the spurs approximately 15 dB and also create intermodulation products. Because of the extreme temperature range and associated filter drift problems, 60 dB will be used as the design

*M. D. Saferstain, "SAEP Modulator", TRW IOC 7322.4-15, November 19, 1973.

constraint. The filter will have a maximum of 5 poles to minimize filter size and number of elements and maximize reliability.

Given these constraints, two alternate modulator configurations are realizable as shown in Figures X-2 and X-3.

Indirect FM Modulator

The indirect FM modulator design based on the narrowband phase modulator concept conceived by Armstrong, integrates the data, linearly phase modulates the resultant waveform with a modulation index of 0.0775, and multiplies the modulated carrier 8 times to achieve an output frequency of 400 MHz at a modulation index of 0.7. Linear phase modulation is achieved by summing the carrier in quadrature with the double sideband suppressed carrier modulated signal; i.e., the output Y(t) as a function of the input signal X(t) is,

$$Y(t) = \cos(\omega_c t) + X(t)\sin(\omega_c t)$$

$$= \cos(\omega_c t + \tan^{-1}X(t)) \simeq \cos(\omega_c t + X(t))$$

for $|X(t)| << 1$. In this case, $X(t) = \beta\int\phi(t)dt$ where β is the modulation index

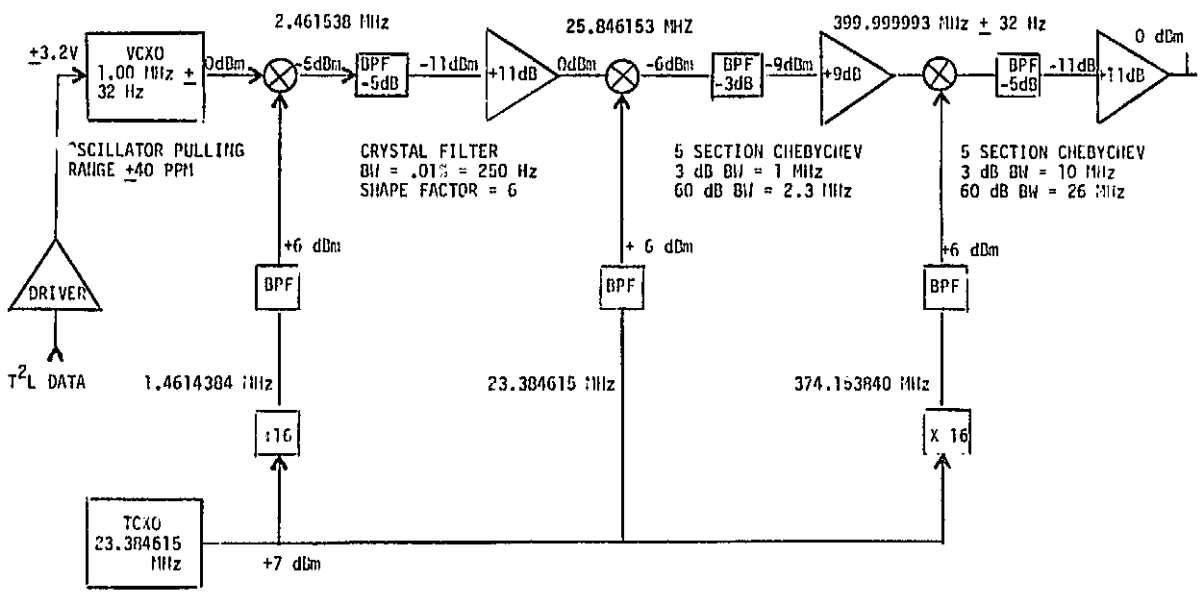

FIGURE X-1
THREE STEP UPCONVERTER MODULATOR

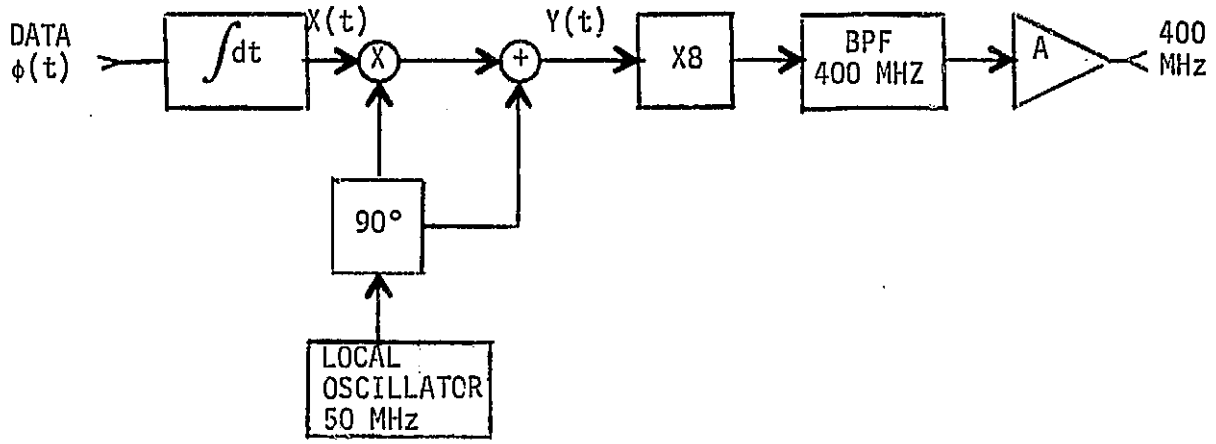

FIGURE X-2
INDIRECT FM MODULATOR

and $\phi(t)$ is the digital data. The one fundamental drawback to this concept is the practical implementation of the integrator and mixer. For long strings of marks or spaces, or where the average number of marks and spaces are not equal, the integrator and mixer must have sufficient dynamic range to operate over the entire period of data transmission. Furthermore, the phase modulation approximation holds only for the range where $|X(t)| << 1$. Since $\tan^{-1}\alpha = \alpha - \frac{\alpha^3}{3} + \frac{\alpha^5}{5} \ldots$, if we modulate one bit at a modulation index of .0775, a string of data where the marks outnumber the spaces by 10 bits would increase the distortion from .2% to 20%**, clearly an unacceptable situation. Lower modulation indices may be possible by decreasing the 50 MHz LO and increasing the multiplication factor. However, in view of the simplicity of the single conversion direct FM design discussed below, this design is untenable.

** The desired signal at the output of an FM modulator is:

$$Y(t) = \cos(\omega_{ct} + \beta\int\phi(t)dt).$$

The actual signal out of the narrowband FM modulator is:

$$Y(t) = \cos\left[\omega_c t + \tan^{-1}(\beta\int\phi(t)dt)\right]$$

$$= \cos\left[\omega_c t + \beta\int\phi(t)dt - \frac{\beta^3}{3}(\int\phi(t)dt)^3 + \frac{\beta^5}{5}(\ )^5 - + \cdots\right]$$

where the higher power terms in the expansion are the distortion terms. If for one bit, $\beta\int\phi(t)dt = .0775$ radians, then the distortion is in the order of $(.0775)^2/3 \approx .2\%$. Where the data is such that $\int\phi(t)dt = 10\int\phi(t)dt$, the distortion increases to $(.775)^2/3 \approx 20\%$.

Single Conversion FM Modulator

The single conversion direct FM modulator shown in Figure 3 takes the 0 dBm output of a FCXO at 20 MHz and upconverts in one step to the output frequency of 400 MHz. The nearest mixer sideband in the upconversion is 40 MHz away using a doubly balanced mixer which also suppresses the 380 MHz LO a minimum of 25 dB. This implies a 3% bandwidth, 5 pole Chebyshev filter may be used at 400 MHz which would result in the 380 MHz LO being attenuated an additional 40 dB to a total level of 65 dB and the 40 MHz sideband attenuated to 68 dB. The total loss in the filter is approximately 5 dB, thus an 11 dB gain amplifier is needed to bring the output to 0 dBm. This modulation technique is simple and straightforward, requiring a minimum of parts, meets all the design constraints and, based on the new oscillator data, is the TRW recommended design.

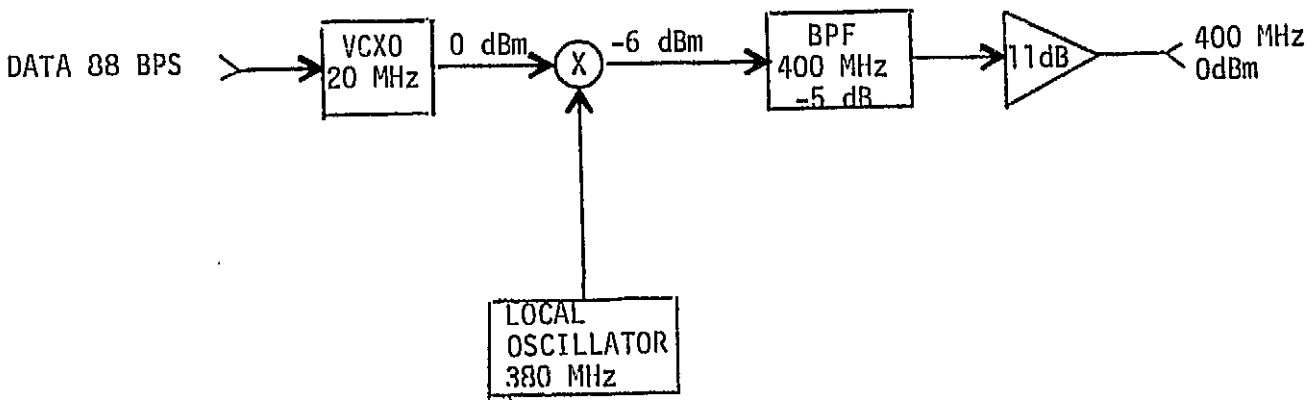

FIGURE X-3
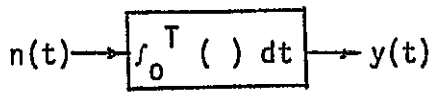
SINGLE CONVERSION DIRECT FM MODULATOR

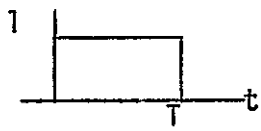
APPENDIX XI

NOISE NORMALIZATION

First, we determine the relationship between the variance of the noise at the input of the system to the variance of the noise at the output of an integrator. The output represents the noise of a transmitted symbol. For the continuous case we have,



with the function h(t)



By convolution

$$y(t) = \int_{-\infty}^{\infty} h(T)\ n\ (T-\tau)\ d\tau \quad ,$$

and squaring we have

$$|y(t)|^2 = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} h(\alpha)\ h^*\ (\beta)\ n\ (T-\alpha)\ n^*\ (T-\beta)\ d\alpha d\beta$$

introducing α and β to keep track of the integrations, and conjugates for real values, the expected square is:

$$E\ \{|y(t)|^2\} = \int_0^T \int_0^T E\ \{n\ (T-\alpha)\ n^*\ (T-\beta)\}\ d\alpha d\beta$$

where outside the interval o to T the integrals are zero, and within the intervals h (α) and h (β) are unity. Now

$$E\ \{n\ (T-\alpha)\ n^*\ (T-\beta)\} = \frac{N_o}{2}\ \delta_{\alpha\beta}\ (\alpha-\beta)$$

where N_o is the single ended noise density KT, and $\delta_{\alpha\beta}$ is the delta function. Thus,

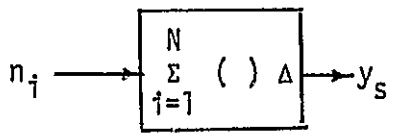
$$E\ \{|y(t)|^2\} = \frac{N_o}{2} \int_o^T \int_o^T \delta_{\alpha\beta}\ (\alpha-\beta)\ d\alpha d\beta$$

of course $\delta_{ij} = 1$ for $i = j$

$\delta_{ij} = 0$ elsewhere,

so $E\ \{|y(t)|\}^2 = \frac{N_o T}{2}$.

For the sampled case



where $\Delta N = T$

We have as before

$$E\ \{y_s y_s^*\} = \sum_{i=1}^{N} \sum_{j=1}^{N} \Delta^2\ \{E\ n_i n_j^*\} \ .$$

Defining $E\ \{n_i n_j^*\} = \sigma^2\ \delta_{ij}$

then $E\ \{y_s y^*\} = N\ \sigma^2 \Delta^2$.

Equating the continuous and sampled cases

$$\frac{N_o T}{2} = N\ \sigma^2 \Delta^2$$

or $$\sigma^2 = \frac{N_o T}{2}$$

$$= \frac{N}{\quad} \cdot \frac{1}{N}\frac{1}{\Delta}\frac{N}{T}$$

$$\frac{N_o}{2\Delta} \quad ,$$

is the total variance, each quaturature component being $\frac{N_o}{4\Delta}$.

In the initial report, the noise was

$$n(t) = n_s \sin w_o t + u_c \cos w_o t$$

where w_o is the carrier, so that in complex amplitudes

$$\tilde{n}(t) = n_c - jn_s$$

together with the signal

$$s(t) = \sqrt{2}\, A \sin (w_o t + \theta_1)$$

or

$$\tilde{s}(t) = -j\sqrt{2}\, A\, e^{+j\theta_1}$$

giving

$$\tilde{s}(t)+\tilde{n}(t) = -j\sqrt{2}\, A \cos\theta_1 - j\sqrt{2}\, Aj \sin\theta_1 + n_c - jns$$

$$= \sqrt{2}\, A \sin\theta_1 + n_c - j\sqrt{2}\, A \cos\theta_1 - jns \, .$$

However, looking at the noise

$$n^2(t) = n_s^2 \sin^2 w_o t + 2 n_c n_s \sin w_o t \cos w_o t + n_c^2 \cos^2 w_o t$$

then

$$E\{n^2(t)\} = E\{n_s^2\}\frac{1}{2} + 0 + E\{n_c^2\}\frac{1}{2} \quad ,$$

as obviously from trignometry

$$E\{\sin w_o t \cos w_o t\} = 0$$

and as the samples by definition are independent

$$E\{n_c n_s\} = 0 \quad .$$

From our previous report

$$n_s = n_c = N_o/(4\Delta)$$

then

$$\frac{N_o}{2\Delta} \neq \frac{N_o}{4\Delta}\frac{1}{2} + \frac{N_o}{4\Delta}\frac{1}{2} \quad .$$

Herein, the noise is

$$n(t) = \sqrt{2}\, n_s \sin w_o t + \sqrt{2}\, n_c \cos w_o t,$$

so that squaring

$$n^2(t) = 2n_s{}^2 \sin^2 s_o t + 4n_c n_s \sin w_o t \cos w_o t + 2n_c{}^2 \cos^2 w_o t$$

then taking the expectation

$$E\{n^2(t)\} = 2E\{n_s{}^2\}\frac{1}{2} + 0 + 2E\{n_c{}^2\}\frac{1}{2}$$

$$= E\{n_s{}^2\} + E\{n_c{}^2\} \quad .$$

Therefore $\tilde{n}(t) = \sqrt{2}\,(n_c - jn_s)$

i.e., $\sqrt{2}\,\mathrm{Re}\,[(n_c - jn_s)e^{jw_o t}] = \sqrt{2}\,\mathrm{Re}\,[n_c \cos w_o t + jn_c \sin w_o t - jn_s \cos w_o t - jnsjsin w_o t]$

$$= \sqrt{2}\,[n_c \cos w_o t + n_s \sin w_o t] \quad .$$

Thus, $\tilde{s}(t)+\tilde{n}(t) = -j\sqrt{2}A\cos\theta_1 - j\sqrt{2}Aj\sin\theta_1 + \sqrt{2}n_c - \sqrt{2}jn_s$

$$= \sqrt{2}A\sin\theta_1 + \sqrt{2}n_c - j\sqrt{2}A\cos\theta_1 - \sqrt{2}jn_s ,$$

as herein expressed.

Summarizing, in the previous report we had

$\tilde{x}(t) = \sqrt{2}A\sin\theta_1 + n_s - j[\sqrt{2}A\cos\theta_1 + n_c]$ → (×) → $\tilde{z}(t) = \{\sqrt{2}A\sin\theta_1 + n_2 - j[\sqrt{2}A\cos\theta_1 + n_c]\} e^{-j\theta}$

$\tilde{y}(t) = e^{j\theta}$

by interchanging the random variables n_c and n_s.

Now, we have

$\tilde{x}(t) = A\sin\theta_1 + n_s - j[A\cos\theta_1 + n_c]$ → (×) → $\tilde{z}(t) = \{A\sin\theta_1 + n_s - j[A\cos\theta_1 + n_c]\}\sqrt{2}e^{-j\theta}$

$\tilde{y}(t) = \sqrt{2}e^{-j\theta}$

Note that the multiplier, the local oscillator, $\tilde{y}(t)$, magnitude is irrelevant; the ratio of signal to noise is relevant. In the previous report the noise voltage was $\sqrt{2}$ (3dB) low.

APPENDIX XII

PHASE ERROR

In a low data rate system, high Doppler environment, a phase locked loop tracking the modulating waveform is an attractive receiver implementation. The focal point of this implementation is the phase error.

The first step is to analyze the system without premodulation filtering. Figure XII-1 illustrates the system, where in this paragraph the premodulation filter P(S) = 1. The tracking filter is the usual

$$F(S) = \frac{\tau_2 S+1}{\tau_1 S+1},$$

where $\tau_2 = (2/\omega_n)(\zeta - \frac{1}{2\omega_n\tau_1})$

and τ_1 is arbitrary. In transform notation then the error signal for the unfiltered case is

$$E(S) = (\frac{\omega_\Delta}{S^2}) \{\frac{S[S+(1/\tau_1)]}{S^2+2\zeta\omega_n S+\omega_n{}^2}\}$$

where of course ω_Δ is the step size of a step change in frequency,

$$2\zeta\omega_n = (1+\tau_2 K)/\tau_1$$

and $$\omega_n{}^2 = K/\tau_1$$

Using the transform

$$\mathcal{L}^{-1} \frac{a_1 S+a_0}{S[(S+\alpha)^2+\beta^2]} = \frac{a_0}{\beta_0{}^2} + \frac{[(a_0-a_1\alpha)^2+(a_1\beta)^2]^{1/2} e^{-\alpha t}\sin(\beta t+\psi)}{\beta\beta_0}$$

where $\beta_0{}^2 = \alpha^2+\beta^2$

and $$\psi = \psi_1 - \psi_2 = \tan^{-1}\frac{a_1\beta}{a_0-a_1\alpha} - \tan^{-1}\frac{\beta}{-\alpha},$$

the error signal is

$$E(t) = \omega_\Delta \left\{\frac{(1/\tau_1)}{\omega_n{}^2} + \frac{[((1/\tau_1)-(1)\zeta\omega_n)^2+((1)\omega_n\sqrt{1-\zeta^2})^2]^{1/2}}{\omega_n\sqrt{1-\zeta^2}\omega_n} e^{-\zeta\omega_n t}\right.$$

$$\left. \cdot \sin(\omega_n\sqrt{1-\zeta^2}t+\psi)\right\}$$

The substitutions are of course

$$a_1=1$$

$$a_o=(1/\tau_1)$$

$$\alpha^2+\beta^2=\omega_n{}^2$$

$$\alpha=\zeta\omega_n$$

and $$\beta^2=\omega_n{}^2(1-\zeta^2)\,.$$

Letting A be the first term, and B the factor before the exponential, the maximum frequency error is

$$\frac{d}{dt}\{A+B\exp(-\zeta\omega_n t)\sin(\omega_n\sqrt{1-\zeta^2}t+\psi)\}\omega_\Delta=0\,,$$

or $$\tan(\omega_n\sqrt{1-\zeta^2}t+\psi)=\frac{(1-\zeta^2)^{1/2}}{\zeta}$$

Now, whenever

$$1/\tau_1 << \zeta\omega_n\,,\ (\zeta K >> \omega_n)$$

as is the usual design case

$$\psi_1 = \tan^{-1}\frac{\omega_n\sqrt{1-\zeta^2}}{(1/\tau_1)-\zeta\omega_n} \simeq \tan^{-1}\frac{\sqrt{1-\zeta^2}}{-\zeta}$$

and $$\psi_2 = \tan^{-1}\frac{\omega_n\sqrt{1-\zeta^2}}{-\zeta\omega_n} = \tan^{-1}\frac{\sqrt{1-\zeta^2}}{-\zeta}$$

or $$\tan(\omega_n\sqrt{1-\zeta^2}t)=(1-\zeta^2)^{1/2}/\zeta,$$

thus $$\frac{d}{dt}\{E[\tan^{-1}(\frac{\sqrt{1-\zeta^2}}{\zeta})/(\omega_n\sqrt{1-\zeta^2})]\} = 0$$

yields the time of the maximum error. Substituting this time into the general error expression, the maximum phase error is

$$E_{max} = \frac{\omega_\Delta}{\omega_n}\{\frac{1}{\tau_1\omega_n} + \exp\,[-\frac{\zeta}{\sqrt{1-\zeta^2}}\tan^{-1}\frac{\sqrt{1-\zeta^2}}{\zeta}]\}.$$

The maximum phase error is shown in Figure XII-2, together with a break lock approximation

$$\omega_\Delta/\omega_n = 1.8\ (\zeta+1).$$

It is seen that the design point is near break lock, $\pi/2$ radians, without noise.

Following the same line of thought as in the phase error case, the output is

$$O(S) = \frac{\omega_\Delta}{S^2} \frac{S((\tau_2/\tau_1)S+(1/\tau_1))}{S^2+2\zeta\omega_n S+\omega_n{}^2}$$

and with the same conditions as before,

$$O(t) = \frac{\omega_\Delta}{\omega_n} \{\frac{1}{\tau_1\omega_n} + \frac{\tau_2/\tau_1}{\sqrt{1-\zeta^2}} \exp\ (-\zeta\omega_n t)\ \sin(\omega_n\sqrt{1-\zeta^2}t)\}.$$

In the same form

$$E(t) = \frac{\omega_\Delta}{\omega_n} \{\frac{1}{\tau_1\omega_n} + \frac{1}{\sqrt{1-\zeta^2}} \exp\ (-\zeta\omega_n t)\ \sin(\omega_n\sqrt{1-\zeta^2}t)\}.$$

The premodulation filter is taken as

$$P(S) = 1/(\tau_p S+1)^2$$

The error signal is now

$$E(S) = (\frac{\omega_\Delta}{S^2})\ (\frac{1}{\tau_p S+1})^2 \left[\frac{S[S+(1/\tau_1)]}{S^2+2\zeta\omega_n S+\omega_n{}^2}\right]$$

The term as noted before

$$\mathcal{L}^{-1} \frac{S+(1/\tau_1)}{S[S^2+2\zeta\omega_n S+\omega_n{}^2]} = \frac{1}{\tau_1\omega_n{}^2} + \frac{1}{\omega_n\sqrt{1-\zeta^2}}\ e^{\zeta\omega_n t}\ \sin(\omega_n\sqrt{1-\zeta^2}t)$$

together with

$$\mathcal{L}^{-1}\frac{1}{(\tau_p S+1)^2} = \frac{t}{\tau_p^2}\,e^{-t/\tau_p}$$

can be convolved

$$\int_0^t F_1(t-\tau)F_2(\tau)\,d\tau$$

for the result, i.e.,

$$E(t) = \omega_\Delta \int_0^t \frac{t-\tau}{\tau_p^2}\,e^{-\frac{t-\tau}{\tau_p}}\left(\frac{1}{\tau_1\omega_n^2} + \frac{1}{\omega_n\sqrt{1-\zeta^2}}\,e^{-\zeta\omega_n t}\sin(\omega_n\sqrt{1-\zeta^2}\,t)\right)d\tau,$$

or

$$E(t)/\omega_\Delta = \frac{e^{-t/\tau_p}}{\tau_p^2}\int_0^t \{tAe^{\tau/\tau_p} - \tau Ae^{\tau/\tau_p} + \frac{t}{b}\,e^{\tau/\tau_p}\,e^{-a\tau}\sin b\tau$$

$$- \frac{\tau}{b}\,e^{\tau/\tau_p}\,e^{-a\tau}\sin b\tau\}d\tau,$$

where $A = 1/(\tau_1\omega_n^2)$

$b = \omega_n\sqrt{1-\zeta^2}$

and $a = \zeta\omega_n$.

The first two integrals are straight forwardly evaluated:

$$tA\int_0^t e^{\tau/\tau_p}\,d\tau = \frac{tAe^{\tau/\tau_p}}{(1/\tau_p)}\Big|_0^t = tA\tau_p(e^{t/\tau_p}-1)$$

and

$$-A\int_0^t \tau e^{\tau/\tau_p}\,d\tau = \frac{-Ae^{\tau/\tau_p}}{(1/\tau_p)^2}\left(\frac{\tau}{\tau_p} - 1\right)\Big|_0^t$$

$$= -A\tau_p\left(e^{t/\tau_p}\left(\frac{t}{\tau_p} - 1\right)+1\right).$$

The third, somewhat more complex

$$\frac{t}{b}\int_0^t e^{(1/\tau_p - a)\tau} \sin b\tau \, d\tau = \frac{t}{b} e^{a'\tau} \frac{(a' \sin b\tau - b \cos b\tau)}{a'^2+b^2}\Big|_0^t$$

$$= \frac{t}{b(a'^2+b^2)} \{e^{a't}(a' \sin bt - b \cos bt)+b\}$$

where $a' = (1/\tau_p) - a$

Finally, the last is

$$-\frac{1}{b}\int_0^t \tau e^{a'\tau} \sin b\tau \, d\tau = \frac{-\tau e^{a'\tau}}{b(a'^2+b^2)} \{a' \sin b\tau - b \cos b\tau\}_0^t$$

$$+ \frac{e^{a'\tau}}{b(a'^2+b^2)^2} \{(a'^2-b^2) \sin b\tau - 2a'b \cos b\tau\}_0^t$$

$$= \frac{-te^{a't}}{b(a'^2+b^2)} \{a' \sin bt - b \cos bt\} + \frac{e^{a't}}{b(a'^2+b^2)^2}$$

$$\cdot\{(a'^2-b^2)\sin bt - 2a'b \cos bt\} - \frac{1}{b(a'^2+b^2)^2} \{-2a'b\}.$$

Combining

$$E(t)/\omega_\Delta = A+\bar{e}^{t/\tau_p} \{-\frac{tA}{\tau_p} - A + \frac{t}{\tau_p^2(a'^2+b^2)} + \frac{2a'}{\tau_p^2(a'^2+b^2)^2}\} +$$

$$+ \frac{\bar{e}^{at}}{\tau_p^2 b(a'^2+b^2)^2} \{(a'^2+b^2) \sin bt - 2a'b \cos bt\}.$$

Following the same steps for the output,

$$O(t)/\omega_\Delta = A+ \bar{e}^{t/\tau_p}\{- \frac{tA}{\tau_p} - A + \frac{b't}{\tau_p^2(a'^2+b^2)} + \frac{2a'b}{\tau_p^2(a'^2+b^2)^2} \}+$$

$$+ \frac{b' \bar{e}^{at}}{\tau_p^2 b(a'^2+b^2)^2} \{(a'^2+b^2)\sin bt - 2a'b \cos bt\},$$

where $b' = \tau_2/\tau_1$.

The expressions for phase error and output voltage are fairly straight forward

$$A+(B+Ct)\exp(-Dt)+(E\sin(bt)-B\cos(bt))\exp(-at)$$

where the coefficients vary with and without filtering; for the error or output signals. Table XII-1 lists the coefficients utilizing the intermediate symbols

$a = \zeta\omega_n$

$a' = 1/(\tau_p) - a$

$b = \omega_n\sqrt{1-\zeta^2}$

$b' = \tau_2/\tau_1$

$\Sigma = a'^2 + b^2$

$\Delta = a'^2 - b^2$

TABLE XII-1

Figure XII-3 compares filtered and unfiltered responses. Obviously the pre-modulation filter reduces the potential of break lock. Similarly a wider bandwidth also reduces the maximum phase error. Figures XII-4 and XII-5 show

several of the voltage histories for a "worst case" 62 Hertz step, and a "best case" alternating ±31 Hertz steps. (A PN sequence is bounded by these cases.) For the worst case sequence, a narrow loop potentially always breaks lock, even without noise, near the end of the symbol. Increasing loop bandwidth drastically reduces this possibility. The output signal level decreases with increasing bandwidth moderately for worst case sequences, but only slightly for best case sequences. The integral of the output, a measure of energy to the detector, is tabulated on the figure.

The foregoing theoretical expressions can be readily compared with the simulation. This is shown in Figures XII-6 and XII-7. These are "intensity" plots of 1900 overlaid one symbol traces at the multiplier output. In these intensity plots the number of "hits" on a position are quantized into five levels, "=", "+", ":", ".", and " ". It can be seen that the simulation intensity follows the theoretical curves, but a large variance about the mean is evident. A fast Fourier transform of the traces, Figure XII-8, shows that (at the phase detector output) considerable high frequency "noise" is present, i.e., noise not in the loop bandwidth as normally defined in linear loops. As this is before the loop filter the noise is "white", or as white as the sampling permits. By prefiltering this noise, i.e., a low pass filter before the "oscilloscope" (the subroutine which makes the picture); with a corner relative to the loop bandwidth, PEFILT, the phase variance at high signal to noise approaches the linear (high SNR) theory

$$\sigma_\phi^2 = 1/(SNR) = (N_o/E)TB_L$$

as shown in Figure XII-9. With PEFILT then the simulated phase variance in Figures XII-10 and XII-11 are quite similar to the foregoing theory (the "real" filter time delays not present in the linearized analysis are evident in the figure).

APPENDIX XIV
THEORETICAL CHARACTERIZATION

This appendix attempts to theoretically characterize the simulation data. If the simulation data is compared with "ideal" receivers as in Figure XIV-1, two things are apparent; first, these theories do not describe the simulation very well, and second, the effects of scintillation are not considered. By "ideal" the following mean error expressions are inferred: ideal coherent, $.5 \text{ erfc } (E/N_o)^{1/2}$, nonideal coherent, $.5 \text{ erfc } (E/(2N_o))^{1/2}$ and ideal noncoherent, $.5 \exp(-E/(2N_o))^{1/2}$. One theory that does both is presented by Turin (Ref. 6). In exploring this theory, both coherent and noncoherent systems will be considered.

The key parameter in this theory is the complex cross correlation coefficient of the signal waveforms

$$\lambda = \frac{1}{2E}\int_0^T \zeta_1^*(t)\ \zeta_2(t)\ dt,$$

where the signal waveforms, in complex amplitude notation are

$$\zeta_i(t) = x_i(t)\ \exp(j\omega_o t)$$

where $i = 1,2$

herein, and ω_o is the carrier, and $x_i(t)$ is

$$x_i(t) = A(t)\ \exp(j\phi)$$

ϕ being the phase. By way of explanation, for "conventional" coherent phase shift keying (PSK)

$$x_i(t) = \exp(\pm j\theta);\ \theta = \pi/2$$

and for "conventional" noncoherent frequency shift keying (FSK)

$$x_i(t) = A(t)\ \exp(\pm j\pi\Delta f t)$$

with Δf the tone separation. The signal energy in the initial expression is of course

$$E = \frac{1}{2}\int_0^T |\zeta_i(t)|^2 dt,$$

The signals are assumed to be of equal energy, and the channel herein is assumed to be Rician, i.e., the received signal is

$$n_i(t) = x_i(t-\tau)[\alpha \exp(-j\delta) + s \exp(-j\varepsilon)] \exp(j2\pi f_0 t)$$

with τ the delay, α and δ the fixed path strength and phase, and s and ε the random path strength and phase. The random path strength is Rayleigh with a mean square of $2\sigma^2$ and a uniform phase. Thus "burstiness" <u>per se</u> is not definable.

The ideal coherent receiver's decision is via the greater of

$$\frac{\sigma^2}{N_0} |r_i(\tau)|^2 + \alpha \mathrm{Re}\{r_i(\tau) \exp - j\delta\} \qquad i = 1 \text{ or } 2$$

where $r_i(\tau) = \frac{1}{2}\int z^*(t) x_i(t-\tau)\, dt$

given the received version z(t) of x(t). In addition to knowing δ(a "tight" loop) the receiver also knows $\sigma^2/\alpha N_0$.

The noncoherent receiver decides only on $|r_i(\tau)|$.

In either case the error function is

$$P_e = Q(ac,bc) - \frac{1}{2}\left[1 + \frac{\mu\sqrt{1-|\lambda|^2}}{\sqrt{1-\mu^2|\lambda|^2}}\right] \exp\left[-(a^2+b^2)c^2/2\right) I_0(abc^2)$$

where the Marcum Q function is

$$Q(x,y) = \int_y^\infty t \exp(-(t^2+x^2)/2) I_0(xt) dt,$$

$I_0(x)$ is the modified bessel function, and

$$\mu = \beta/(\beta+2)$$
$$\beta = 2\sigma^2 E/No$$
$$\gamma = \alpha/\sigma \ .$$

For the coherent receiver

$$a = \sqrt{1 - \frac{\sqrt{(1-|\lambda|^2)(1-\mu^2|\lambda|^2)}}{1-\mu|\lambda|^2}}$$

$$b = \sqrt{1 + \frac{\sqrt{(1-|\lambda|^2)(1-\mu^2|\lambda|^2)}}{1-\mu|\lambda|^2}}$$

and $$c = \sqrt{\frac{\mu\gamma^2}{2}\ \frac{1-\mu|\lambda|^2}{1-\mu^2|\lambda|^2}}$$

The next step is to apply the algorithm to the candidate Modem. Herein

$$x_i(t) = A(t)\exp j(\mp 2\pi\Delta f/2 \pm 2\pi\Delta f F(t))$$

where $$F(t) = \mathcal{L}^{-1}\ \frac{1}{s}\ \frac{1}{(\tau s+1)^n}$$

Thus $$\lambda = \frac{1}{2(T/2)} \int_0^T \exp j(+2\pi\Delta f t - 4\pi\Delta f t F(t))dt$$

Figure XIV-2 illustrates the results of the integration.

Finally, the candidate modem is characterized by evaluating complex cross correlation coefficient of the signal in question, a tone separation of 62 Hertz and a premodulation filter of .7. The magnitude of the coefficient is .2401 and the real part is .2278. Figure XIV-3 is a plot of the simulation data, and both coherent and noncoherent ideal receivers (for this signal structure), with and without scintillation. For the nonscintillation case the candidate Modem appears to be similar to a differentially coherent phase shift keyed (DPSK) system, i.e., it appears noncoherent at low E/N_0 and coherent at high E/N_0. With scintillation the candidate Modem appears to be noncoherent with a 1 dB degradation from an ideal receiver.
