SUMMARY

A theoretical method is presented for the computation of the flow field about an axisymmetric body operating in a viscous incompressible fluid. This approach combines a smoothing routine, a potential flow method based on a surface source distribution, and a finite-difference boundary-layer method to accomplish the analysis. An empirical method used for modeling separated flow is shown to work reasonably well for cases of extreme flow separation. Results obtained by this method are presented which show very good agreement with experimental data. Suggestions are made for extending this method both to include a better model for separated flow and to calculate the "viscous" flow about axisymmetric bodies at angle of attack. A detailed instruction manual for inputting data to the computer program is given in Appendix A. Appendix B contains the necessary information to place this program on to a computer. This appendix also contains a complete description of output parameters from the computer program, as well as basic flow charts of some of the major subroutines. Appendix C contains a complete listing of the computer program for operation on either a CDC or an IBM computer.

A THEORETICAL METHOD
FOR THE ANALYSIS AND DESIGN
OF AXISYMMETRIC BODIES

by T. D. Beatty
McDonnell Douglas Aircraft Corporation

One of the ultimate goals in aerodynamics is the achievement of the ability to obtain the real fluid flow field about an arbitrary three-dimensional configuration by theoretical calculation rather than by resorting to expensive and time consuming wind tunnel tests. The exact treatment of this problem requires the solution of the full Navier-Stokes equations, which is currently not practical. However, a good approximation to this real flow can be obtained by displacing the surface boundaries of the original body to account for viscosity as shown by Thwaites in Reference (1).

This technique of displacing the boundary surface to obtain a viscous solution has been used in two-dimensional flows quite successfully, as shown in References 2, 3, and 4. The extension of this approach to three-dimensional flow requires that appropriate computational routines be available to calculate the potential and viscous flow parameters. A potential flow routine which can calculate the flow about arbitrary three-dimensional bodies is available (Reference 5), although the comparable three-dimensional boundary layer method is not currently in the state of the art. At the present time, the general three-dimensional problem cannot be solved. However, both an axisymmetric potential flow method and an axisymmetric boundary layer method which can calculate the inviscid and viscous flow field about a body of revolution at zero degrees angle of attack are currently available.

Because of its simple nature and its common appearance in fluid dynamics, it was decided that a body of revolution would be a good starting point for the development of a three-dimensional method for calculating inviscid and viscous flow fields.

The axisymmetric potential flow routine (References 6 & 7), used in the present method was developed at the Douglas Aircraft Company under the guidance of A. M. O. Smith and has proven over the years to be an extremely versatile

and accurate method, as well as the only purely axisymmetric potential flow method, generally available in industry today. This method has been well disseminated throughout industry; only a brief discussion will, therefore, be presented in a following section.

The boundary layer method presented in this report (Reference 8) is a finite difference technique which uses an eddy-viscosity concept to replace the Reynolds shear stress term. Since this method is relatively new and has been modified extensively since Reference 8 was reported, a detailed description will be presented.

The capability of the present method to determine the viscous flow about axisymmetric bodies is shown by correlations between the calculated results and experimental data.

Recommendations are presented for extending the present method to the calculation of the flow field about axisymmetric bodies at angle of attack.

DEFINITION OF SYMBOLS

A	Damping length or frontal area, wherever applicable
A ⁺	Damping constants
C _F	Total skin friction coefficient
C _P	Pressure coefficient
c	Chord
c _f	Local skin friction coefficient $\tau_w / (\frac{1}{2}\rho u_e^2)$
D	Maximum diameter
f	Dimensionless stream function
G	Spot formation parameter
H	Shape factor, θ/δ
K _L	Mixing-length constant
k	Power to determine 2-D or axisymmetric flow
L	Reference body length
l	Mixing length
P ⁺	Pressure gradient parameter
R _C	Chord Reynolds number, $u_\infty c/\nu$
R _D	Diameter Reynolds number, $u_\infty D/\nu$
R _x	Local Reynolds number, $u_e x/\nu$
R _θ	Momentum thickness Reynolds number, $U_e \theta/\nu$
r	Radial distance from axis of revolution
r _o	Local radius of body of revolution
T	Absolute temperature, °K or °R.
t	Transverse curvature term
U _∞	Free stream velocity
u _τ	Friction velocity, $\sqrt{\tau_w/\rho}$
u	x component of velocity

u_e	Velocity at edge of boundary layer
v	y-component of velocity
x	Distance along surface measured from leading edge or from stagnation point
y	Distance normal to the surface of the body
α	Angle between normal to the surface y and the radius r
α	Constant in outer eddy viscosity equation
β	Dimensionless velocity - gradient term, $\beta = (2\xi/u_e)(du_e/d\xi)$
γ_{Tr}	Transitional parameter
δ	Boundary layer thickness
δ^*	Boundary layer displacement thickness
ϵ	Eddy viscosity
ϵ^+	Ratio of eddy viscosity to kinematic viscosity, ϵ/ν
η	Transformed y-coordinate
θ	Momentum Thickness
μ	Dynamic viscosity
ν	Kinematic viscosity
ξ	Transformed x-coordinate
ρ	Density
τ	Shear stress

SUBSCRIPTS

c	Switching point between the inner and outer eddy viscosity formulas
e	Outer edge of boundary layer
i	Inner region
l	Laminar

o Outer Region

t Turbulent

Tr Transition

w Wall

∞ Free-stream conditions

Primes denote differentiation with respect to η .

TECHNICAL DISCUSSION

Geometry Definition

The geometry input to the Douglas Neumann Potential Flow Program must satisfy two primary requirements: the coordinates must be distributed properly and the surface curvature must be smooth. These requirements are easily achieved on an analytical body shape, since the input coordinates may be calculated exactly for any prescribed distribution. However, some method of determining accurate input coordinates for an arbitrary axisymmetric body is necessary, since the body may not always be amenable to exact analytical definition. The approach adopted in the following method is to assume that the coordinates are input in the proper distribution about the body, but that they are not necessarily smooth. These two requirements will be discussed in some detail in the following sections.

Point distribution. - In order to obtain a high degree of accuracy in defining a pressure distribution when using the Douglas Neumann Potential Flow program, surface coordinates should be concentrated in regions of high surface curvature where rapid changes in the surface pressures would be expected. Since the total number of points per body is fixed, the distribution of these points about the body contour becomes extremely important. The Neumann program uses the input coordinates to create linear segments between points, thus approximating the body by a series of Frustums of Cones. The basis distribution required is then quite simple: more points and thus smaller segment sizes in regions of high curvature and less points and thus larger segment sizes in the other areas of the body. The basic guidelines to follow to insure proper point distribution are simply that the surface lengths of adjacent elements should not change by more than twenty to thirty percent and the maximum length of any segment should not exceed either five percent of the body chord or fifty percent of the local body thickness.

Smoothness of input coordinates. - The Douglas Neumann program, or any similar potential flow method, is sensitive to the derivative of the surface slopes, or the curvature of the surface. The surface defined by the input coordinates must therefore have smooth first and second derivatives. The approach used in the

present method to smooth these coordinates, is a five point smoothing routine, which assumes that the input coordinates are smooth and continuous to graphical accuracy, i.e., points are chosen from a small graph (approximately a 10 inch chord). The output points from this routine will be moved very slightly to smooth the derivatives, but this movement will be negligible as far as the body shape is concerned. The equations used to accomplish this smoothing are as follows:

$$\bar{x}_j = \frac{1}{16} \left\{ -x_{j-2} + 4x_{j-1} + 10x_j + 4x_{j+1} - x_{j+2} \right\} \quad (1a)$$

$$\bar{y}_j = \frac{1}{16} \left\{ -y_{j-2} + 4y_{j-1} + 10y_j + 4y_{j+1} - y_{j+2} \right\} \quad (1b)$$

where x_j and y_j are the unsmoothed input coordinates

and \bar{x}_j and \bar{y}_j are the smoothed coordinates.

Potential Flow Method

The Douglas Neumann method, (References 6 and 7) is very general in that it can calculate the potential flow about virtually any body. There is no restriction, for example, to slender bodies; in fact, the "body" in question need not be a single body but may be an ensemble of bodies. In principle, the calculated solution may be made as accurate as desired by suitably refining the numerical procedure; accordingly, the so-called Neumann method is designated an exact method in this sense.

The Neumann method is based on the use of a distribution of source density over the body surface. Applying the condition of zero normal velocity on the body surface yields an integral equation for the source distribution. Specifically, the equation is a Fredholm integral equation of the second kind over the body surface. Once this has been solved for the source distribution, all flow quantities of interest, i.e., velocity, pressure, etc., can be calculated by rapid straightforward procedures. To implement this method on a computer, the body surface is approximated by a large number of small surface segments, over each of which the source density is assumed constant. The

integral equation is replaced by a set of linear algebraic equations for the values of the source density on the segments. Input to the computer program consists of the coordinates of a set of points defining the body surface; these points are then used to determine the surface segments for approximating the body. There is no assumption made that the body can be analytically represented.

The usefulness of potential flow with its neglect of viscosity and compressibility is due to the fact that it is a good approximation to real flow under a wide variety of circumstances. With regard to viscosity, the program obtains useful results except in regions of catastrophic separation. To verify the usefulness of potential flow as a predictor of real flow, results calculated by the Neumann program have been compared with experimental data. Several collections of comparisons have been made. Reference 9 was a very complete collection but is now rather old. Reference 10 is a more recent collection that shows a smaller number of comparisons. In the calculation of the viscous flow about axisymmetric bodies it is necessary to add the boundary layer displacement thickness to the body as will be shown in a subsequent section. This results in an "open" trailing edge body. This "open" body can be evaluated by the Neumann program without any difficulty even though the boundary surface does not close. Reference 11 presents an explanation of this phenomenon which proceeds as follows: for a closed body the integral of the source density over the body is zero; for an "open" trailing edge body, this integral is not zero, and a streamtube leaves the trailing edge of the open body which proceeds downstream and approaches infinity parallel to \vec{u}_∞ as a constant cross section streamtube. Thus, the flow that is calculated may be thought of as that about a semi-infinite body consisting of the open body and an extension defined by this streamtube. The shape of the extension is unknown but is presumably unique, having both zero normal velocity and zero source density.

The potential flow program has many useful options available which do not pertain directly to the present development. The details of these options are described in References 12 through 17.

Boundary Layer Method

Basic boundary layer equations. - The calculation of the viscous flow over an axisymmetric body involves the solution of the laminar and turbulent flow equations. For laminar flows, the problem is strictly mathematical because the governing differential equations can be written exactly. For turbulent flows on the other hand, an exact solution of the governing equations is not possible. Consequently, in order to proceed at all, one must rely on a certain degree of empiricism. In the past, most of the work in this area has concentrated on so-called momentum and/or energy integral methods as a means of evaluating the viscous flow parameters. Thus, the exact mathematical solution to the problems of the turbulent flow was bypassed, leading to fast and simple methods with varying degrees of accuracy. These methods usually rely quite heavily on empirical correlations and generally are restricted to a limited range of flow conditions.

The Douglas Boundary-Layer Method (Reference 8), eliminates many of the disadvantages of the integral methods by proceeding to solve the full partial-differential equations governing the flow, thereby, being classified as a differential method. For two-dimensional and axisymmetric incompressible flows, turbulent boundary-layer equations contain terms involving time means of fluctuating velocity components known as Reynolds stress terms. At present the exact relationship between these terms and the mean velocity distribution in the boundary layer still remains unknown. In the present method, a relation based on the eddy-viscosity concept is used giving highly satisfactory results for a variety of flow conditions.

If the normal-stress terms are neglected, the incompressible turbulent boundary-layer equations for two-dimensional and axisymmetric flows can be written as in Reference 8:

Continuity

$$\frac{\partial}{\partial x} [r^k u] + \frac{\partial}{\partial y} [r^k v] = 0 \quad (2)$$

Momentum

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = u_e \frac{du_e}{dx} + \frac{1}{\rho_\infty} \frac{1}{r^k} \frac{\partial}{\partial y} (r^k \tau) \quad (3)$$

where

$$\tau = \tau_\ell + \tau_t$$

with

$$\tau_\ell = \mu_\infty \frac{\partial u}{\partial y} \quad (\text{For laminar flow only}) \quad (4)$$

$$\tau_t = -\rho_\infty \overline{u'v'} \quad (\text{Additional term due to turbulent flow})$$

and

$$\overline{u'v'} = \text{Reynolds shear stress term}$$

$$k = 0 \quad \text{for two-dimensional flow}$$

$$k = 1 \quad \text{for axisymmetric flow}$$

The basic notation and coordinate scheme are shown in Figure 1, where U_∞ is a reference velocity and $u_e(x)$ is the velocity just outside the boundary layer. The coordinate system is a curvilinear one in which x is the distance along the surface measured from the stagnation point or leading edge, and y is measured normal to the surface. Within the boundary layer, the velocity components in the x - and y -directions are u and v , respectively. The body radius is r_0 .

The boundary conditions for equation (3) are

$$u(x,0) = 0 \quad (5a)$$

$$v(x,0) = 0 \quad (5b)$$

$$\lim_{y \rightarrow \infty} u(x,y) = u_e(x) \quad (5c)$$

Before equations (2) and (3) can be solved, they must be transformed to a coordinate system which removes the singularity at $x = 0$ and stretches the coordinate normal to the flow direction. First, these equations are placed in an almost two-dimensional form by the Probstein-Elliott transformation (Reference 18):

$$d\bar{x} = \left[\frac{r_0(x)}{L} \right]^{2k} dx \quad (6)$$

$$d\bar{y} = \left[\frac{r(x,y)}{L} \right]^k dy \quad (7)$$

where $r_0(x)$ is the body radius and $r(x,y)$ is a radius which accounts for the transverse curvature effect which will be subsequently discussed.

A stream function Ψ is defined that satisfies the continuity equation (2):

$$\frac{\partial \Psi}{\partial y} = r^k u \quad \frac{\partial \Psi}{\partial x} = -r^k v \quad , \quad \bar{\Psi} = \frac{\Psi}{L} \quad (8)$$

The resulting equations are transformed by the Levy-Lees transformation (Reference 19) in order to remove the singularity at $\bar{x} = 0$ and stretch the coordinates in the \bar{x} and \bar{y} directions. The Levy-Lees transformations are:

$$d\xi = \rho_\infty \mu_\infty u_e d\bar{x} \quad (9a)$$

$$d\eta = \frac{\rho_\infty u_e}{(2\xi)^{1/2}} d\bar{y} \quad (9b)$$

A dimensionless stream function, f , is introduced which is related to Ψ as follows:

$$\Psi = (2\xi)^{1/2} f(\xi, \eta) \quad (10)$$

Combining the Levy-Lees and the Probstein-Elliott transformations given above we have

$$d\xi = \rho_\infty \mu_\infty u_e \left[\frac{r_0(x)}{L} \right]^{2k} dx \quad (11a)$$

$$d\eta = \frac{\rho_\infty u_e}{(2\xi)^{1/2}} \left[\frac{r(x,y)}{L} \right]^k dy \quad (11b)$$

Introducing an eddy viscosity term to account for the Reynolds shear stress terms,

$$\epsilon \equiv - \frac{\overline{u'v'}}{\frac{\partial u}{\partial y}} \quad , \quad \epsilon^+ \equiv \frac{\epsilon}{U} \quad (12)$$

and a transverse curvature term t along with a pressure parameter term

$$\beta = \frac{2\xi}{u_e} \frac{du_e}{d\xi} \quad (13)$$

The momentum equation (3) then becomes, with $f' = u/u_e$,

$$\left[(1+t)^{2k} (1+\epsilon^+) f'' \right]' + ff'' + \beta \left[1 - (f')^2 \right] = 2\xi \left[f' \frac{\partial f'}{\partial \xi} - f'' \frac{\partial f}{\partial \xi} \right] \quad (14)$$

The boundary conditions given by equation (5) become

$$f(\xi, 0) = f_w = 0 \quad (15a)$$

$$f'(\xi, 0) = 0 \quad (15b)$$

$$\lim_{\eta \rightarrow \infty} f'(\xi, \eta) = 1 \quad (15c)$$

The momentum equation is then solved by a very efficient numerical scheme developed by Keller, (Reference 20) and applied to boundary layer calculations by Cebeci and Keller, (References 21 and 22).

Eddy viscosity equations. - The eddy viscosity concept is used to relate the time-mean fluctuating velocities to a mean velocity distribution as given in equation (12)

$$\epsilon \equiv - \frac{\overline{u'v'}}{\frac{\partial u}{\partial y}} \quad (12)$$

A two-layer model of the eddy viscosity within the boundary layer will be used as shown in figure 2.

In the inner region of the boundary layer an eddy viscosity model, based on Prandtl's mixing-length theory, is used:

$$\epsilon_1 = \ell^2 \left| \frac{\partial u}{\partial y} \right| \quad (16)$$

where ℓ , the mixing length is given by

$$\ell = K_1 Y \quad (17)$$

A modified expression for ℓ has been developed by Van Driest (Reference 23) to account for the viscous sublayer close to the wall. This modification is

$$\ell = K_1 Y \left[1 - e^{-(Y/A)} \right] \quad (18)$$

where A is given by

$$A = A^+ \frac{v_\infty}{N} \left[\frac{\tau_w}{\rho_\infty} \right]^{-1/2} \quad (19)$$

and

$$A^+ = 26.0 \quad (20)$$

$$N = \left[1 - 11.8 P^+ \right]^{-\frac{1}{2}} \quad (21)$$

$$P^+ = \frac{v_\infty u_e}{u_\tau^3} \frac{du_e}{d\xi} \rho_\infty \mu_\infty u_e \left(\frac{r_0}{L} \right)^{2k} \quad (22)$$

$$u_\tau = \left(\frac{\tau_w}{\rho_\infty} \right) \quad (23)$$

Now for axisymmetric flows the value of ℓ is replaced by

$$\ell = .4r_0 \ln \left(\frac{r}{r_0} \right) \left[1 - e^{-\frac{r_0}{A} \ln \left(\frac{r}{r_0} \right)} \right] \quad (24)$$

which is developed in reference 24. If transverse curvature effects are desired then

$$\begin{aligned} \frac{r}{r_0} &= \frac{r_0 + Y \cos \alpha}{r_0} = 1 + \frac{Y}{r_0} \cos \alpha \\ &= 1 + t \end{aligned} \quad (25)$$

$$\text{where } t = \frac{Y}{r_0} \cos \alpha$$

then ℓ becomes

$$\ell = .4r_0 \ln(1+t) \left[1 - e^{-\frac{r_0}{A} \ln(1+t)} \right] \quad (26)$$

The eddy viscosity in the outer region of the boundary layer is given by

$$\epsilon_0 = \alpha u_e \delta_k^* \quad (27)$$

where δ_k^* is the boundary layer displacement thickness defined by

$$\delta^* = \int_0^{n_\infty} \left[1 - \left(\frac{u}{u_e} \right) \right] dn \quad (28)$$

which in the transformed plane becomes

$$\delta_k^* = \left[\frac{L}{r_0} \right]^k \frac{(2\xi)^{\frac{1}{2}}}{\rho_\infty u_e} \int_0^{n_\infty} (1-f')(1+t)^{-k} dn \quad (29)$$

where

$$1+t = \left[1 + \frac{2L \cos \alpha}{r_0^2} \frac{(2\xi)^{\frac{1}{2}}}{\rho_\infty u_e} \int_0^{n_\infty} dn \right]^{\frac{1}{2}} \quad (30)$$

This relationship for ϵ_0 is the same for two-dimensional or axisymmetric flows as shown in Reference 24.

Low Reynolds number effects. - The calculation of turbulent boundary layers about two-dimensional and axisymmetric bodies must often be done at low Reynolds number, i.e., momentum thickness Reynolds number, R_θ , less than 6000. Most of the boundary layer methods including the one presented above are based on empirical data which were obtained at high Reynolds numbers. A correction term to account for low Reynolds numbers which was developed by Cebeci (Reference 25) based on prior work by Coles (Reference 26) is, therefore, applied to the outer eddy viscosity by varying the α in equation (27) with R_θ in the following manner.

$$\text{if } R_\theta < 425 \text{ then } \alpha = (.0168)(1.55) \quad (31a)$$

$$\text{if } R_\theta > 6000 \text{ then } \alpha = .0168 \quad (31b)$$

$$\text{if } 425 < R_\theta < 6000 \text{ then } \alpha = .0168 \left[\frac{1.55}{1+\Pi} \right] \text{ where}$$

$$\Pi = .55 \left[1 - e^{-0.243\sqrt{\gamma} - 0.298 \gamma} \right] \text{ and } \gamma = \left(r_\theta / 425 \right) - 1 \quad (31c)$$

Transverse curvature. - In developing the axisymmetric boundary layer equations a radius term is introduced as shown in equations (2) and (3). If the assumption is made that the body radius is very large compared to the boundary layer thickness then the radii in equations (2) and (3) reduce to the local body radius r_0 and the effect of the transverse (i.e.,

circumferential) curvature in the momentum equation is neglected. If, however, the body radius is small compared to the boundary layer thickness then the effect of the transverse curvature cannot be ignored and r must be a function of the distance into the boundary layer, y . The relationship between y , r_0 , and r is given by:

$$r = r_0 + y \cos \alpha \quad (32)$$

As observed in figure 3, α is simply the surface slope in the longitudinal direction. i.e.,

$$\tan \alpha = \frac{dr}{dx} \quad (33)$$

For slender cylinders where $\alpha = 0^\circ$,

$$r = r_0 + Y \quad (34)$$

The inclusion of the transverse curvature terms in the boundary layer equations is shown in References 24 and 27 to substantially improve the accuracy of the calculation of the local skin friction as well as the other viscous parameters.

Transition region effect. - The boundary layer method has the capability of calculating transition from laminar flow to turbulent flow in two different ways. The first approach is to use the transition point as a switching point between laminar and turbulent boundary layer calculations. At the transition point the turbulent boundary layer calculations are started by activating the eddy viscosity coefficient. In general, especially at low Reynolds numbers this approach can lead to errors as shown by Gebeci in Reference 28. The second approach which is available uses the intermittency factor given by Chen and Thyson (Reference 29) to modify the eddy viscosity equations to account for a region of transition. This modification was developed from the point of view of intermittent production of turbulent spots and is a further extension of Emmons' spot theory (Reference 30). The modification to be used is to multiply the inner and outer eddy viscosities equations (16) and (27) by the following parameter:

$$\gamma_{Tr} = 1 - e^{-Gr_o(x_{Tr}) \left[\int_{x_{Tr}}^x \frac{dx}{r_o} \right] \left[\int_{x_{Tr}}^x \frac{dx}{u_e} \right]} \quad (35)$$

$$G = \left(\frac{3}{3600} \right) \left(\frac{u_e^3}{v_\infty^2} \right) Re_{Tr}^{-1.34}$$

$$\text{where } Re_{Tr} = \frac{u_e x_{Tr}}{v_\infty}$$

The effect of this transition region correction can be seen in figure 4 which compares experimental data to theoretical calculations for local skin friction with and without the above correction on a two-dimensional ellipse. This transitional effect will be assumed to be the same for axisymmetric bodies.

Boundary layer transition location. - The location of boundary layer transition from laminar to turbulent flow can be either input to the boundary layer method or calculated internally within the program. The approach used to calculate the transition location is one developed for two-dimensional flow by Michel (Reference 31) and later verified by Smith (Reference 32). This method correlates the local momentum thickness Reynolds number, R_θ and the local distance Reynolds number, R_x , as shown in figure 5 which comes from Reference 32. The procedure used is to calculate the values of R_x and R_θ at each station and to compare them to the curve in figure 5. If the value of R_θ is less than the value of $R_{\theta TR}$ then transition has not been reached but if the value of R_θ is greater than $R_{\theta TR}$ then transition has occurred.

The above method was extended to axisymmetric flow by the use of Mangler's transformation. The parameters R_θ and R_x are calculated by the axisymmetric boundary layer routine and they are then transformed to two-dimensional values by the following relationships:

$$\theta_{2-D} = \left(\frac{r_o}{L} \right) \theta_{\text{AXISYMMETRIC}} \quad (36a)$$

$$x_{2-D} = \int_0^{x_{\text{LOCAL}}} \left(\frac{r_o}{L} \right)^2 (dx)_{\text{AXISYMMETRIC}} \quad (36b)$$

These values of θ_{2-D} and X_{2-D} are used to determine values of R_θ and R_x which can be used in conjunction with figure 5.

A study of transition location calculation for axisymmetric bodies was recently completed by Kaups (Reference 33). In this study empirical methods due to Granville, Hall and Gibbons, and the method of Michel presented above were compared to the stability analysis technique of Smith (Reference 32). It was determined that for flows where transition occurred in an adverse pressure gradient all of the above techniques predicted transition fairly accurately. For flows where transition occurred in favorable pressure gradients, only the method of Smith (Reference 32) gave satisfactory results as shown in figure 6 which is taken from Reference 33. The method of Smith, however, requires extremely lengthy computer calculation times which makes it undesirable for the iterative type of calculation presented in this report. Therefore, based on the results of Reference 33, the method of predicting transition in the present program should not be used for flows with very large Reynolds numbers where the transition location might occur in a favorable gradient, but rather the transition point should be input to the program.

Calculation Procedure

The viscous flow field about an axisymmetric body is simulated by calculating the inviscid flow about an equivalent "viscous" body which is formed by adding the boundary layer displacement thickness to the original body surface. This technique of defining the inviscid body has been used quite successfully for two-dimensional flows as shown in Reference 2 and has also been used for axisymmetric flows as presented in Reference 34. This equivalent body is formed by combining the previously discussed geometry routine, potential flow method, and boundary layer method under control of the axisymmetric design and analysis method computer program known as ADAM.

Given the desired axisymmetric configuration and flow conditions, the ADAM program utilizes these sections, as shown in figure 7, in the following iterative manner:

1. Precise geometry definition for input into the potential flow program.

2. Calculation of the exact nonlinear potential flow for specified geometry and flow conditions.
3. Calculation of the viscous flow characteristics based on the results of the potential flow program.
4. Addition of boundary-layer displacement thickness to the basic geometry for each element.
5. Recalculation of the pressure distribution utilizing the potential flow program, based on the redefined geometry.
6. Recalculation of viscous flow field based on recalculated pressure distribution from redefined geometry, if desired.
7. Possible iteration of the above scheme; the degree to which this is required is presented in the subsequent discussion on correlations with experimental data.

The above technique must be modified when the boundary layer separates or when the local body radius approaches zero at the trailing edge of the body. When the dimension of the local body radius approaches zero at the trailing edge, the boundary layer equations become invalid since the $1/r$ term in equation (3) approaches infinity. When this occurs, the boundary layer results are ignored from this point downstream to the trailing edge. The assumption is then made that the boundary layer displacement area at the point where

$$\delta^* \cos \alpha = r_o \quad (37)$$

is defined by

$$\text{DAREA} = \pi \left\{ \left(r_{op} + \delta^* \cos \alpha_p \right)^2 - r_{op}^2 \right\} \quad (38)$$

where p refers to the point where equation (37) is first satisfied. This displacement area is then considered to remain constant from the point p to the trailing edge. The new "viscous" body coordinates in this region are then defined by

$$y_{\text{new}} = \left\{ \frac{\pi r_o^2 + \text{DAREA}}{\pi} \right\}^{\frac{1}{2}} \quad (39)$$

The second problem area occurs when the boundary layer separates from

the body creating a separation bubble. This bubble must be accounted for in the creation of a "viscous" body if the flow about this configuration is to be predicted accurately. The simplest technique of modeling this separation bubble is to assume that the flow leaves the surface parallel to the free-stream direction, producing a cylindrical wake shape as shown in figure 8. This approach, however, gives decelerations in the flow at the junction of the body with the cylinder as shown in figure 9, which do not exist in the real flow field. To minimize this problem, a circular arc is used to fair the body into the separated cylinder.

This circular arc is defined by passing a circle through the last three "viscous" body coordinates defined prior to the separation point. The radius of this circle is then used to create a circular arc which is tangent to the "viscous" body at the point of separation. The center of this arc is then defined according to whether the surface slope of the body at separation is positive or negative.

If the surface slope is positive then the center is taken as the center of the circle passed through the three points as defined above. This center is defined by

$$x_c = x_{sep} + R \sin \left[\tan^{-1} \left| \frac{dy}{dx} \right| \right] \quad (40a)$$

$$y_c = y_{sep} - R \cos \left[\tan^{-1} \left| \frac{dy}{dx} \right| \right] \quad (40b)$$

where R = Radius of the circle

$\frac{dy}{dx}$ = Surface slope at separation

This arc is then used from the point of separation to either the end of the body or to the maximum point on the arc, where $dy/dx = 0$, as shown in figure 10a. If the maximum point of the arc occurs before the trailing edge of the body is reached then a cylinder is defined which extends from the maximum point of the arc to the trailing edge.

If the surface slope is negative then the circular arc is defined such that the center is located above the body. The center is then defined by

$$x_c = x_{sep} + R \left[\sin \tan^{-1} \left| \frac{\partial y}{\partial x} \right| \right] \quad (41a)$$

$$y_c = y_{sep} + R \left[\cos \tan^{-1} \left| \frac{\partial y}{\partial x} \right| \right] \quad (41b)$$

This arc is then used from the point of separation to either the end of the body or to the minimum point on the arc, where $dy/dx = 0$, as shown in figure 10b. If the minimum point of the arc occurs before the trailing edge of the body then a cylinder is defined which extends from the minimum point of the arc to the trailing edge of the body.

The above separated wake model has been derived from intuitive considerations rather than from first principals. It does, however, provide reasonable results, as will be shown in the subsequent discussion.

The base drag coefficient for blunt axisymmetric bodies is calculated using the method of Hoerner, reference 35. This approach is based on the assumption that the flow field behind a blunt base is basically a jet pump, in that, air flowing around the body leaves the trailing edge forming a cylindrical jet which attempts to pump away the stagnated air in the base region. However, since there is no air to replace this stagnated air, the pumping mechanism can only reduce the static pressure acting on the base. The effectiveness of this jet pump mechanism is controlled by the boundary layer thickness at the base since this region of lower momentum flow acts as a buffer between the stagnated air behind the base and the flow in the jet. Since the boundary layer thickness is directly related to the skin friction on the body, C_f , Hoerner used C_f to correlate with the base drag to develop an empirical approach to determine base drag. Figure 11 shows the correlation obtained by Hoerner for bodies whose base area is the same as the maximum area. This curve is represented by

$$C_{D\text{BASE}} = .029/\sqrt{C_{f\text{Forebody}}} \quad (42)$$

where the coefficients are based on the base area. Thus, once the skin friction on the forebody has been calculated in the boundary layer programs, then the base drag can be determined by equation 42.

This equation must be modified for boat-tailed bodies, that is, bodies whose base area is less than their maximum area. The mechanics of the base drag for these configurations do not change, but the calculation must take into account the reduced base area. This effect is taken into account by the following relationship:

$$C_{D_{BASE}} = C_{D_{BASE}} \cdot \left(\frac{d_{BASE}}{D_{MAX}} \right)^2 \quad (42a)$$

and

$$C_{f_B} = C_{f_B} \cdot \left(\frac{D_{MAX}}{d_{BASE}} \right)^2 \quad (43b)$$

(BOAT TAIL)

so

$$C_{D_{BASE}} = \frac{.029}{\sqrt{C_{f_B}}} \cdot \left(\frac{d_{BASE}}{D_{MAX}} \right)^3 \quad (43c)$$

BOAT TAIL

A comparison of results calculated by the above method in ADAM with experimental force data from reference 35 is presented in figure 12. One of these cases is for a boat-tailed body and the other for a body whose base area is also the maximum area.

The experimental data used for this comparison as well as the configuration used for the analytical calculations are both subject to some discussion. The experimental base drag, taken from Figure 4 of Reference 35, originally came from an old German report which is not readily available. These base drag values were obtained from both force measurements and pressure measurements which unfortunately do not agree. Therefore, since it was felt that the force measurements were the more accurate, they were used in the comparison shown in Figure 12. In addition, no good definition of the configuration tested was available, therefore, the geometry used in the ADAM analysis was taken from the schematics shown in Reference 35. In light of these uncertainties the comparison presented in Figure 12 is fairly good in that even though the levels are different, the trends are the same. It should be noted that this comparison was used only because there is a singular lack of experimental data for blunt based axisymmetric bodies at low subsonic Mach numbers.

EXPERIMENTAL CORRELATIONS

Experimental results from three different configurations were selected to establish the extent of validity of the method presented in this report. These geometries consisted of a high fineness ratio body of revolution, and a sphere in both subcritical and supercritical flow regimes. These correlations, while limited to some extent by the scope of the present effort, do represent a wide range of axisymmetric flow conditions.

The body of revolution chosen was tested in the low speed wind tunnel at the Douglas Aircraft Company, (Reference 36), and is shown in figure 13. This model was composed of three sections; an elliptical nose section, a cylindrical control section, and a parabolic afterbody. The calculation done for this configuration used the wind tunnel flow properties, namely, $U_{\infty} = 71.628$ M/Sec (235 Ft/Sec), $T_{\infty} = 288.3^{\circ}\text{K}$ (519.0°R) and $R_L = 10.05 \times 10^6$. Boundary layer transition was fixed on the model and in the calculation at .03048 meters (1.2 inches) from the nose. This model was relatively large for the wind tunnel in which it was tested; wall effects, not accounted for in the original data reduction, were present. To correct for this, the model was run in the potential flow program in the presence of the wind tunnel walls as shown in figure 14. The effect of including the walls in the calculation is shown in the inviscid pressure distributions of figure 15. The final results for this configuration are shown in figure 16 where the calculated "viscous" results are compared to experimental data. The inviscid distribution is also shown for reference. In this particular case no separation occurred and so only one iteration, that is, two potential flow solutions and two boundary layer solutions, was necessary. The calculated "viscous" results agree very well with the experimental values except in the region of the nose. This discrepancy is not due to the calculation method, but rather is due to the model being too long for the wind tunnel test section resulting in the nose being in a different static pressure field than the rest of the body. The overall effect of viscosity on this configuration is seen to be small except in the region of the trailing edge. The body is so slender in this region that the boundary layer equations are no longer valid so the technique described in the calculation procedure was used to modify the viscous body. The results show a pressure oscillation

in this modified region which is due to an unsmooth curvature distribution. However, the level of these pressures agree quite well with the experimental values.

The second case considered was that of a sphere in the supercritical flow regime, i.e., $R_D = 1 \times 10^6$. Since the boundary layer transition was forced to occur at an $X/D = .65$, there were regions of both laminar and turbulent flow present. The experimental data for this case were taken from references 37 and 38. The freestream velocity assumed for this case was 47.85 M/Sec (157 Ft/Sec). Figure 17 shows the sphere with the "viscous" body superimposed and figure 18 presents a comparison between the calculated "viscous" solution and experimental data. Note that while the calculated pressure distribution is in reasonably good agreement with the experimental values, the calculated separation point is .07 diameters further downstream than the experimentally measured value. The inviscid and "viscous" solutions for the local skin friction coefficient, C_f , are presented in figure 19. The "viscous" solution shown is the fourth iteration, i.e., the fifth potential flow solution, and appears to be the best solution possible for this configuration with the technique being used in the present method to simulate flow separation.

The last correlation to be presented is for the flow about a sphere in the subcritical regime, i.e., $R_D = 1 \times 10^5$, which is a purely laminar case. The experimental data is again taken from Reference 37. The freestream velocity for this case was assumed to be 4.785 M/Sec (15.7 Ft/Sec). The calculated "viscous" body is shown in figure 20 while a comparison of the "viscous" pressure distribution to experimental data is shown in figure 21. The calculated "viscous" pressures are in close agreement with the experimental values with some slight over-prediction in the separated region. The calculated separation point is only .03 diameters further downstream than the experimental value which is excellent considering the large effect that viscosity has on this configuration. Figure 22 presents the inviscid and "viscous" solutions for the local skin friction coefficient for this case.

CONCLUDING REMARKS

A method has been presented for the computation of the viscous flow field about axisymmetric bodies at zero angle of attack in incompressible flow. This computing program requires only the specified body geometry and desired flow conditions as input. The appropriate theory has been discussed and correlations between theoretical and experimental results presented.

The flow field about axisymmetric bodies at zero angle of attack with no flow separation is well defined and can be computed accurately by the present method. When flow separation occurs, the flow field is no longer amenable to analytical treatment. Currently, methods do not exist to calculate the flow field within a separated region; it is therefore necessary to resort to empirical methods to account for flow separation. Since there is almost a complete lack of experimental data concerning the behavior of separated regions, any empirical methods must necessarily be somewhat crude. The most sophisticated model for separation currently available is due to Jacob (References 39 and 40) and is strictly for two-dimensional airfoils. An unsuccessful attempt was made in Reference 41 to adapt Jacob's approach to axisymmetric configurations. The conclusions of Reference 41 indicated that the assumed boundary conditions needed to be modified if this approach was to be used for axisymmetric flow. It is proposed that the Douglas-Neumann program be used to pursue this approach at modeling separation. This potential flow program is ideal for attempting to use Jacob's technique since it already has the ability to specify a non-uniform flow distribution over all or part of a configuration; therefore, only suitable boundary conditions would have to be added to the program. It is felt that this approach can be successful in modeling separation if care is taken in developing the distribution of non-uniform velocity as well as specifying the proper boundary considerations.

The further extension of this model to the calculation of flow about axisymmetric bodies at angle of attack is also possible. The potential flow routine contained in the present method has the capability of predicting the flow field about non-lifting bodies at angle of attack by combining the streamflow and the crossflow solutions. The boundary layer analysis would require the replacement of the routine in the present method by a three-dimensional

technique, which is currently not available. However, it is felt that a good approximation to the boundary layer calculations can be made by the small crossflow program of Reference 42.

One area of primary concern in extending the method to include an angle of attack capability is the determination of the separation line about the body. The present method of predicting separation for two-dimensional bodies and for axisymmetric bodies at zero angle of attack is to find the location where the skin friction goes to zero. It has been shown in several studies, including those reported in References 43 and 44, that this condition does not apply in three-dimensional flows because the skin friction along a separation line is not necessarily zero. Therefore, some method of determining the separation line for axisymmetric bodies at angle of attack must be developed. It is proposed that the present method could be extended to calculate the "viscous" flow about axisymmetric bodies at angle of attack when no flow separation is present. This method could then be used to assist in the development of a procedure for determining the separation line location. Once the location of the separation line is known then a model could be developed for analyzing the viscous flow about the separated body. The development of such procedures is not a simple task and considerable effort would have to be expended; but the reward for accomplishing this task is an advance in the ability to calculate the real flow about arbitrary three-dimensional bodies which is our ultimate goal.

APPENDIX A

INPUT INFORMATION FOR ADAM COMPUTER PROGRAM

This part of the report contains the necessary information to input data to the ADAM computer program. The input data is broken into three sections: smoothing, potential flow, and viscous flow. These sections can be used together in the iterative fashion described in the main text, or the potential flow and viscous flow sections may be used independently. A detailed card-by-card description of all input quantities is given followed by a set of input forms which can be used to facilitate the loading of the input data into the program.

Input Instructions

The Adam program requires one system control card followed by the required sets of data cards for each program option to be executed. The sets of data furnished must be in the same order as the options are specified on the system control card. If an iteration is desired the system control card is repeated along with the necessary other data cards.

The general scheme used in describing the input data is shown below:

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
Column -			Column indicates the starting position on the card for each data field.
Code -			The "code" gives the FORTRAN name used in the read statement by the program.
Routine -			"Routine" indicates the subroutine where the data is read.
Format -			The parameter "FORMAT" which is given right under the routine name, indicates the FORTRAN format of the data read statement field. The parameter I5 would indicate that the parameter is an integer in a field that is 5 columns wide. Integers should be punched on the right side of the field (right justified). The parameter F10.0 would indicate a fixed point number punched with a decimal point (i.e., -12.354). The number may be punched anywhere in the field indicated irrespective of the decimal point location indicated by the format. The parameter E12.6 would indicate a floating point number punched with a decimal point (i.e., 5.0×10^6). The number must be punched to the right of the field in the manner 5.OE+06.
Explanation -			The description of the input data is given under "explanation".

SUSTEM CONTROL DATA CARD (This card must be the first card in the data deck)

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
4	IGEOM	MAIN I1	Smoothing option flag =0 no smoothing is desired =1 smoothing is desired
8	INEUM	MAIN I1	Potential flow option flag =0 No potential flow solution is desired =1 Potential flow solution is desired
12	IBOUND	MAIN I1	Boundary layer option flag =0 No boundary layer solution is desired =1 Boundary layer solution is desired
16	ITER	MAIN I1	"Viscous" body formation flag =0 No "viscous" body is formed =1 "Viscous" body is formed
17-20	IFINSH	MAIN I4	Termination Flag =0 Another case expected =9999 Program will stop after exer- cising all options specified above

SMOOTHING SECTION

These cards required if IGEOM = 1 on system control card. This section is used to smooth body geometry data before it is input to the potential flow program.

Smoothing Control Card

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
2	NPTS	SMOOTH I3	Number of input data points for this configuration. NPTS must be ≤ 100
8	ITAPE	SMOOTH I1	Data source flag =0 Data input on unit 5 (card input) ≠0 Data input on unit 1. This is used for a case where a "viscous" body generated by the iteration procedure is being read.

Geometry Data Input Cards

These cards are input only if ITAPE = 0.

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
<u>x-coordinate cards</u>			
1-10	x(1)	SMOOTH	x-coordinates starting at the leading edge and proceeding along the upper surface to the trailing edge. Input 6 x-values on each card. The numbers of x-values must be equal to NPTS.
11-20	x(2)	6F10.0	
21-30	x(3)		
etc.			
<u>y-coordinate cards</u>			
1-10	y(1)	SMOOTH	y-coordinates to correspond to the above x-locations. y-values must be positive. Input 6 values per card.
11-20	y(2)	6F10.0	
21-30	y(3)		
etc.			

POTENTIAL FLOW SECTION

These cards required if INEUM = 1 on system control card. The input geometry for this program may be obtained from the geometry storage unit (10) as generated by the smoothing section, or it may be input directly on unit 5. Thus, this program may be operated as a separate entry if so desired. The program saves the geometry data element midpoints with the corresponding pressure coefficients on unit 3 for input to the boundary layer routine and it saves the basic non-dimensional input Neumann coordinates on unit 1 for use if a "visous" body is desired.

Title Card

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
1	HEDR	PART1 10A6	Title of case. May be any characters input in the first 60 columns of card:
63	CASE	PART1 I6	Case number
77	PSF	PART1 I6	Additional identifier for this case.

Flag Card

Card columns 1-30 when punched with any non-zero integer, activate flags that indicate the following:

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
1	NB	PART1 I1	The number of bodies input. Normally set equal to 1. $1 \leq NB \leq 5$
2	NNU	PART1 I1	The number of non-uniform onset flows. Normally set equal to 0.
3	FLG03	PART1 I1	Axisymmetric flow flag. =0 No axisymmetric stream-flow solution calculated. =1 Axisymmetric streamflow solution is calculated Normally set equal to 1

Flag Card (Continued)

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
4	FLG04	PART1 I1	Cross flow flag. =0 No cross flow solution is calculated =1 Cross flow solution is calculated Normally set equal to 0
5	FLG05	PART1 I1	Off-body point flag =0 No off body points input =1 Off body points are input This flag allows the velocity at points off the body surface to be determined.
6	FLG06	PART1 I1	Basic data formation flag =0 A full case will be done =1 The basic data, i.e., midpoints, normals, etc. will be formed and printed. No velocities will be calculated.
7	FLG07	PART1 I1	Ellipse generator option =0 Body coordinates will be input =1 An ellipse is generated using data input later. No body coordinates are input
8	FLG08	PART1 I1	Matrix print flag =0 Coefficient matrices are not printed. =1 Coefficient matrices will be printed. Normally set equal to 0
11	FLG11	PART1 I1	Perturbation velocity flag =0 Normal case =1 No onset flow used. Only perturbation velocities are calculated.
12	FLG12	PART1 I1	Potential matrix solution * =0 Normal case =1 A potential matrix is solved

Flag Card (Continued)

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
13	FLG13	PART1 I1	Matrix solution flag =0 No matrix solution done =1 Matrix solution performed Normally set equal to 1.
14	FLG14	PART1 I1	Prescribed tangential velocity flag * =0 Normal case =1 Tangential velocities are specified
15	FLG15	PART1 I1	Strip ring vorticity flag * =0 Normal case =1 A vorticity distribution is formulated.
16	FLG16	PART1 I1	Axisymmetric uniform flow flag =0 Normal case =1 Axisymmetric uniform flow solution is omitted Normally set equal to 0.
17	FLG17	PART1 I1	Crossflow uniform flow flag =0 Normal case =1 Crossflow uniform flow solution is omitted. Since FLG04 is normally = 0 then so is FLG17 normally set equal to 0.
18	FLG18	PART1 I1	Surface vorticity flag * =0 Normal case =1 Surface vorticity is generated.
19	FLG19	PART1 I1	Prescribed vorticity Flag * =0 Normal case =1 A prescribed vorticity is input
20	FLG20	PART1 I1	Total vorticity flag * =0 Normal case =1 Total vorticity calculated

Flag Card (Continued)

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
21	FLG21	PART1 I1	Extra crossflow flag * =0 Normal case =1 Extra crossflow option used
22	FLG22	PART1 I1	Generated boundary condition flag * =0 Normal case =1 Boundary conditions generated
23	FLG23	PART1 I1	Ring wing option flag * =0 Normal case =1 Ring wing option used
28-29	NIN	PART1 I2	Tape input flag =0, 10 Data input on unit 10 from smoothing program =5 Data input from unit 5 (card input)
30	ITER	PART1 I1	Iteration tape flag =0 x/c, y/c transformed data saved on unit 15 =1 x/c, y/c transformed data not saved. This flag is necessary because for a "viscous" body to be formed, the coordinates of the original unmodified body must be saved. Therefore, for the first case set ITER = 0. For subsequent iterations we do not want to use the modified bodies to form new bodies so set ITER = 1.

* These flags are for special options which are discussed in the main text. They are never used for a normal axisymmetric calculation. Therefore, set them equal to zero.

Chord Card

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
1	CHORD	PART1 F10.0	Reference chord length used to non-dimensionalize x and y coordinates
11	MN	PART1 F10.0	Mach number (MN < 1.0) use to approximate effect of compressibility (Gothert's rule)
21	TCNST	PART1 F10.0	This is a constant which is used for the value of the tangential velocity if this option is desired.

Body Transformation Card

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
8	NN	BASIC1 I3	The number of input points on this body. $NN \leq 100$
11	MX	BASIC1 F10.0	A factor used to multiply all x-coordinates. MX is assumed equal to 1 if no value is input.
21	MY	BASIC1 F10.0	A factor used to multiply all y-coordinates. MY is assumed equal to 1 if no value is input.
31	THETA	BASIC1 F10.0	An angle (in degrees) through which all points of a body are to be rotated about the origin in the clockwise direction.
41	ADDX	BASIC1 F10.0	A constant to be added to all x-coordinates
51	ADDY	BASIC1 F10.0	A constant to be added to all y-coordinates

Body Control Card

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
10	BDN	BASIC1 I1	Body sequence number. This program will handle up to 5 bodies.
20	SUBKS	BASIC1 I1	Subcase Flag. =0 Normal case =1 Use unmodified coordinates of the previous case.
30	NLF	BASIC1 I1	Non-lifting flag =0 Body is non-lifting (normal case) =1 Body is lifting (this is used in special option)
31	XE	BASIC1 F10.0	Value of major semi-axis for use by ellipse generation option.
41	YE	BASIC1 F10.0	Value of minor semi-axis for use by ellipse generation option Note: if XE = YE a sphere will be formed.

Geometry Data Cards

The body geometry data cards are included only if the input parameters NIN = 5 and FLG07 = 0 on the flag card. If NIN = 0 or 10 then the data is read from unit 10. If NIN = 5 and BDN = 0, then the following cards contain the x-y coordinates of off-body points instead of x-y geometry data. The number of either geometry data point or off-body points must be equal to NN.

x-Coordinate cards (six values per card)

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
1	TX1(1)	BASIC1 6F10.0	x-coordinates of body input from leading to trailing edge.
11	TX1(2)		
21	TX1(3)		

y-Coordinate cards (six values per card)

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
1	TY1(1)	BASIC1 6F10.0	y-Coordinates of body which correspond to the x-values above. y values must be positive.
11	TY1(2)		
21	TY1(3)		
	etc.		

NOTE: Each body input, including the off body points, requires the body transformation card, the body control card, and may also require the geometry data cards depending on the input flags. This is the stopping place for a normal axisymmetric case. The following cards are input only if one of the special options is required.

Tangential Velocity Data (six values per card)

These cards are input only if FLG14 \neq 0 and TCNST = 0.0

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
1	TG(1)	BASIC1 6F10.0	Specified tangential velocities at element midpoints.
11	TG(2)		
21	TG(3)		
	etc.		

Non-uniform Flow Cards (six values per card)

These cards are input only if NNU \neq 0.

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
6	NUM	BASIC2 I5	Non-uniform flow identification number.

Non-uniform Flow Cards (Continued)

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
19	MSF	BASIC2 I2	<p>If MSF = 0 the flow velocities N_o, T_o will be used for the axisymmetric case only.</p> <p>If MSF = 1 the flow velocities N_o, T_o will be used for the cross flow case only.</p> <p>If MSF > 1 the flow velocities will be used for both axisymmetric and cross flow cases.</p>
21	TYPE	BASIC2 F10.0	<p>Flag which specifies the type of input flow velocities at each mid-point. If TYPE > 0.0, the velocities are input as x & y components.</p> <p>If TYPE = 0.0 the velocities are input as normal & tangential components.</p> <p>If TYPE < 0.0 the automatic generation of the flow due to a rotating body is used.</p>
31	FG	BASIC2 F10.0	<p>Constant used by the flow generator. Type must be less than 0.0.</p>

The following cards are input only if NNU \neq 0 and TYPE \neq -1.0.

Normal velocity cards (six values per card)

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
1	NO(1)	BASIC2	<p>This is either the x or normal velocity component depending on the value of type above. These values must be in sequence with the coordinate data. If the x component is input it is defined as positive to the right. If the normal velocity is input it is positive if it is to the interior of the body. NN-1 values are input.</p>

Tangential Velocity Cards (six values per card)

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
1	TO(1)	BASIC2 6F10.0	This is either the y or tangential velocity component depending on the value of type above. These values must correspond to the NO values above. If the y component is input it is defined as positive if it is orientated upwards. If the tangential velocity is input it is positive if the flow field is to the left of the vector representing the tangential velocity.

VISCOUS FLOW SECTION

These cards required if IBOUND = 1.

BOUNDARY LAYER PROGRAM

The geometry and pressure distribution data required by this program may be input directly on cards (Unit 5), or read from the data save unit (Unit 3) as generated by the Neumann program.

HEADER CARD

This card is supplied purely for description purposes.

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
1-60	TITLE	INPT 15A4	Description of input
61	CASE	INPT A4	Case number

Flag Control Card

This card contains flags which control the type of flow to be considered and the form of the input.

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
1	NXT	INPT I4	The number of the x-station where the flow goes turbulent measured from the stagnation point (i.e., the leading edge for axisymmetric bodies at zero angle of attack) if transition is to be calculated by the program set NXT to be one greater than the number of points input.
5	LG16	INPT I1	Transition flag =0 Boundary layer transition point is input =1 Boundary layer transition point is computed. Set NXT to be greater than number of points input.

Flag Control Card (Continued)

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
6	LG17	INPT I1	Transition control flag =0 Transition is instantaneous =1 Transition is gradual (transitional region used)
7	LG18	INPT I1	Transverse curvature flag =0 No transverse curvature correction used. =1 Transverse curvature corrections applied.
8	LG32	INPT I1	Print control flag =0 Print using long format (with velocity profiles) =1 Use short printout (no velocity profiles)
9	LG26	INPT I1	Velocity input control flag =2 Velocity ratio (U_e/U_∞) is input =3 Pressure coefficient (c_p) is input.
10	LG40	INPT I1	Unit input flag for geometry and velocity data. =0 Data read from unit 3 as generated by the potential flow program. #0 Data read from cards (unit 5)
11	LG41	INPT I1	System of units FLAG =0 English system of units =1 Internation system of units

Flow Condition Card

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
1	TI	INPT F10.0	Reference static temperature used to compute the reference fluid properties. If TI is input as zero then TI is set equal to either 288.33°K or 519°R depending on FLAG LG41

Flow Condition Card (Continued)

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
11	RMI	INPT F10.0	Reference or free-stream Mach number. =0.0 UI is input next ≠0.0 UI is computed from RMI.
21	UI	INPT F10.0	Reference or free-stream velocity =0.0 M_∞ is input above ≠0.0 M_∞ input as zero above.
31	FK	INPT F10.0	Flow index =0.0 2-D flow assumed =1.0 Axisymmetric flow assumed
41	RL	INPT F10.0	Chord or reference length
51	RI	INPT E12.0	Reynolds number/foot $R_c / \ell = \frac{U_\infty}{\nu}$ If CHORD = 1.0 then RI must be Reynolds number based on CHORD. NOTE: The input of either Mach number or freestream velocity is for convenience only. This program is entirely incompressible.

Radius card

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
1	ROMAX	INPT F10.0	Maximum radius of body. This is used to obtain frontal area for skin friction calculation.
11	DETA1	INPT F10.0	Initial step size of boundary layer velocity profile grid. For a case which contains turbulent flow set DETA1 = .005.

Radius card (continued)

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
21	VGP	INPUT F10.0	VGP is the growth factor for the boundary layer velocity profile grid; for cases with turbulent flow set equal to 1.14. NOTE: For laminar cases the boundary layer velocity profile grid may be made constant if VGP = 1.0 is input. However, if this is done the minimum value of DETAI that can be input is approximately .10. This can be calculated if the value of the transformed boundary layer thickness, ETAINF, is known. Then DETAI becomes $DETAI = \frac{ETAINF}{100}$

Geometry-Pressure Distribution Cards

These cards input only if LG40 ≠ 0.

Point Number Card

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
1	NXM	INPT I4	Number of data points to be input. Maximum of 100 points allowed.

x-Coordinate Data Cards

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
1	XS(1)	INPT	x-coordinate points input from leading to trailing edge input 6 points per card. Number of points = NXM
11	XS(2)	6F10.0	
21	XS(3)		

etc.

y-Coordinate Data Cards

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
1	YS(1)	INPT 6F10.0	y-coordinate points corresponding to x-coordinates above input 6 points per card.

y-Coordinate Data Cards (continued)

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
11	YS(2)		
21	YS(3)		
etc.			

Pressure Distribution Cards

<u>Column</u>	<u>Code</u>	<u>Routine Format</u>	<u>Explanation</u>
1	UE(1)	INPT 6F10.0	Velocity-pressure-distribution points corresponding to x-points input above input 6 points per card.
11	UE(2)		
21	UE(3)		If LG26 = 2 u_e/U_∞ input LG26 = 3 c_p input
etc.

APPENDIX B

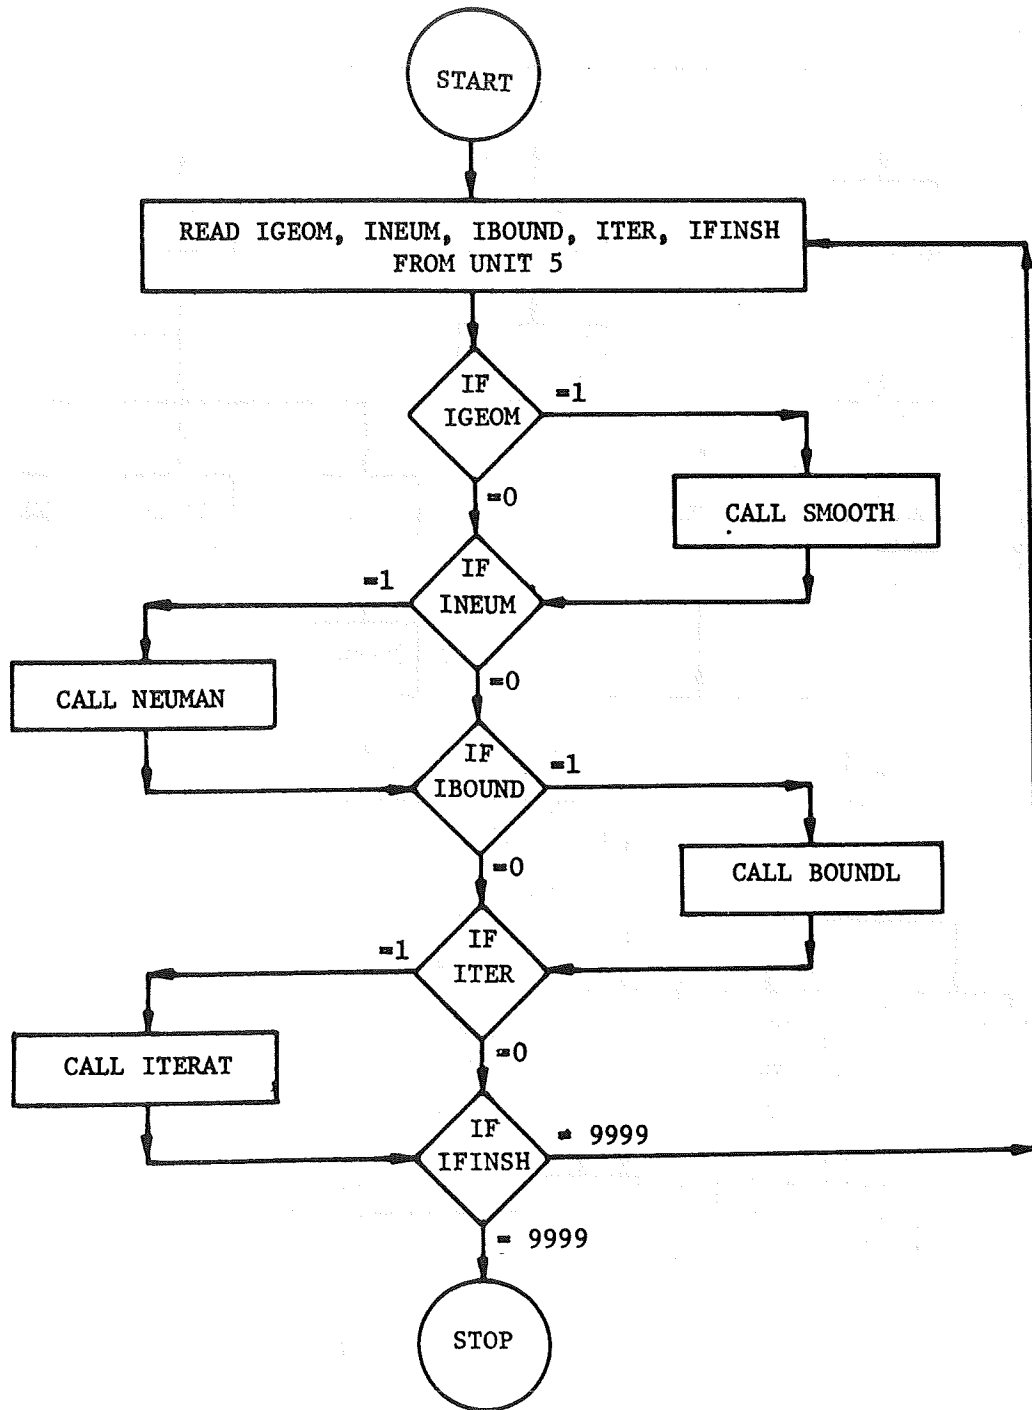

CONTROL INFORMATION FOR ADAM COMPUTER PROGRAM

This part of the report contains the necessary control information to operate this program on a computer system. This section contains the overlay structure as well as flow charts of the main subroutines including input flow information. Also, the various data sets used between main programs are described.

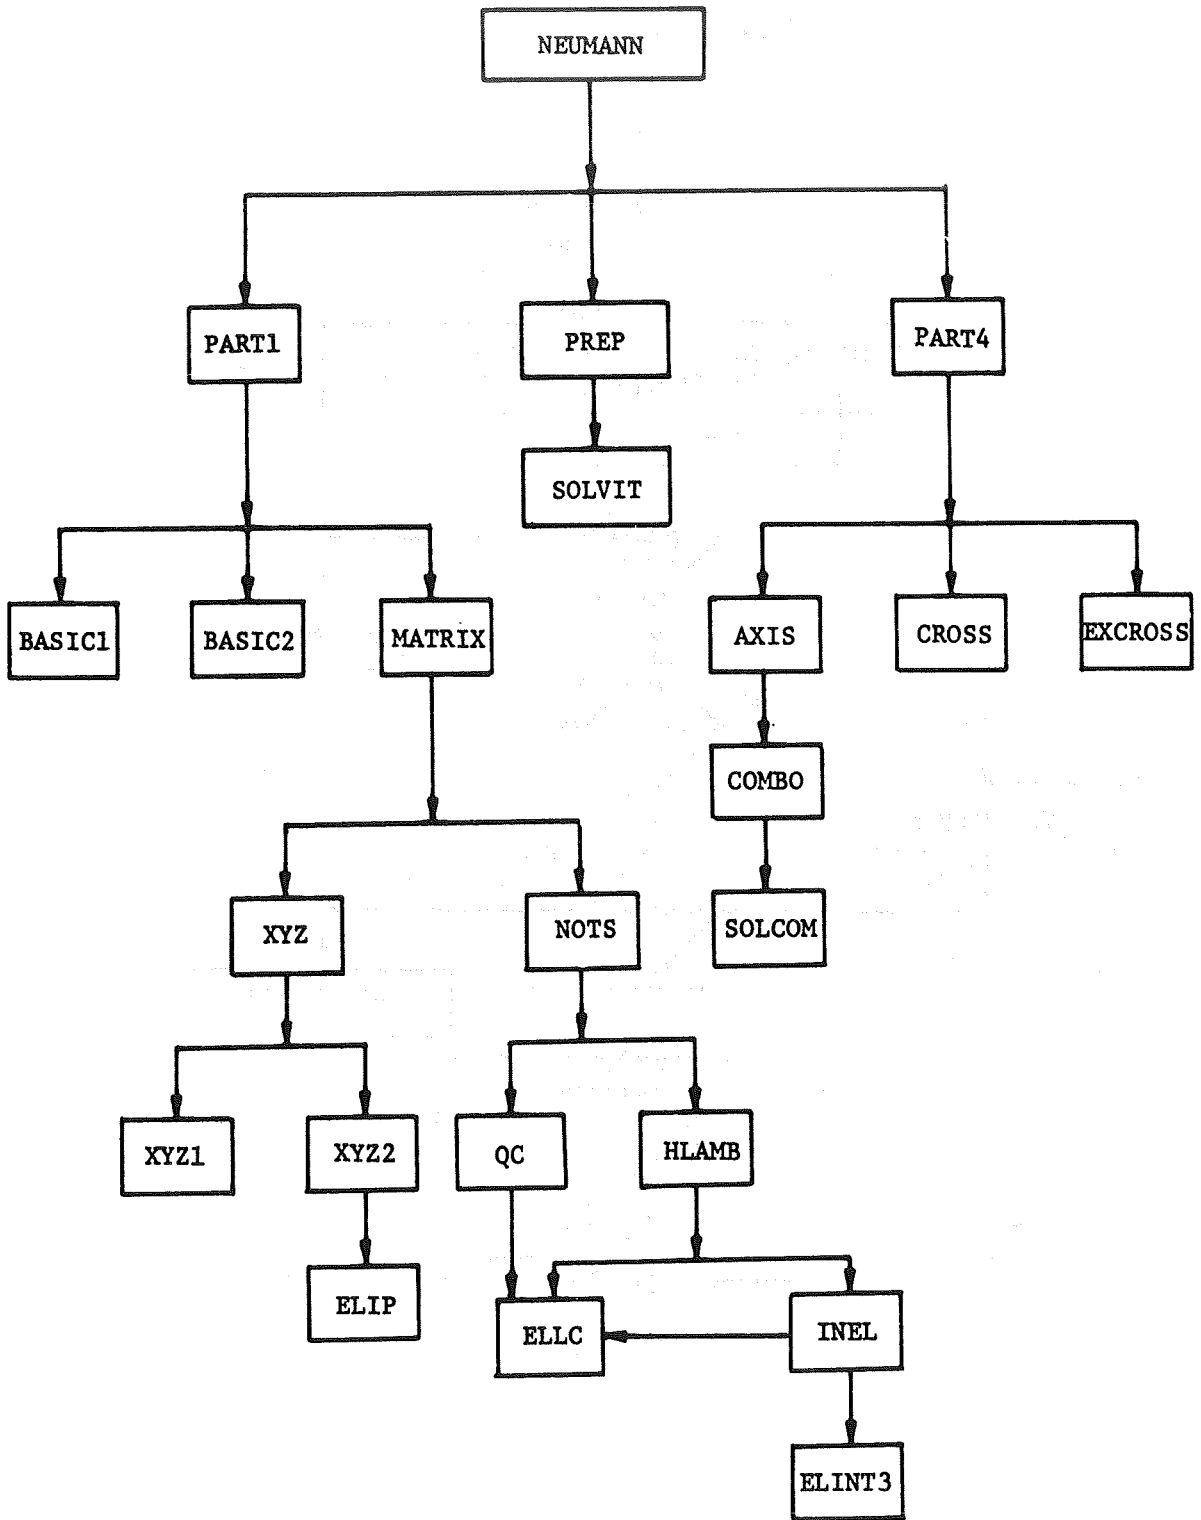

OVERLAY STRUCTURE OF ADAM

BASIC FLOW CHART FOR SUBROUTINE BOUNDL (CONTINUED)

BASIC FLOW CHART FOR SUBROUTINE INPT

The following is a description of the output symbols from the various sections of the ADAM computer program:

NEUMANN POTENTIAL FLOW SUBPROGRAM

<u>SYMBOL</u>	<u>DESCRIPTION</u>
ADDED MASS	$\Sigma 2\pi \cdot \text{Phi} \cdot V_n \cdot ds$
AJK	Influence coefficients W_{jk} resolved parallel to the outward normal of the element. Output only if $\text{FLG08} = 1$.
ADDX	Constant which is added to all X-coordinates of a particular body. Value printed out for each body.
ADDY	Constant which is added to all Y-coordinates of a particular body. Value printed out for each body.
BJK	Influence coefficient W_{jk} resolved parallel to the tangent direction of the element.
BODIES	Number of bodies in system, same as NB input on flag card.
BODY NO.	Number of this particular body. This parameter input on body control card.
CHORD	The reference chord for the system.
COSA	The cosine of DALPHA
CP	The pressure coefficient on a body element.
DALPHA	The change in angle between consecutive elements of a body. (degrees)
DELTAS	The length of a body element.
MACH NO.	Mach number used in Gothert's transformation.
MX	The factor by which all X-coordinates are multiplied for one body. Input on body transformation card.
MY	The factor by which all Y-coordinates are multiplied for one body. Input on body transformation card.

<u>SYMBOL</u>	<u>DESCRIPTION</u>
N	Velocity normal to a surface element, this is a measure of how well the boundary condition of zero normal velocity is satisfied.
NN	The number of geometry data points for a given body. This is input on the body transformation card.
NNU	The number of non-uniform onset flows to be considered.
PHI	Value of potential on each surface element.
PSF NO.	Identification for this case..
SIGMA	Source density on each surface element.
SINA	Sin of DALPHA
SUM(T) DELTA(S)	This is the summation of T multiplied by Deltas up to each element midpoint.
SUMDS	Summation of Deltas, surface distance around the body.
TCNST	Constant value of tangential velocity used in special option.
THETA	The angle through which a body is to be rotated about the origin in a clockwise direction.
TI	The velocity at each midpoint.
VOLUME	The volume of the body being analyzed. (calculated by Neumann)
X	The input X-coordinate defining the body surface, or off-body X-coordinates.
XE	The value of semi-major axis used in ellipse generation option.
Y	The input Y-coordinates defining the body surface, or off-body Y-coordinates.
YE	The value of semi-minor axis used in ellipse generation option.

OUTPUT DATA SYMBOLS

Finite Difference Boundary Layer Subprogram

Output of this routine consists of CASE DATA and STATION DATA inputs as well as the computed STATION DATA. Body geometry data, flags and counters, and reference quantities are printed out under the heading of CASE DATA. Values of parameters at the outer edge of the boundary layer as well as the boundary condition inputs are printed out under the heading of STATION DATA. These are followed by iteration results, velocity profiles for each x-station (if FLG32 = 0), and a summary of the computed boundary-layer parameters as functions of streamwise or x-distance.

Error messages generated by the program are printed out at the end of the STATION DATA printout if they are generated by input errors. Other error messages are issued at different locations in the profile printout if errors are detected during the computations.

<u>SYMBOL</u>	<u>DESCRIPTION</u>
ALPH1	Local body slope dy/dx .
ALPH2	Not used in this program.
BETA	$\beta = (2\xi/u_e)(du_e/d\xi)$
C	CHORD
CDBASE	Base drag coefficient.
CF	$c_f = \tau_w / (1/2 u_e^2)$, value of local skin friction coefficient.
CFA	Total integrated skin friction to each point.
C_p	Pressure coefficient
DELS	Boundary layer displacement thickness.
DELWV	Delta V(1,2) used in iteration for V(1,2).
EPS	ϵ^+ , eddy viscosity parameter for outer region.
EPS1	ϵ_1 , eddy viscosity parameter for inner region.
ETA	η , non-dimensionalized boundary layer thickness to each point in the boundary layer.

<u>SYMBOL</u>	<u>DESCRIPTION</u>
ETA _E	η_{∞} value of η which corresponds to δ .
ETA _{INF}	Non-dimensional boundary layer thickness used as maximum value in forming numerical solution grid.
F,FP,FPP	f, f', f'' , respectively.
FPPW	f'' at the wall.
FPW	$f' = U/U_e$ at the wall.
FW	f_w , this is the transformed stream function at the wall.
	$f_w = - \frac{1}{(2\xi)^{1/2}} \int_0^{\xi} \frac{v_w}{\mu_e u_e} d\xi$
GW	Not used in this method.
GPW	Not used in this method.
H	Boundary layer form factor, $H = \delta^*/\theta$
HE	Enthalpy
H1	Initial step size, same as DETAL in input.
IMAX	Number of points taken through the boundary layer.
K	Initial step size of the variable grid system.
KK	Variable grid parameter chosen internally.
ME	Local Mach number.
MUE	Local dynamic viscosity, μ_e , at edge of boundary layer.
MREF	Free stream Mach number.
MUREF	Free stream dynamic viscosity, μ_{∞} .
PE	Pressure at edge of boundary layer, P_e .
PRO	Laminar Prandtl number.
QW	Not used in this program.
REY	Reynolds number based on reference conditions (see input)

<u>SYMBOL</u>	<u>DESCRIPTION</u>
RHOREF	Freestream reference density.
R_0/C	R_0/L axisymmetric radius.
RR	Not used by this program.
RTHETA	Momentum thickness Reynolds number, R_θ .
R_x	Reynolds number based on local conditions. $R_x = \frac{u_e x}{\nu}$
S	Surface distance.
S/C	Nondimensionalized surface distance.
SHORTP	Flag which tells program to print velocity profiles. Same as FLG32 in input.
SQUIG	Transformed x-coordinate, ξ $\xi = \int_0^x \rho_e \mu_e u_e \left(\frac{r_0}{L}\right)^{2k} dx$
ST	Not used in this program.
SWEEP	Not used in this program.
TE	Temperature through boundary layer. Not needed for this program.
THETA	Momentum thickness, θ .
TREF	Reference temperature, T_∞ .
TRFLAG	Flag which determines transition (input).
TRINT	Flag which determines instantaneous transition or use of transitional region option (input).
TW	Temperature at the wall. Not used in this program.
TVC	Transverse curvature flag (input).
UE	Velocity at edge of boundary layer.
UPLUS	Non-dimensionlized velocity in the boundary layer.

<u>SYMBOL</u>	<u>DESCRIPTION</u>
X	X-coordinate
X/C	Non-dimensionalized x-coordinate
XI	Transformed x-coordinate - same as SQUIG
Y	Y-coordinate
Y/C	Non-dimensionalized y-coordinate
YPLUS	Non-dimensionalized y-coordinate in boundary layer.
VREF	Reference velocity (input)

Iteration Subprogram

XNEW and YNEW These are the coordinates of the equivalent viscous body. The original coordinates modified by the addition of the boundary layer displacement thickness δ^* .

DESCRIPTION OF STORAGE UNITS

The following is a description of all disk storage units used in ADAM:

<u>TAPE</u>	<u>DESCRIPTION</u>
TAPE1	This unit used in subroutine SOLVIT as a scratch unit and also used to transfer the "viscous" coordinates from subroutine iterat to subroutine smooth or subroutine BASIC1.
TAPE2	This unit used in subroutine SOLVIT as a scratch unit and also used to transfer the boundary layer displacement thickness's from subroutine OTPT to subroutine ITERAT.
TAPE3	This unit used to store source densities in subroutine SOLVIT and used to transfer body geometry and pressures from subroutine AXIS to subroutine INPT.
TAPE4	$\sin \alpha$, $\cos \alpha$, TCNST, TG(I), $\cos R^2$, $2 (\sin \alpha) (\cos \alpha) $, N_o , T_o , V_N , T_T , A(J), B(J), etc. Used exclusively in Neumann subprogram to store and transfer data.
TAPE5	This tape used for card input.
TAPE6	This tape used for printed output.
TAPE8	This tape used to store extra cross flow matrices, EC , Ecy, ECz, in subroutine MATRIX.
TAPE9	This tape used to store axisymmetric flow matrices AS, AY, AZ, in subroutine MATRIX.
TAPE10	This tape used to store cross flow matrices CX, CY, CZ in subroutine matrix and also used to transfer smoothed

<u>TAPE</u>	<u>DESCRIPTION</u>
TAPE10 (Continued)	coordinate data from subroutine smooth to subroutine BASIC1.
TAPE11	This tape used as a scratch unit in subroutine SOLVIT.
TAPE12	This tape used to store transformed parameters X1, Y1, X2, Y2, and ΔS_1 .
TAPE13	This tape used to store untransformed coordinates (TX1, TY1) for use in SUBCASE option.
TAPE15	This tape used to store transformed coordinates, (X1, Y1) for use in subroutine ITERAT.

APPENDIX C

PROGRAM LISTINGS

This part of the report contains the source card listings for the axisymmetric design and analysis method (ADAM) computer program. This program may be run either on a CDC or an IBM computer. The listing as presented here is for the CDC version of the program. This program has been run on the CDC 6600 computer. The program is written in FORTRAN for the CDC run compiler and has been run under the scope 3.1 and 3.4 operating systems. In this listing all cards that are peculiar to the CDC version of FORTRAN are identified by a C in card column 80. All cards that are peculiar to the IBM FORTRAN IV compiler are identified by an I in card column 80 and a C in card column 1. In other words, the code for both CDC and IBM machines is in the deck but the IBM cards are made inactive by converting them to comment statements (C in card column 1). Since all of the machine dependent cards are identified by an I or C in card column 80 it is a simple matter to convert the deck from one version to the other with a small conversion program. When converting from CDC to IBM code this conversion program reads and copies each card to a storage unit. If a card has a C in card column 80, then a C is written into card column 1 to make the CDC peculiar card inactive. If a card has an I in card column 80, then the C is removed from card column 1 and the card image written to the storage unit as an active FORTRAN statement. The conversion from IBM back to CDC is made in a similar manner. The conversion program to convert the deck from CDC to IBM FORTRAN is listed below (for use on an IBM machine):

```

      DIMENSION DATA(22)
      DATA CB,CC,CI/IH, IHC,IHI/
      REWIND 19
      DO 100 I=1,20000
        READ (5,20,END=300) DATA
    20      FORMAT (1A1,19A4,1A2,1A1)
        IF (DATA(22) .EQ. CI) DATA(1) = CB
        IF (DATA(22) .EQ. CC) DATA(1) = CC
        WRITE (19,20) DATA
    100 CONTINUE
    300 STOP
      END
```

This program places the new deck with IBM cards made active, and CDC cards inactive, on to unit 19. The references to unit 19 above can be changed to unit 7 to punch the deck out.

```

"The aeronautical and space activities of the United States shall be conducted so as to contribute . . . to the expansion of human knowledge of phenomena in the atmosphere and space. The Administration shall provide for the widest practicable and appropriate dissemination of information concerning its activities and the results thereof."

—NATIONAL AERONAUTICS AND SPACE ACT OF 1958

NASA SCIENTIFIC AND TECHNICAL PUBLICATIONS

TECHNICAL REPORTS: Scientific and technical information considered important, complete, and a lasting contribution to existing knowledge.

TECHNICAL NOTES: Information less broad in scope but nevertheless of importance as a contribution to existing knowledge.

TECHNICAL MEMORANDUMS: Information receiving limited distribution because of preliminary data, security classification, or other reasons. Also includes conference proceedings with either limited or unlimited distribution.

CONTRACTOR REPORTS: Scientific and technical information generated under a NASA contract or grant and considered an important contribution to existing knowledge.

TECHNICAL TRANSLATIONS: Information published in a foreign language considered to merit NASA distribution in English.

SPECIAL PUBLICATIONS: Information derived from or of value to NASA activities. Publications include final reports of major projects, monographs, data compilations, handbooks, sourcebooks, and special bibliographies.

TECHNOLOGY UTILIZATION PUBLICATIONS: Information on technology used by NASA that may be of particular interest in commercial and other non-aerospace applications. Publications include Tech Briefs, Technology Utilization Reports and Technology Surveys.

Details on the availability of these publications may be obtained from:
