TABLE OF CONTENTS

1.0 SUMMARY

A series of tests were conducted to define the characteristics of an ASF 11 Ride Truck Assembly including joint slop, friction and stiffness. Loading to the truck assembly included vertical load to simulate the car/coal loading combined with lateral or moment loading that resulted in desired truck deflections for the various phases of testing. All seven test conditions were successfully completed with load and deflection data being collected. No attempt is made in this report to reduce the applicable data other than to provide computer plots. The Dynamics and Loads Analysis Section will utilize the test data for computer model correlation.

2.0 TEST SPECIMEN

The test specimen was an ASF 11 Ride Truck Assembly supplied to Martin Marietta Corporation by the Louisville and Nashville Railroad. The ride truck assembly was equipped with Brenco 6X11 roller bearing assemblies.

The ride truck assembly appeared to be fairly new as very little wear was present on the bolster to body center plate contact area or on the wheel to rail contact area. Photo 1 shows the ride truck assembly as received. Photo 2 is a close up of the bolster cup area showing rust and scale present in the as received condition. For testing the area was buffed and cleaned to the condition shown in photo 3. Also shown in photo 3 are wear marks in the bolster cup rim from body center plate rivet contact.

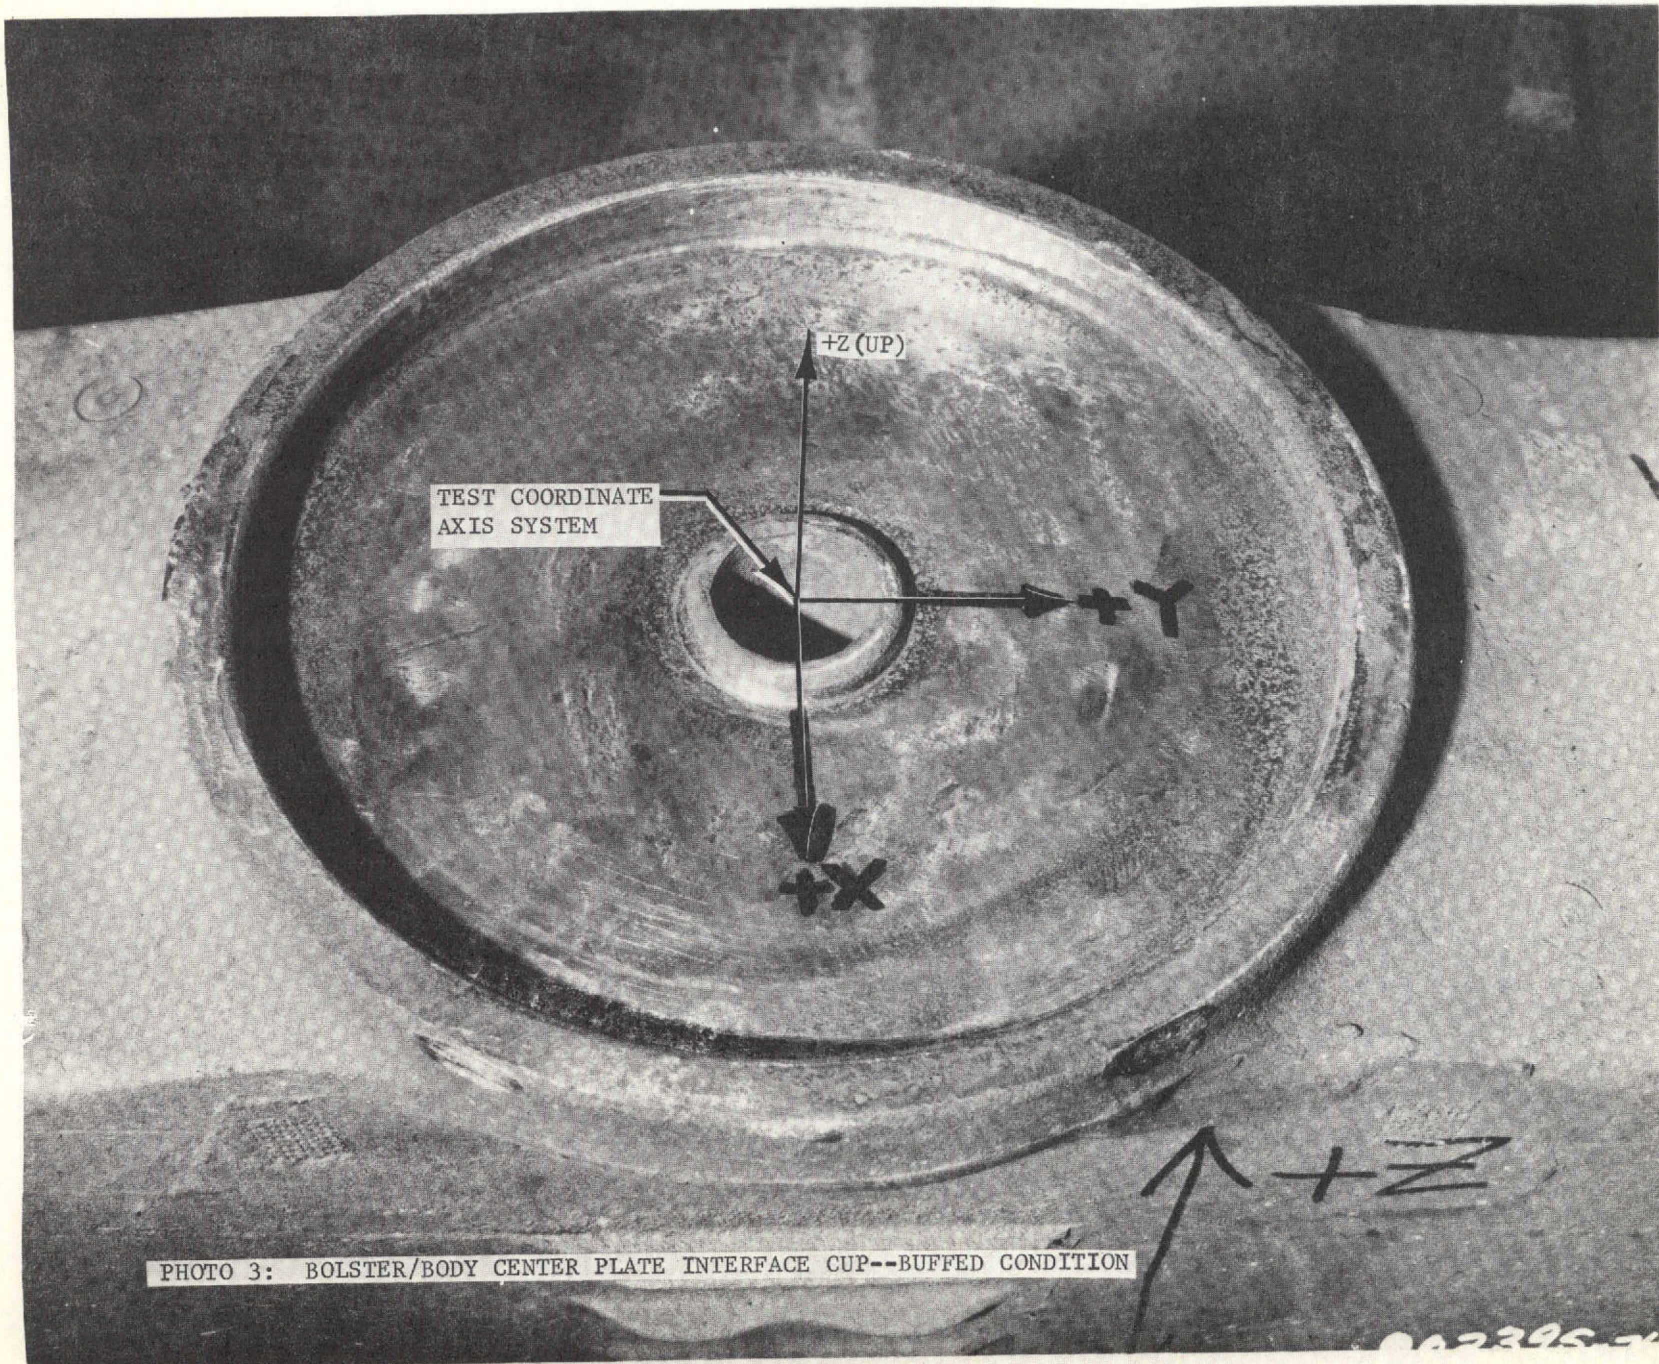

PHOTO 3: BOLSTER/BODY CENTER PLATE INTERFACE CUP--BUFFED CONDITION

3.0 TEST SETUP AND LOADS

Two major testing fixtures were required to complete the testing of the ride truck assembly. The fabrication of these test fixtures and setup of the test phases is documented on MMC drawing LAB1007045 that is included as Appendix B of this report. Phases 1 through 5 were conducted with the ride truck assembly in the normal operating position. Phases 6 and 7 were conducted with the ride truck assembly in an inverted position.

Since it was desirable that the lateral and moment loading be cyclic with a controllable amplitude and frequency, a servo-controlled loading system was incorporated. The system consisted of a 5000 psi hydraulic supply pump, two 50,000 pound hydraulic actuators, two 20,000 pound load cells, two 15 gallon/minute Moog servo valves, two Bristol recorders, a function generator and control panel.

A sine wave form loading was controlled by setting the desired load (amplitude) and frequency with the function generator and control panel (photo 4). The load cells were used for feedback in the load lines so that the Moog servo valves (photo 5) could control the desired loading. Two Bristol strip recorders were used for displaying and recording the cyclic loading.

The vertical load was applied in three increments for all phases of testing. These increments were 20,000 pounds (light car simulation), 50,000 pounds, and 100,000 pounds (full car simulation). The cyclic loading had a maximum amplitude of $\pm$10,000 pounds with frequencies of 0.25 cycles/second and 0.50 cycles/second. The sequential

PHOTO 4: SERVO SYSTEM CONTROL STATION

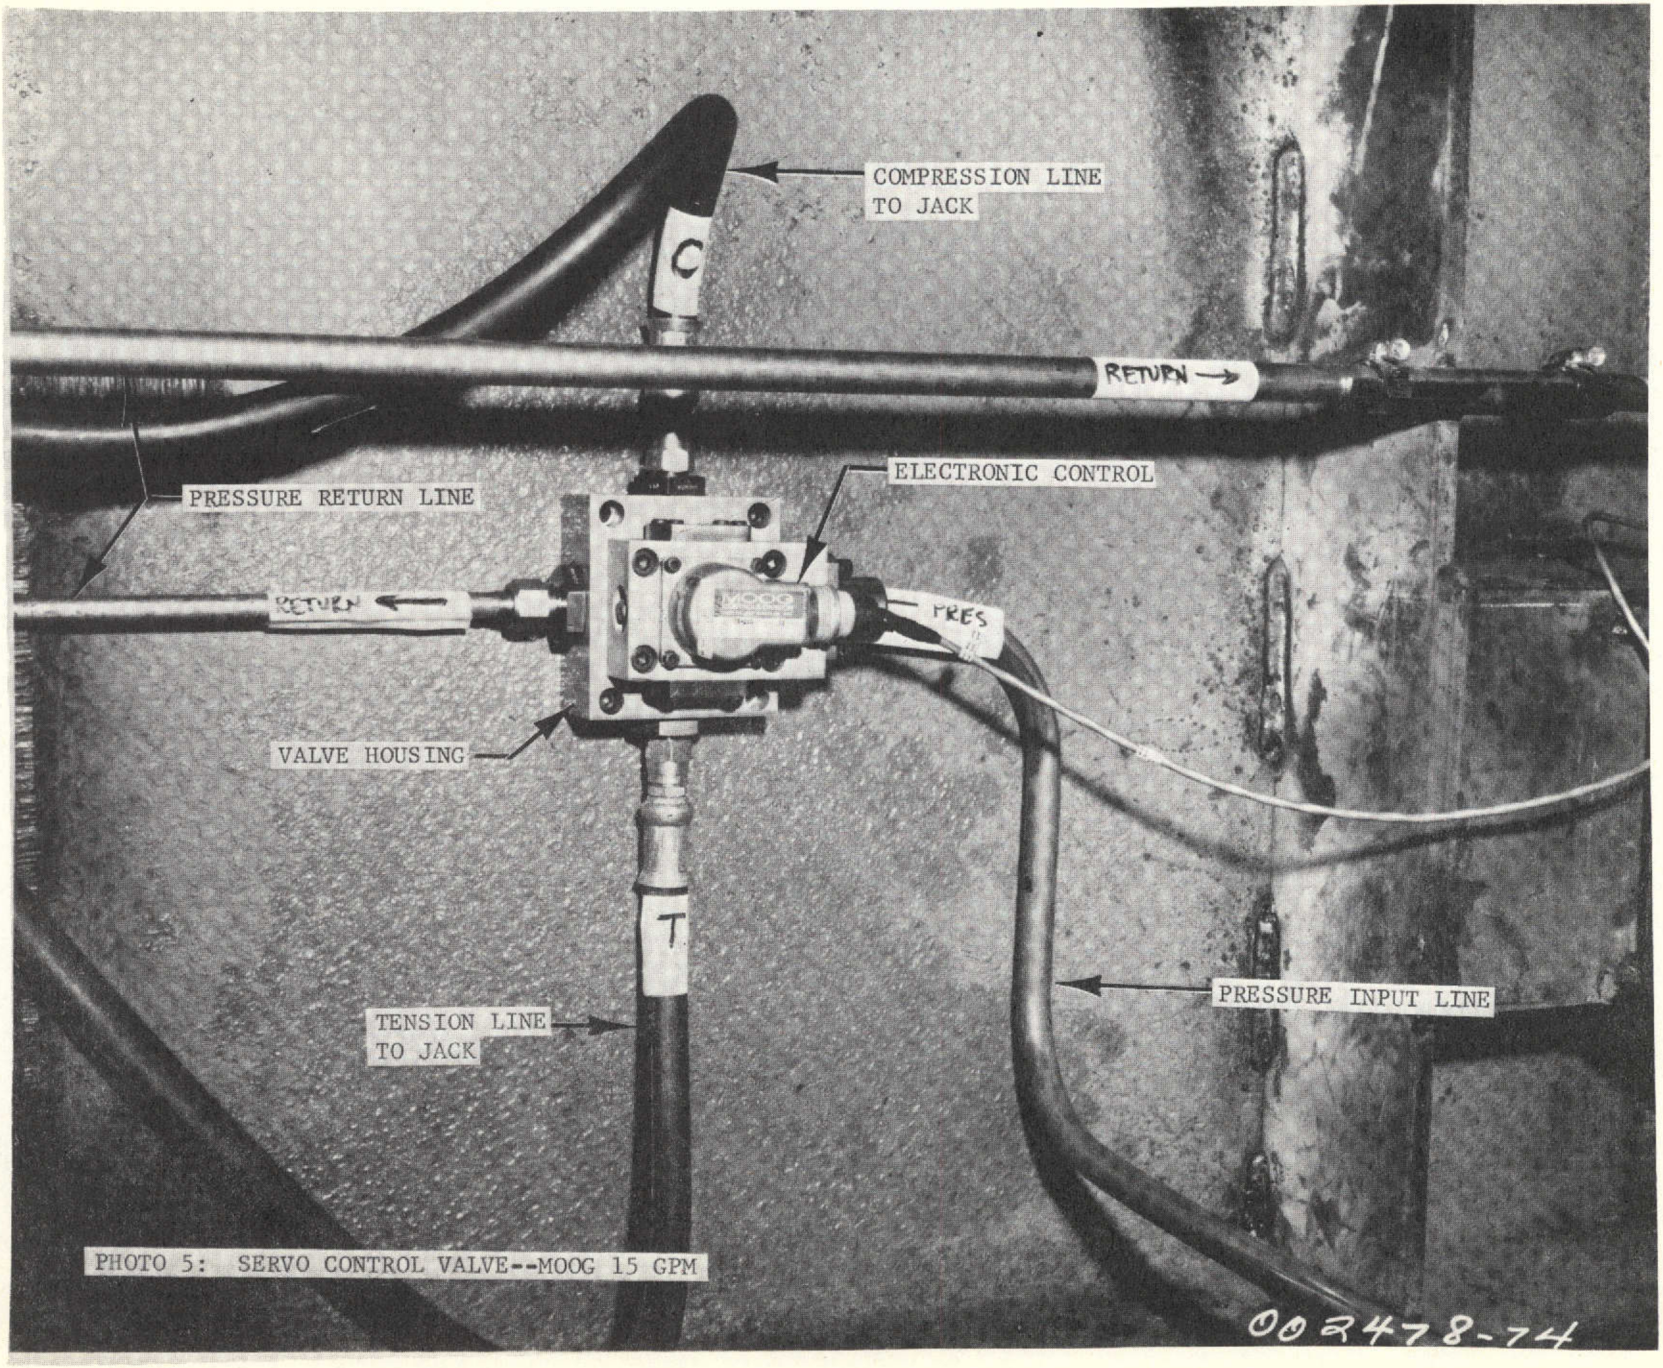

PHOTO 5: SERVO CONTROL VALVE--MOOG 15 GPM

operations section of the Test Procedure, Appendix A of this report, documents the specific loading combinations during the different phases of testing.

For Phases 1 through 5, the hopper car loading was simulated using one vertical load line loading the bolster through a body center plate welded to a load fitting. Photo 6 shows the body center plate as it was welded into the load fitting. The rust and scale were buffed from the plate to provide a clean interface surface. Lateral and moment loading was introduced into the bolster utilizing a cross beam welded to the body center plate load lug as well as two fittings welded to the opposite ends of the bolster. Photo 7 shows a close-up of the bolster end fittings while photo 8 shows the lateral load fittings as well as the ride truck assembly in place on the test fixture used for Phases 1 through 5. Photo 9 shows the lube pads that were used in the testing of Phases 1 through 5. Photo 10 shows the bolster load lug fitting under the bolster with the vertical preload load line universal and load cell in place. In photo 11, the wheel chocks used to prevent rolling of the wheels in Phases 1 through 5 are shown welded in place. These chocks were used on all four wheels for the testing.

Phase 1 testing was accomplished using only the bolster vertical preload loading. No lateral or moment loading was imposed on the ride truck assembly. This test was conducted to measure the bolster suspension spring stiffness and bolster damper characteristics. Photos 8 and 11 present the setup for Phase 1.

Phase 2 testing combines both bolster vertical loading and cyclic lateral (±Y axis) loading. Photo 12 presents the servo control

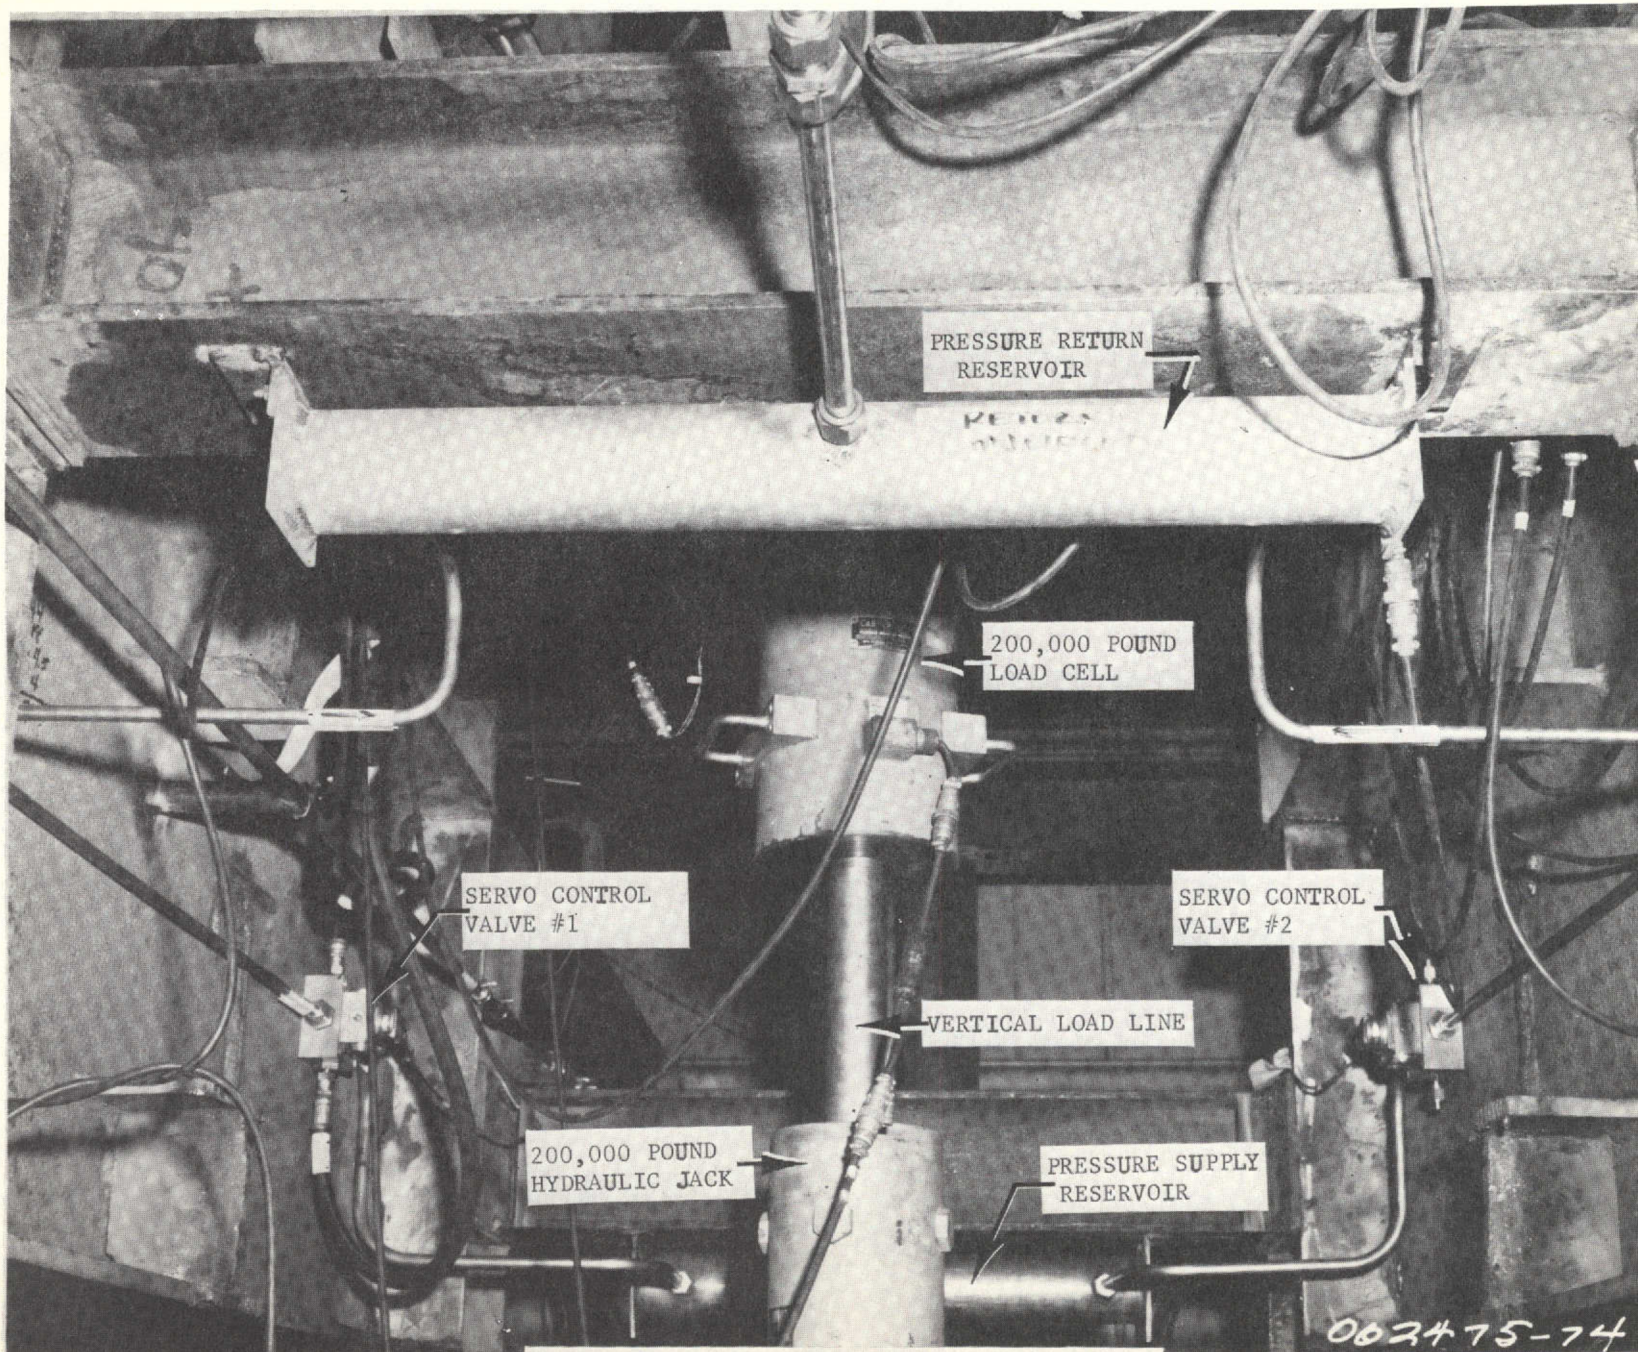

PHOTO 12: SERVO CONTROL SYSTEM INSTALLATION

system and vertical load line used in Phases 2 through 5. Phase 2 conducted to measure the lateral bolster to side frame slop and lateral side frame to axle slop and friction. Photo 13 presents the setup.

Phase 3 combines bolster vertical loading with cyclic longitudinal (±X axis) loading. This test was conducted to measure the longitudinal bolster to sideframe slop and sideframe to axle friction. Wood blocks were required to prevent rotation of the bolster loading lug. Photo 14 presents the setup.

Phase 4 combines bolster vertical loading with cyclic moment (±My) loading. Wood blocks were required to prevent rotation of the bolster loading lug. This test was conducted to measure the rotational characteristics of the suspension/damper. Photo 15 presents the setup.

Phase 5 combines bolster vertical loading with cyclic moment (±Mx) loading. The purpose of this test was to measure the suspension spring/damper characteristics. Photo 16 presents the setup.

For Phases 6 and 7, the ride truck assembly is inverted and supported on the bolster/body center plate interface by a column. The vertical loading is introduced into the ride truck assembly using two hydraulic load lines with one at the center of each wheel/axle assembly. The bolster is fixed from vertical motion by the support column so as vertical loading is applied, the sideframes and wheel/axle assemblies move downward to compress the suspension springs. Photo 17 shows the ride truck assembly in the inverted position on the support column. Also shown is the servo loading system used only for Phase 6 testing.

Phase 6 testing combines bolster vertical loading with racking cyclic loading. The purpose of this test is to measure the

lozenge mode characteristics. The line of action of the racking loading is through the Z-axis so that no rotation of the ride truck results. The interface between the body center plate and bolster is dry, that is, no lube pads were used during Phase 6. Photo 18 presents the setup.

Phase 7 testing was conducted to measure the breakaway torque at the interface between the body center plate and bolster. Both the lube and non-lube condition were tested. Bolster vertical loading was introduced using the two vertical load lines and the tension load in the load lines perpendicular to the bolster lateral axis was increased until bolster rotation was observed. Photo 19 presents the setup.

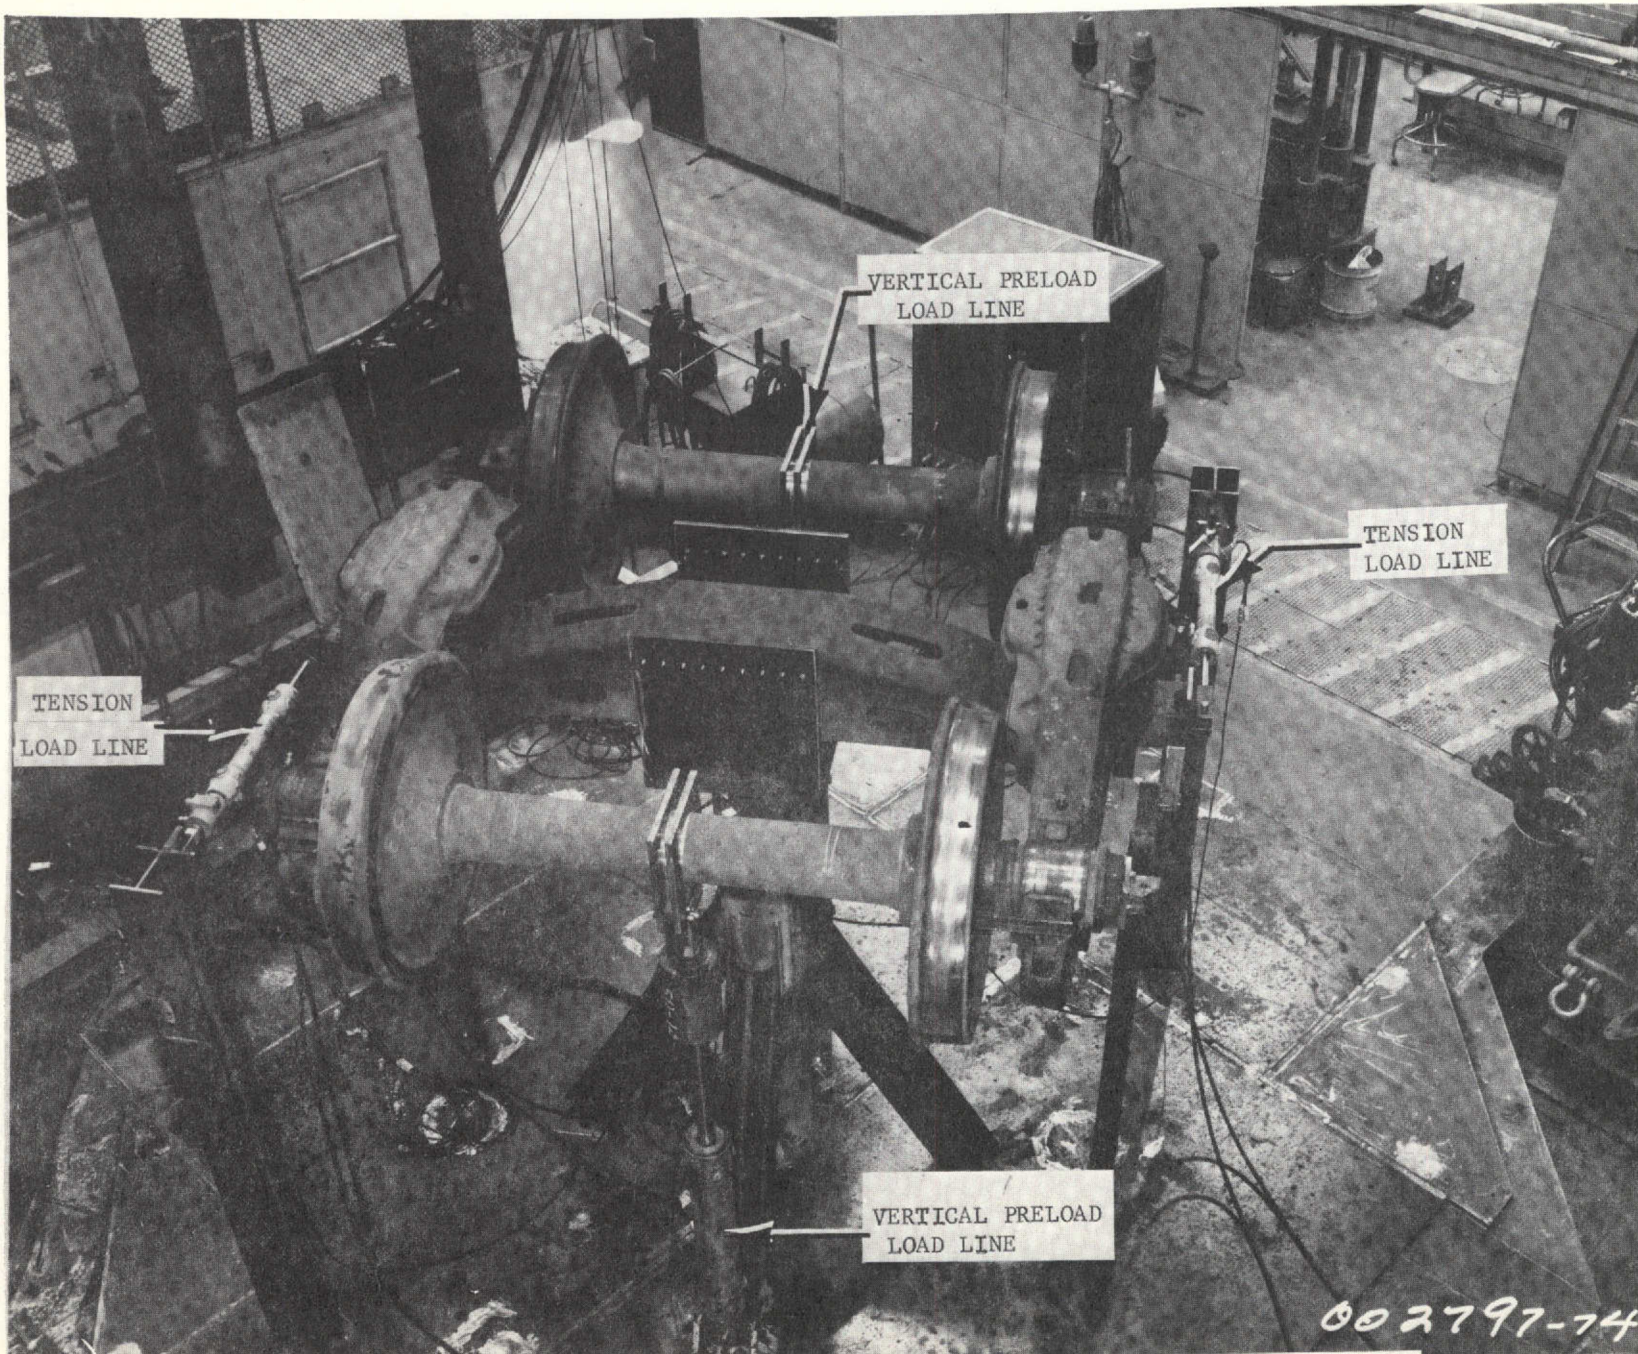

PHOTO 19: PHASE 7 TEST SETUP - BOLSTER TORQUE/FRICTION BREAKAWAY

4.0 INSTRUMENTATION

Instrumentation utilized in this test included load cells for monitoring applied loads; deflection transducers for monitoring relative deflections of the ride truck components; and recording equipement.

Load cells were used in each hydraulic load line to monitor all applied loads. These load cells are calibrated to a known applied load with a resulting voltage output. This voltage signal was recorded on magnetic tape and Leets and Northrup polar plots and also was used as feedback for the servo system. Photos 10 and 12 show the load cell used in Phase 1 through 5 testing to monitor the vertical preloading. Photo 13 shows the location of the load cell used in the lateral and moment load lines. Photo 17 shows the load cells used for Phases 6 and 7 vertical loading load lines.

Two types of deflection transducers were used for monitoring relative deflections of the ride truck. The output from these transducers is a continuous DC voltage that had been calibrated to a known deflection. Linear variable deflection transducers (LVDT) and Structure's Lab deflection transducers (SLDT) were utilized. MMC drawing LAB1007045, sheets 14 and 15, (Appendix B of this report) show the nominal location of the transducers. The accuracy of the LVDT is ±0.010 inch while that of the SLDT is ±0.030 inch. A tension load on the transducer represents a positive (+) deflection, while a compression load represents a negative (-) deflection. Photos 10, 14, 20 and 21 show typical deflection transducer installation. Tables 2 and 3 of Test Procedure MCR-74-436, were completed and give actual deflection transducer location for all phases

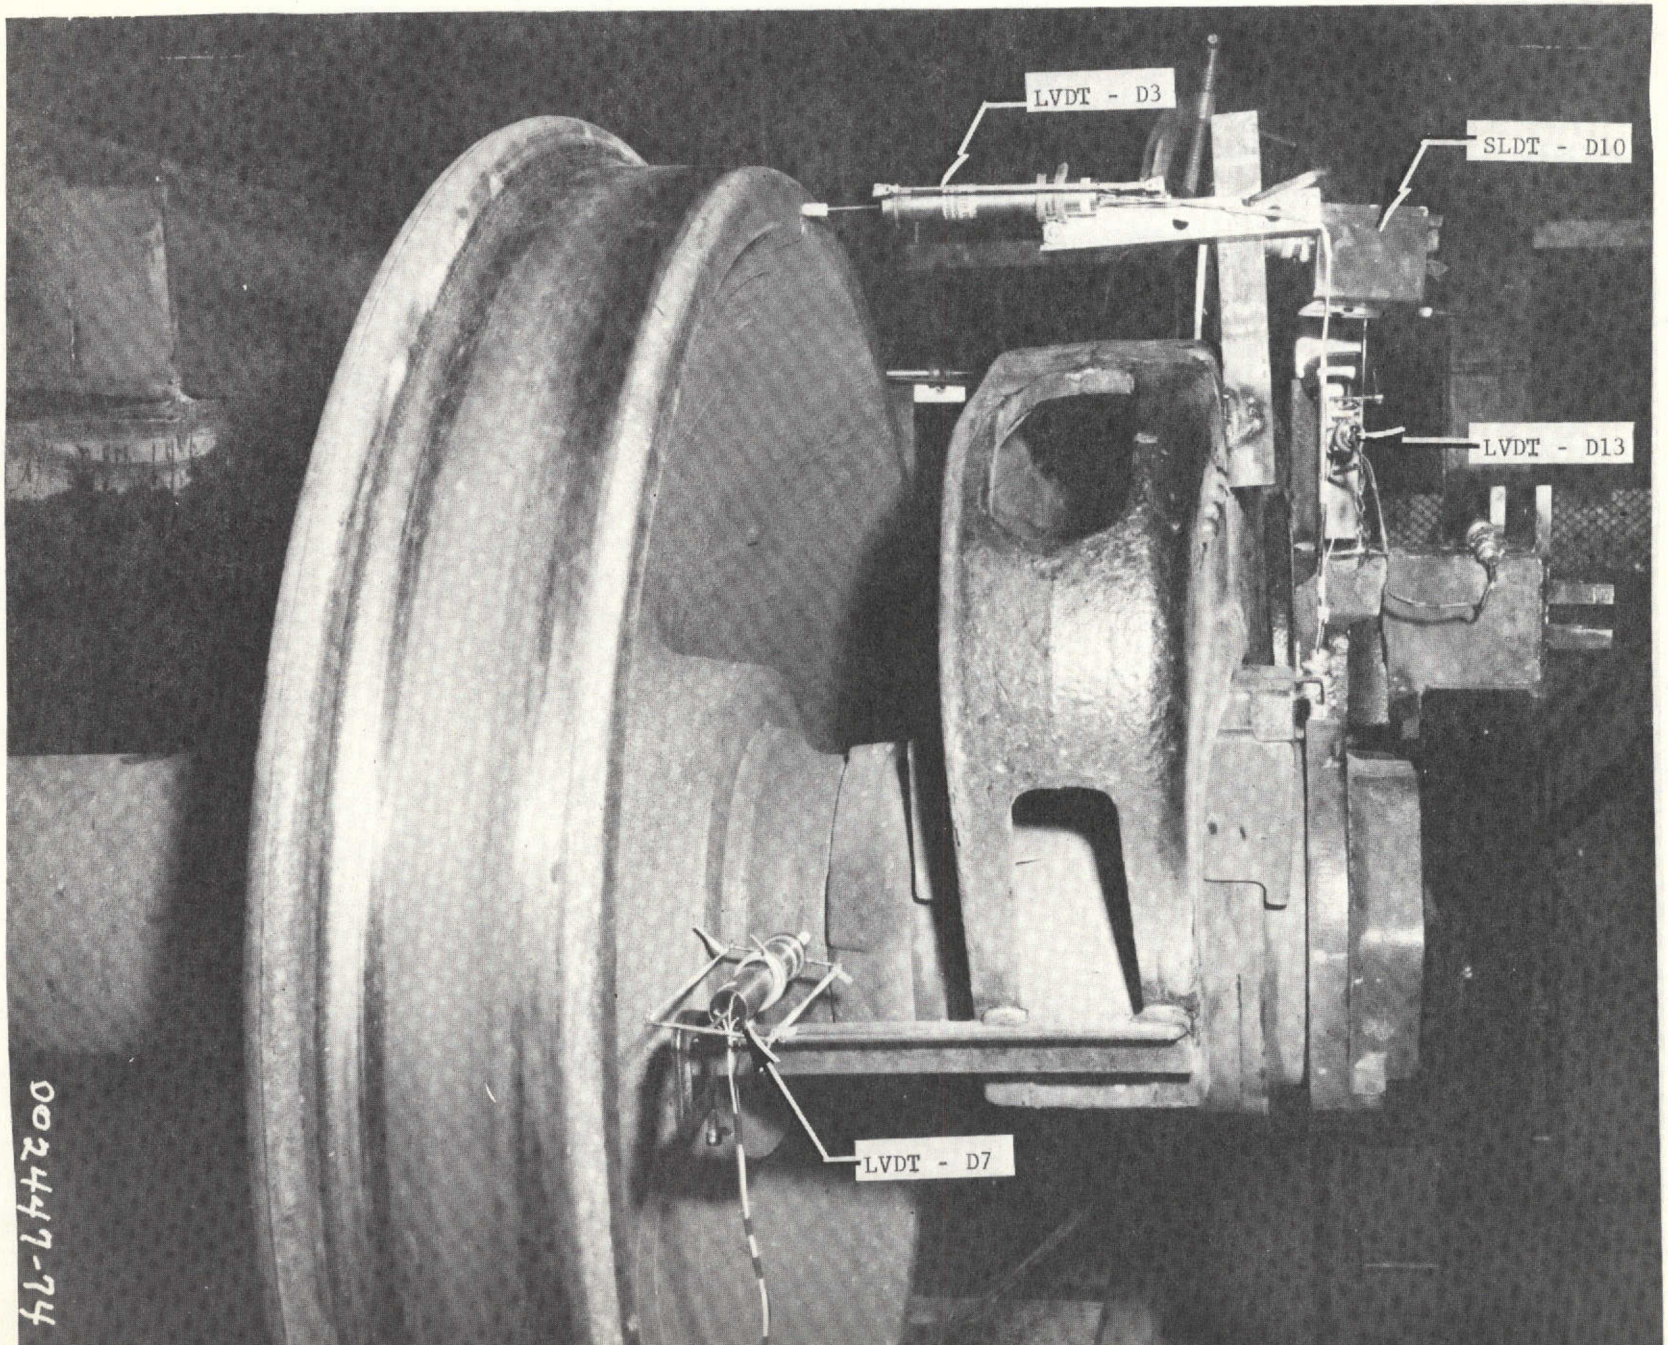

PHOTO 20: TYPICAL LINEAR VARIABLE DEFLECTION TRANSDUCER (LVDT) INSTALLATION

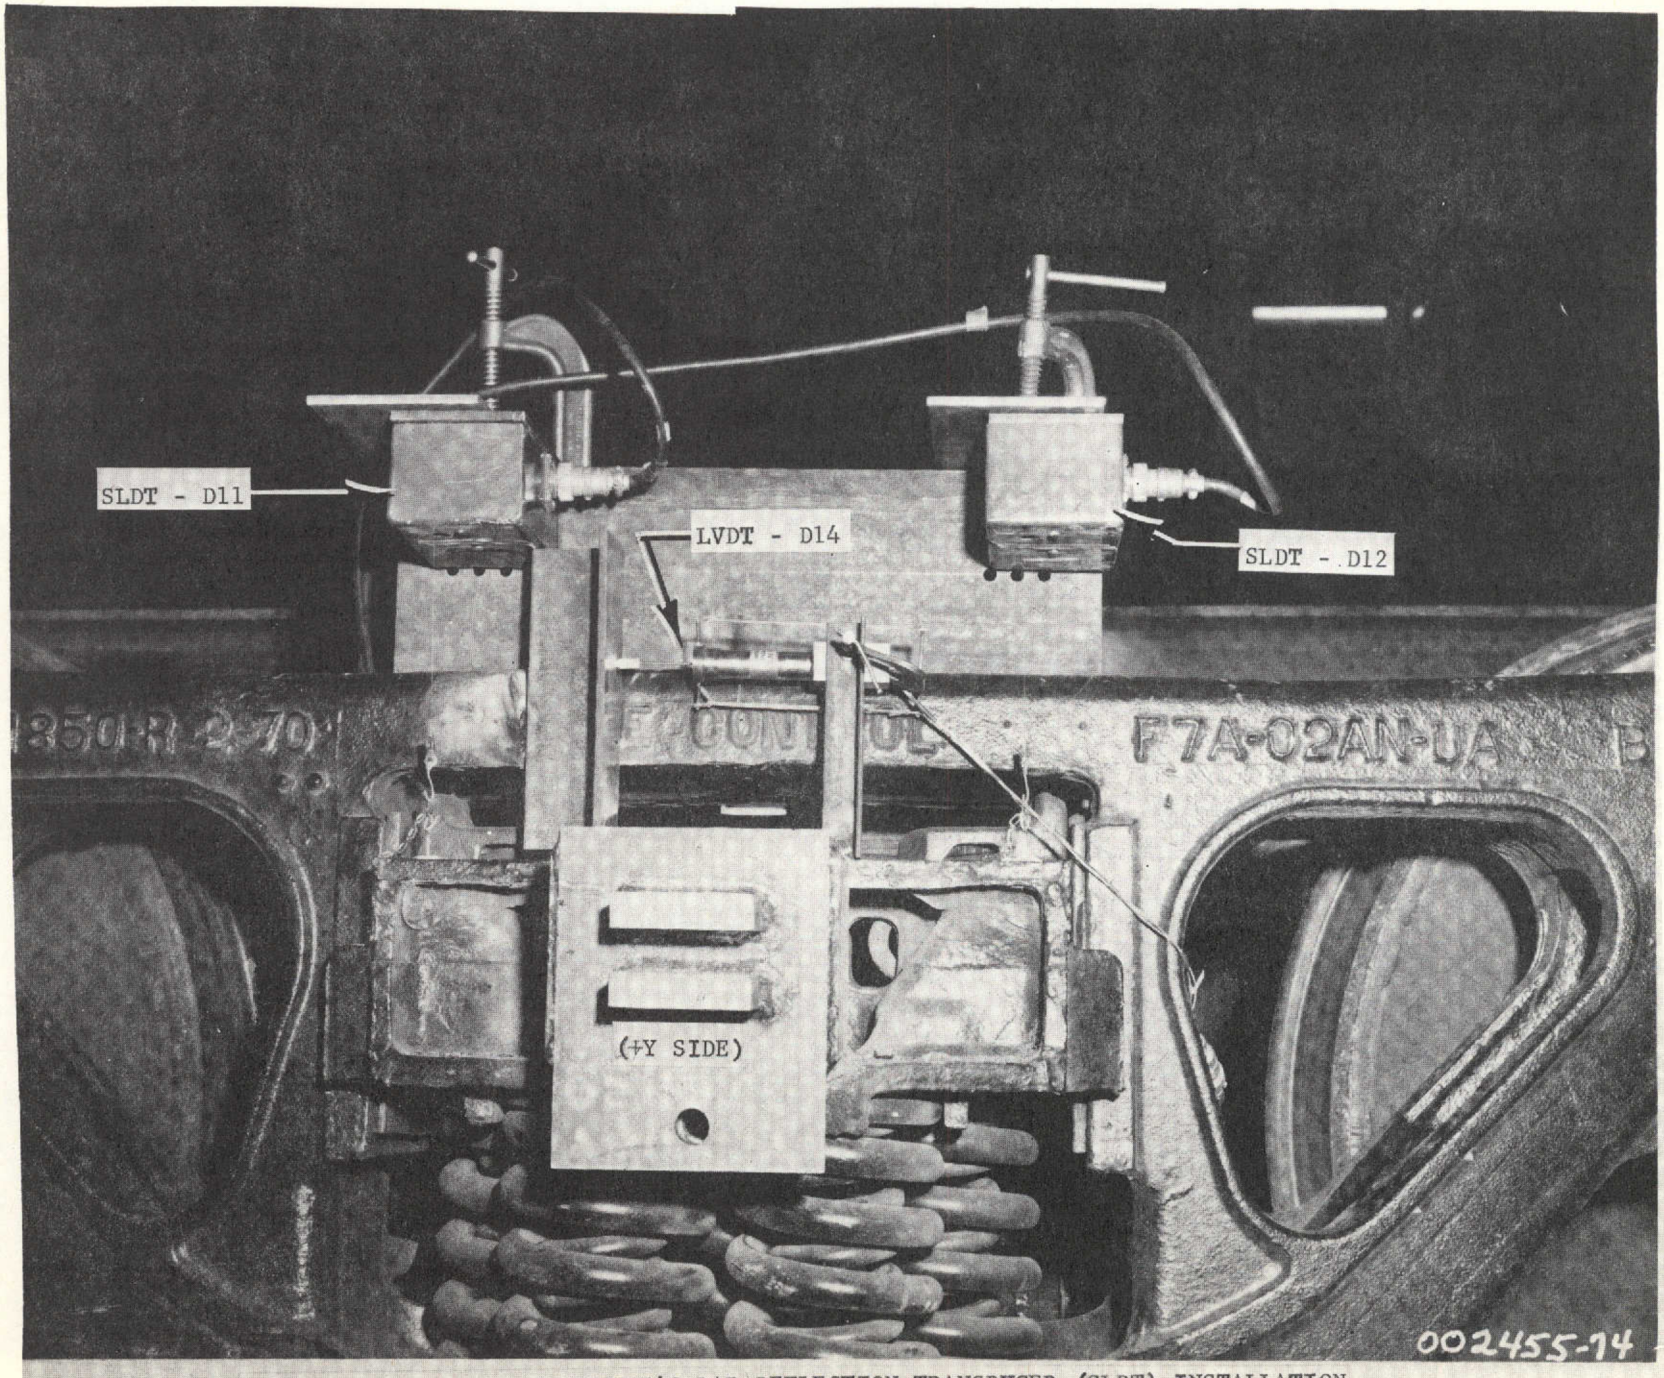

PHOTO 21: TYPICAL STRUCTURE'S LAB DEFLECTION TRANSDUCER (SLDT) INSTALLATION

of testing. These tables are included in the Test Log portion of Appendix A.

Recording equipment used in this test included two Bristol strip recorders, four Leeds and Northrup polar plotters, and a low level analog to digital recording system. The Bristol strip recorders (Photo 4) were used in the servo control system to record the cyclic load line output. The Leeds and Northrup (L&N) polar platters (Photo 18) were used to record the load cell outputs from all other load lines. The low level analog to digital recording system was used to record all loading and deflection data on magnetic tape. Each channel of data was recorded 100 times each second. A computer printout of the data was then made from the magnetic tape.

5.0 TEST RESULTS

The results of the ride truck assembly testing is presented in both plots and tabular data. For Phases 1 through 6, there are 234 plots included. Graphs of load plotted against deflection for particular deflection transducers are presented rather than the raw computer tab run data. The data collected for Phase 7 testing was the breakaway torque of the bolster/body center plate interface cup for both lube and non-lube conditions.

The vertical axis of all graphs presents the applied load in pounds while the horizontal axis presents the resulting deflection for a particular deflection gage. The time the data collection was started is in the lower left corner of the plot. The deflection gage identification number is listed on the bottom of the page; for example, D9X10. A positive deflection represents tension on the deflection gage while a negative deflection results from compression. Sheets 14 and 15 of MMC drawing LAB1007045, Appendix B, gives the gage locations. The legend in the upper left corner indicates which load cell is being plotted. Above the legend is the title of the test phase followed by the date the test was conducted.

Figures 1 through 4 present the plots resulting from Phase 1 testing. The vertical loading (LC01) was increased and data collected in four increments; 20,000 pounds, 50,000 pounds, 75,000 pounds and 100,000 pounds. Data was continuously recorded as the vertical loading was freely allowed to return to zero. The offset from the initial loading represents friction present suspension system. Plots are presented for deflection gages D9, D10, D11 and D12. No significant deflections were recorded on any other gages.

For Phases 2 through 6, the deflection gages were system calibrated and zeroed before each phase of testing was conducted. No attempt was made to return the ride truck assembly to the initial nominal or zeroed position between loading increments. Therefore, shifts in the plots for various gages may be noted throughout the plots presented and do not effect the local hysterisis or friction characteristics.

Figures 5 through 58 present the plots from Phase 2 testing. Those gages with significant deflections are D1 through D6, D15, D16 and D18. The cyclic lateral load applied in the $\pm$Y axis to the bolster was $\pm$10,000 pounds. The plots presented are figures 5 through 13 for 20,000 pound vertical loading with 0.50 Hz lateral cyclic loading; figures 14 through 22 for 20,000 pound vertical loading with 0.25 Hz lateral cyclic loading, figures 23 through 31 for 50,000 pound vertical loading with 0.50 Hz lateral cyclic loading, figures 32 through 40 for 50,000 pound vertical loading with 0.25 Hz lateral cyclic loading, figures 41 through 49 for 100,000 pound vertical loading with 0.50 Hz lateral cyclic loading, and figures 50 through 58 for 100,000 pound vertical loading with 0.25 Hz lateral cyclic loading.

For Phase 3 testing, only gages D9 through D12 registered significant deflections and these deflections resulted from the vertical loading rather than the cyclic lateral loading. Since the data from Phase 1 defined the suspension system characteristics using deflections from gages D9 through D12, the decision was made by the technical director that no plots were required for Phase 3.

Figures 59 through 94 present the plots from Phase 4 testing. Significant deflections were recorded on gages D9 through D12, D13 and D14 and plots for those gages are included. A moment ($\pm M_y$) cyclic loading was applied to the ride truck assembly. Each plot includes the load/deflection data for the two load cells producing the cyclic moment. The plots presented are figures 59 through 64 for 20,000 pound vertical loading with 0.50 Hz cyclic moment loading, figures 65 through 70 for 20,000 pound vertical loading with 0.25 Hz cyclic moment loading, figures 71 through 76 for 50,000 pound vertical loading with 0.25 Hz cyclic moment loading, figures 77 through 82 for 50,000 pound vertical loading with 0.50 Hz cyclic moment loading, figures 83 through 88 for 100,000 pound vertical loading with 0.50 Hz cyclic moment loading, and figures 89 through 94 for 100,000 pound vertical loading with 0.25 Hz cyclic moment loading.

Figures 95 through 154 present the plots from Phase 5 testing. Significant deflections were recorded on D1 through D6 and D9 through D12 and plots only for those gages are presented. A cyclic moment ($\pm M_x$) loading is applied to the ride truck assembly. The load/deflection plot for the two load cells against each applicable deflection gage is included on each plot. The plots presented are for 20,000 pound vertical loading figures 95 through 104 at 0.50 Hz cyclic moment loading and figures 105 through 114 at 0.25 Hz cyclic moment loading, for 50,000 pound vertical loading figures 115 through 124 at 0.25 Hz cyclic moment loading and figures 125 through 134 at 0.50 Hz cyclic moment loading, and for 100,000 pound vertical loading figures 135 through 144 at 0.50 Hz cyclic moment loading and figures 145 through 154 at 0.25 Hz cyclic moment loading.

Phase 6 testing required three separate runs to complete. These runs are designated 6-1, 6-2 and 6-3. Significant deflections were recorded on gages D1 through D16 and D19 through D22. For Phase 6-1, Figures 155 through 174 are for 100,000 pound vertical loading with ±10,000 pound cyclic racking loading applied at 0.50 Hz. For Phase 6-2, Figures 175 through 195 are for 20,000 pound vertical loading with ±10,000 pound cyclic racking loading applied at 0.50 Hz. Phase 6-3 presents plots from additional testing at 20,000 pound vertical loading with reduced cyclic racking loading. Figures 195 through 214 are plots for ±2,000 pound cyclic racking loading at 0.50 Hz and Figures 215 through 234 are plots for ±5,000 pound cyclic racking loading at 0.50 Hz.

It should be noted that no lube pads were used for Phase 6 testing and that there was no rotation or translation between the bolster and the body center plate during the testing.

Phase 7 testing was conducted to determine the breakaway torque between the bolster and body center plate for both the lubed and non-lubed condition. Each test was conducted with 20,000 pound, 50,000 pound and 100,000 pound vertical loading. A tension couple with a moment arm between the loads of 106.24 inches was continuously increased until the bolster rotated.

Table 1 presents the data collected for the lubed condition of the bolster/body center plate interface. Inspection of the lube pads after testing showed that the pads were not fully compressed to fill the available bearing area so that during the testing the breakaway torque measured would be between the metal and lube pad.

Table 1. Phase 7--Bolster/Body Center Plate Lubed Condition

Run No.	Total Vertical Load (lbs)	Lateral Load (lbs)		Breakaway Torque (LCØ3+LCØ4)*(53.12) (in-lb)
		LCØ3	LCØ4	
1	20,320.	154.80	144.00	15,900.
2	20,240.	126.80	140.80	14,200.
3	20,080	123.20	127.60	13,300.
4	50,040.	156.40	162.80	16,950.
5	50,160.	146.00	154.00	15,950.
6	49,880.	184.00	193.60	20,050.
7	99,600.	253.60	265.60	27,600.
8	99,760.	226.00	237.20	24,600.
9	99,840.	224.80	238.80	24,600.

Table 2 presents the data collected for the non-lubed condition. Inspection of the bearing area after testing showed definite metal scratches at the high spots between the bolster and body center plate. This indicates that point loading rather than complete surface area bearing was present.

Table 2. Phase 7--Bolster/Body Center Plate Non-lubed Condition

6.0 CONCLUSIONS

The data collected during these series of tests are sufficient to describe the joint slop, friction and stiffness of the ASF 11 ride truck assembly.

A general observation that can be made is that as the vertical loading on the ride truck assembly was increased, the resulting relative deflections between the components decreased.

TABLE OF CONTENTS

1.0 DESCRIPTION OF TEST

1.1 Test Objective - The basic objective of this test is to define the joint free play, sliding friction, system flexibility, and linear and non-linear characteristics of an ASF 11 ride truck assembly. Ride truck assembly load and deflection characteristics as well as friction loss characteristics of the body center plate to bolster interface will be determined.

1.2 Test Specimens - The test specimen is 2 ride truck assembly with 6 x 11 roller bearings. The truck assembly is GFP hardware that will be tested in six different configurations to obtain load and deflection data.

The truck assembly will be tested in the as received condition except that the brake beam and linkage assemblies will be removed.

1.3 Test Setup and Test Loads - The ride truck assembly test setup is defined on MMC drawing LAB 1007045. Two separate test fixtures are required to conduct the six phases of testing.

Test phases one through five are conducted on test fixture LAB 1007045-009. This fixture fixes the truck assembly so that the wheel and axles will not move during the loading phases. Only the side frames and bolster are allowed to deflect. The hopper car loading (vertical preload) is introduced into the bolster utilizing a load fitting incorporating a Pullman Standard body center plate and a 200,000 pound hydraulic jack. The maximum load will be only 100,000 pounds and the load will be monitored with a 200,000 pound load cell. Lateral and moment loading is provided by 50,000 pound hydraulic jacks separately or in pairs depending on the loading phase. The maximum lateral and moment load is only 10,000 pounds which is monitored by 20,000 pound load cells. Figure 1 summarizes the test phases one through five.

Test phases six and seven are conducted on test fixture LAB 1007045. For Phase six and seven testing the ride truck assembly is inverted on the test fixture and supported by a column that is topped with the body center plate. The hopper car loading is simulated utilizing two 100,000 pound hydraulic jacks with one jack attached to the center of the wheel axle assembly. BLH 50,000 pound load cells are used in line with the hydraulic jacks to measure the applied vertical forces.

1.3 (Continued)

Phase 6 (Lozenge Mode) lateral loading is produced utilizing two 50,000 pound hydraulic jacks with one jack attached at the end of the wheel/axle assembly. The jacks are positioned so that the line of action will produce racking of the ride truck assembly without any resulting rotation. BLH 20,000 pound load cells are utilized to monitor the hydraulic jack loading. Maximum lateral loading will be 10,000 pounds.

Phase 7 (Friction Test) lateral loading is produced utilizing two 10,000 pound hydraulic jacks with one jack attahced at each end of the bolster. The jacks are positioned so that bolster rotation results when sufficient torque is applied to overcome the friction torque between the body center plate and the bolster cup. But, 50,000 pound load cells are utilized to monitor the hydraulic jack loading. Figure 2 shows the loading directions for phase six and seven testing.

Since the lateral loading and moment producing loading must be cyclic in nature, a servo control system is incorporated. Moog servo control valves with a maximum capacity of 15.0 gal/min are used. The desired sine wave loading signal is generated with a function generator with the load amplitude and frequency set. The Load cells provide feedback for control of the cyclic loading. A second hydraulic pump is added to the setup and a pressure reservoir and an accumulator are also required. Figure 3 gives the hydraulic servo system schematic.

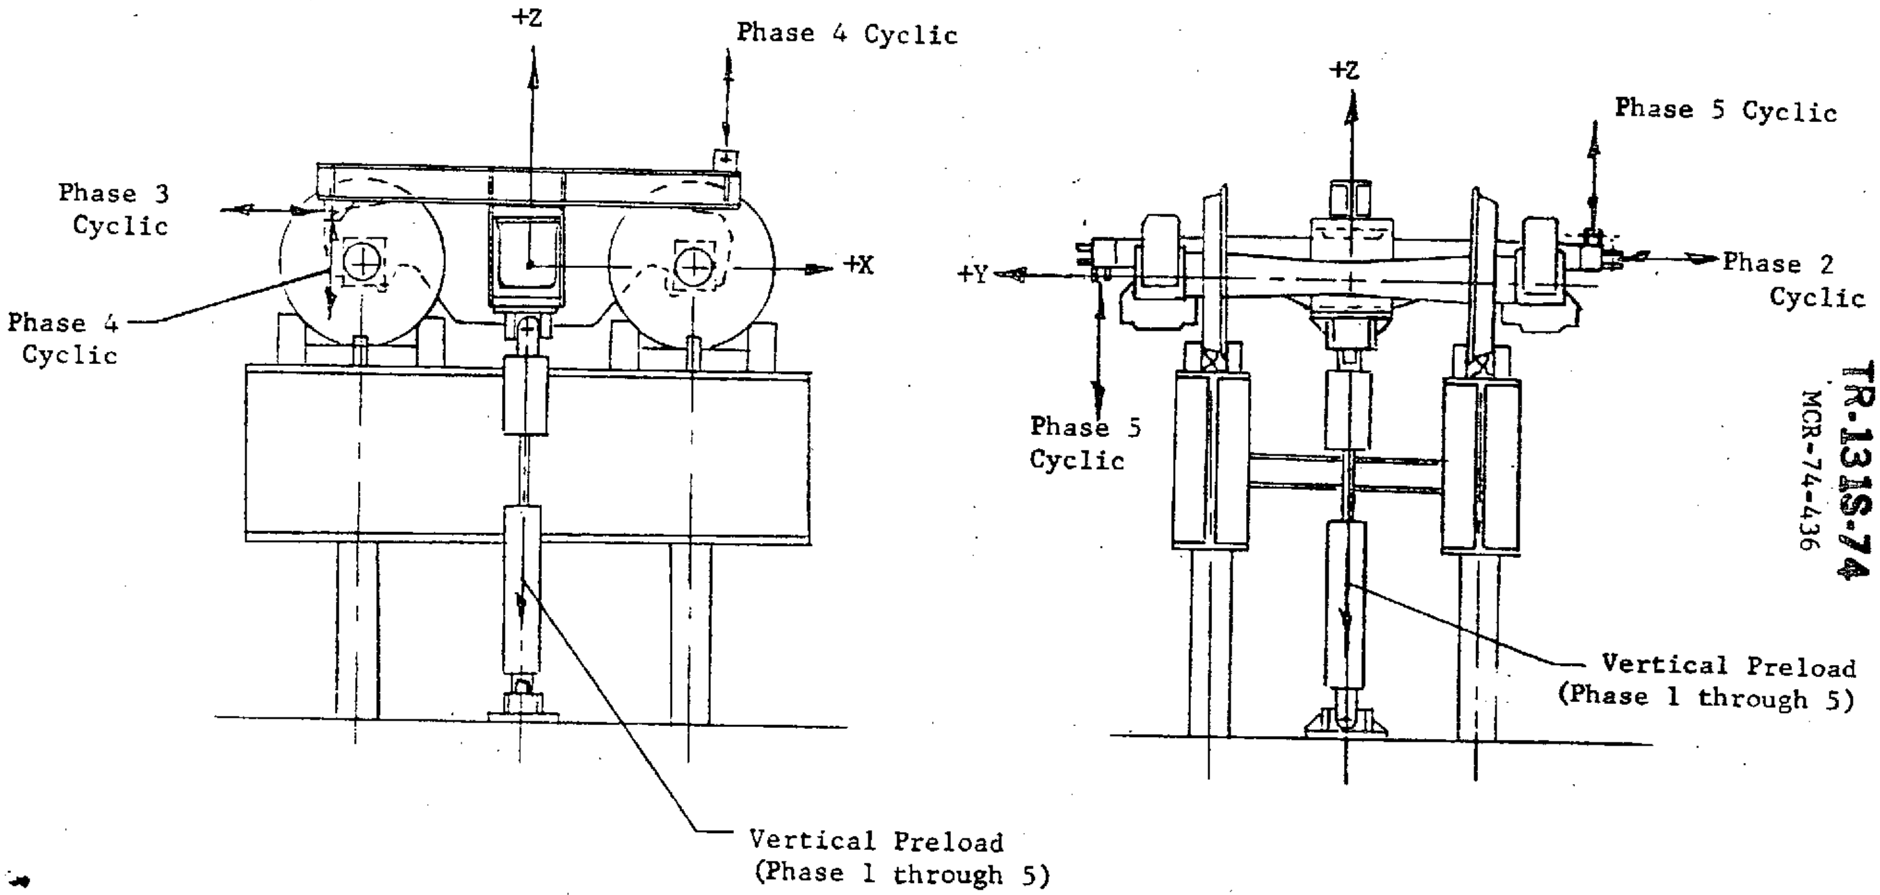
The vertical preload will be varied for all test phases with values of 20,000, 50,000 and 100,000 pounds being applied, and two cyclic loading runs conducted at each preload level. This will result in six load conditions for each phase of testing.

1.4 Test Instrumentation - Linear variable deflection transducers (LVDT) and structures lab deflection boxes (SLDB) will be utilized to monitor the various deflections of the truck assembly. Figure 4 summarizes the deflection gage locations while Table 1 defines measurement direction, anticipated range, and relative deflection being measured.

1.4 (Continued)

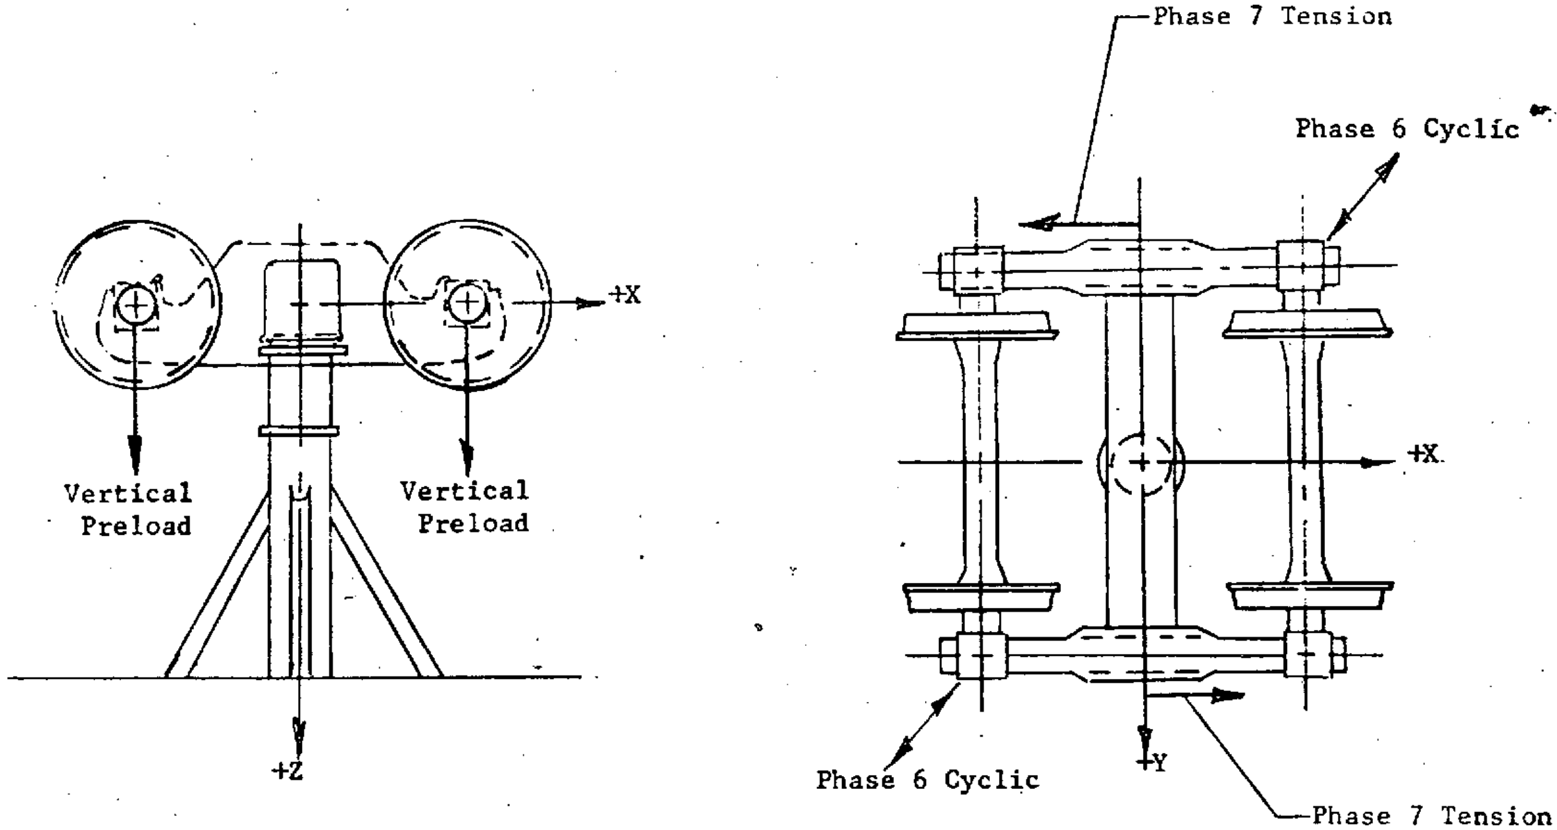
A Leeds and Northrup recorder will be used to provide a continuous polar plot of the vertical preload load line. The lateral and moment load lines will be controlled by a function generator that will be calibrated prior to each testing phase. Two Bristol Recorders will be used as back up data plots for the lateral and moment load lines.

The Central Data Recording IDS unit will be used to record deflection transducer and load cell output data on magnetic tape.



Note: See MMC Drawing LAB-1007045 for details of test setup.

Figure 1. Test Setup — Load Phase 1 Through Phase 5



Note: See MMC Drawing LAB-1007045 for details of test setup.

Figure 2. Test Setup - Load Phase 6 and Phase 7

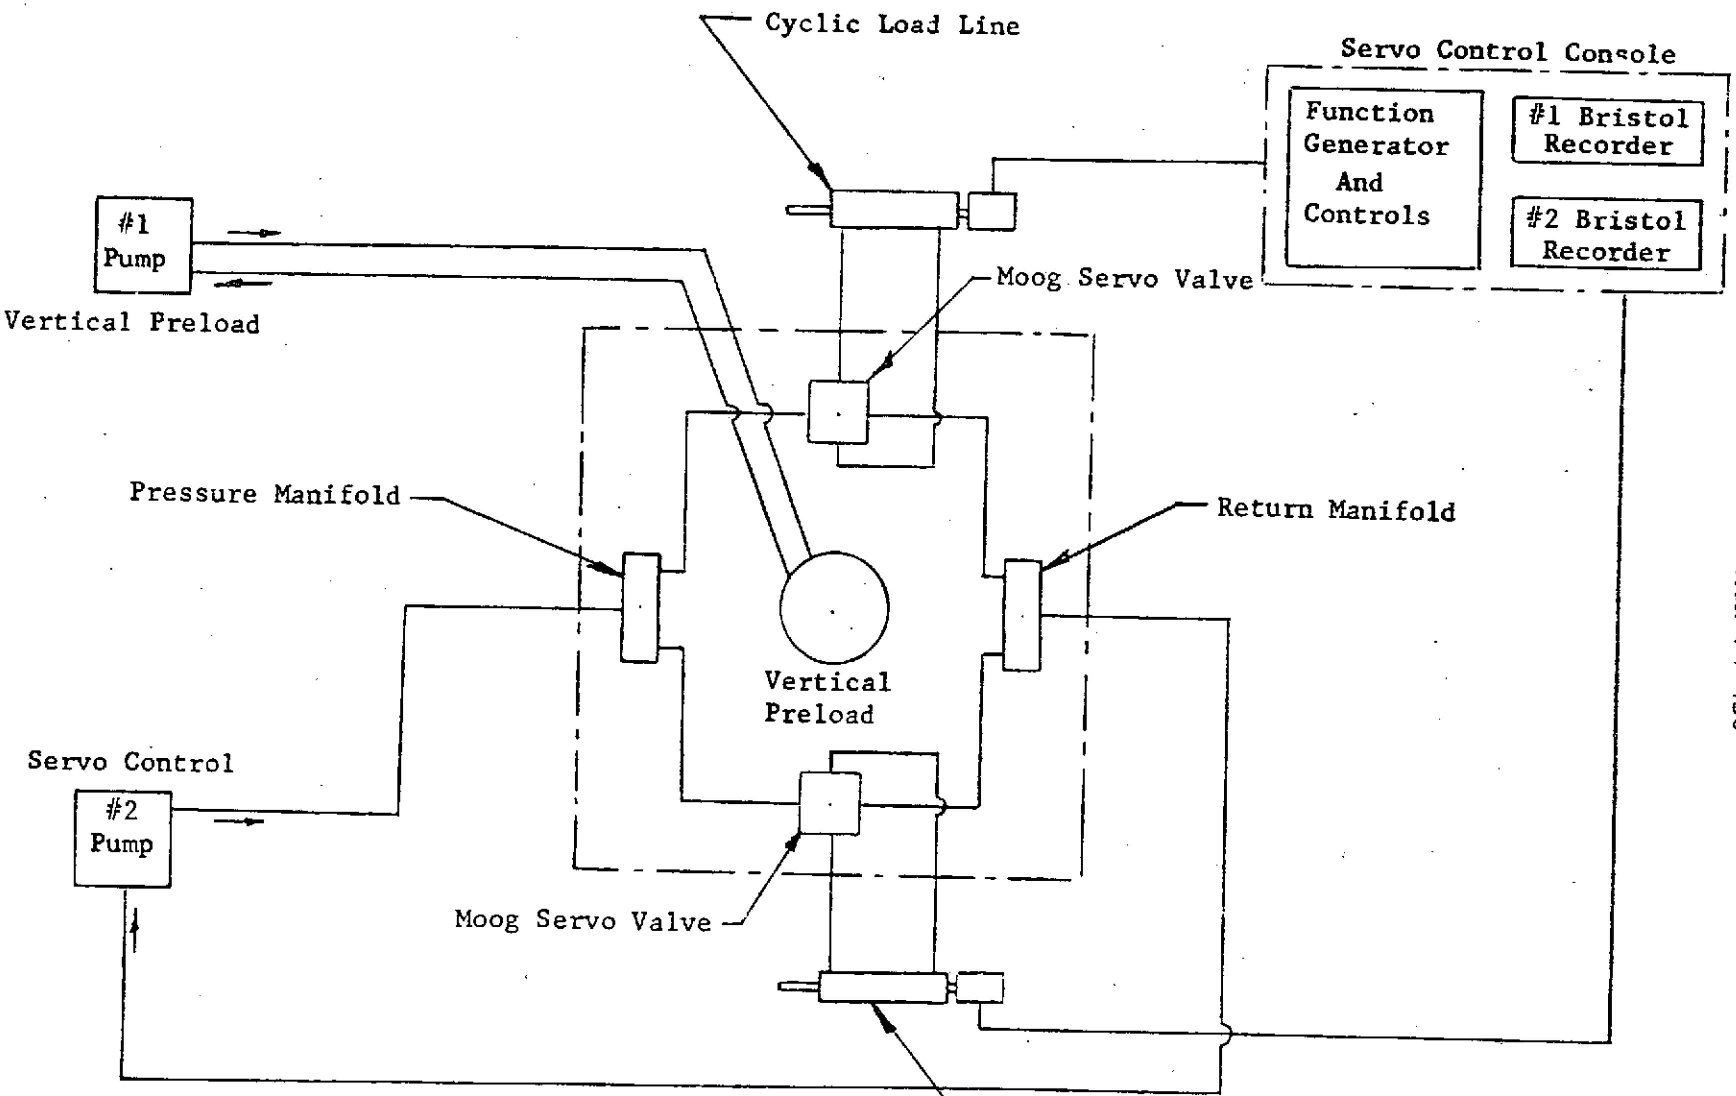


Figure 3. Servo Control and Hydraulic System Schematic

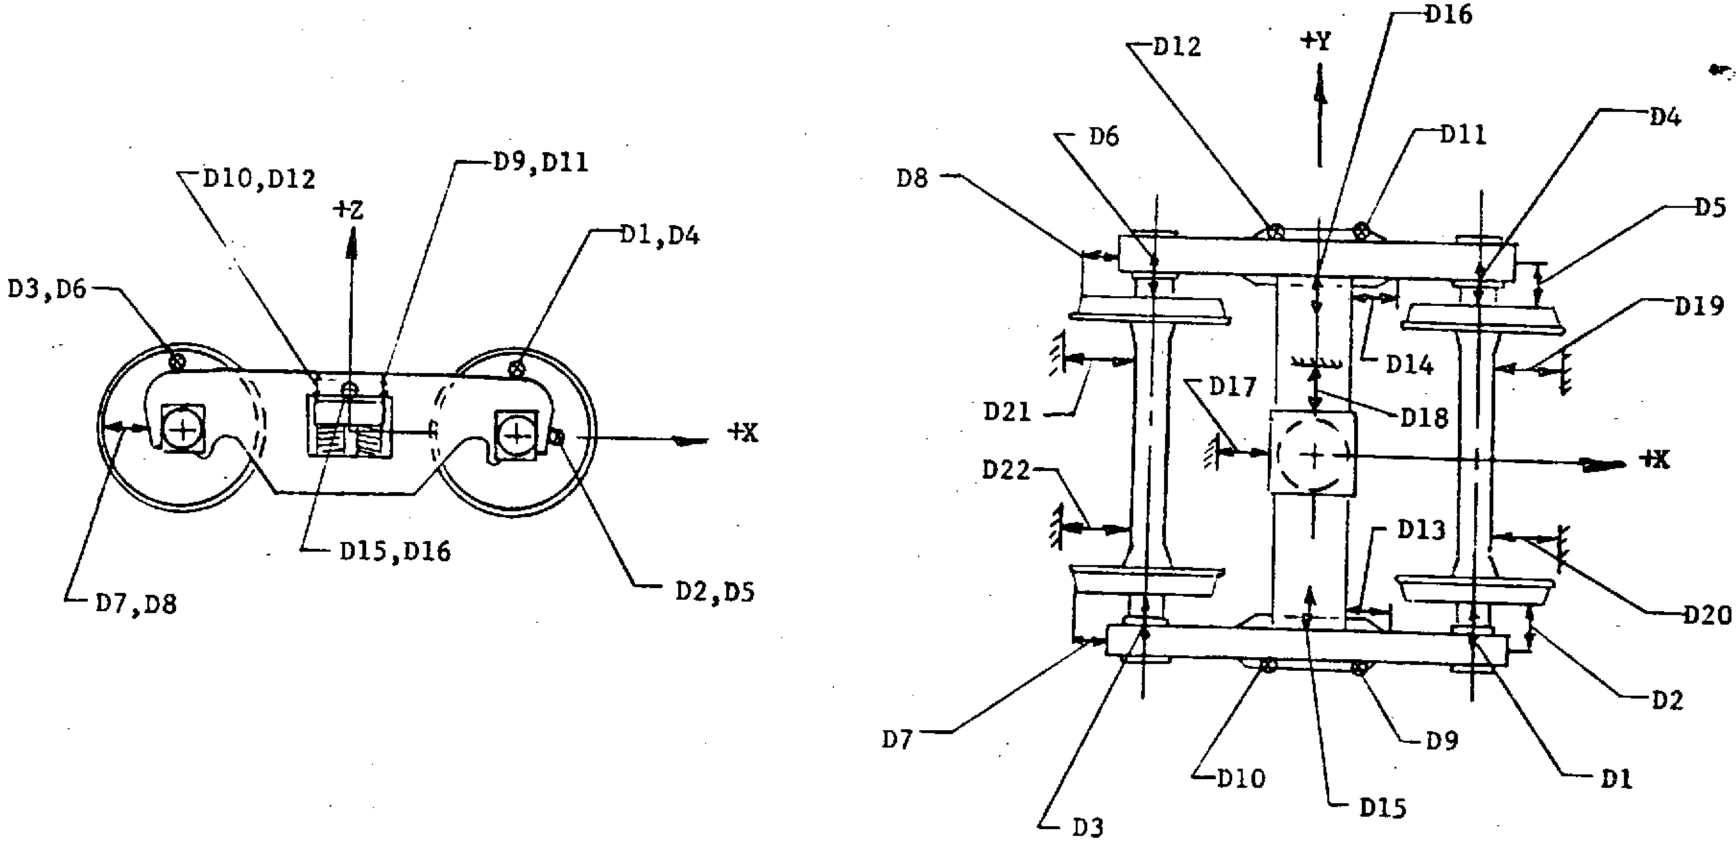

Figure 4. Ride Truck Deflection Transducer Requirements

Table 1. Deflection Transducer Summary (See MMC Drawing LAB1007045, Sh 11 for Phase 7)

GAGE	LOAD PHASE UTILIZED	RANGE/ DIRECTION	DESCRIPTION
D1,D2,D3 D4,D5,D6	1 to 6	± 1.0 Y	Sideframe Relative to Wheel/Axle
D7,D8	1 to 6	± 1.0 X	Sideframe Relative to Wheel/Axle
D9,D10 D11,D12	1 to 6	± 3.0 Z	Bolster Relative to Sideframes
D13,D14	1 to 6	± 1.0 X	Bolster Relative to Sideframes
D15,D16	1 to 6	± 1.0 Y	Bolster Relative to Sideframes
D17	1 to 5	± 1.0 X	Bolster Relative to Ground
D18	1 to 5	± 1.0 Y	Bolster Relative to Ground
D19,D20 D21,D22	6	± 3.0 X	Wheel/Axle Relative to Ground

1.5 Test Record - The progress of the test will be recorded in a written test log. The log will be prepared by the test engineer and will include all actions or events and the time of occurrence of the actions or events as deemed pertinent by the test engineer.

Photographs will be taken to document all test setups for all phases of testing. These photographs will become part of the test report.

Loading data will be manually recorded in the test log for each phase of testing.

1.6 Test Equipment List - The following equipment will be utilized during the phases of truck testing. Usage of the equipment is as defined on MMC drawing LAB 1007045 and this test procedure.

QTY	ITEM
1	200,000 pound Regent hydraulic jack
2	100,000 pound Regent hydraulic jack
2	50,000 pound Regent hydraulic jack

2	50,000 pound BLH load cell
2	20,000 pound BLH load cell
2	2,000 pound BLH load cell
12	Linear variable deflection transformer (± 1.00 inch)
10	Structure Laboratory Deflection Box (± 3.0 inch)
2	Bristol Recorder
1	Hydraulic pump no. 1
1	Hydraulic pump no. 2 (Servo control system)
4	Leeds and Northrup recorder
1	Function generator HP No. 3300A
2	Moog servo control valve - Model 73-234-SR13
1	Servo control console

1.6.1 Verify that all equipment and handling hardware are in calibration and will remain in calibration during testing.

2.0 TEST OPERATIONS

2.1 Preparations - Either truck assembly may be used for this test. The brake beams and linkages must be removed from the truck assembly prior to testing.

2.2 Pretest (Load Phases 1 through 5)

2.2.1 Verify the test area is ready for test aritcle and test fixture is fabricated per MMC Drawing LAB 1007045.

2.2.2 Install truck assembly in test fixture as defined on MMC Drawing LAB 1007045 for Load Phase 1.

2.2.3 Install all equipment associated with load line 1 as defined in MMC Drawing LAB 1007045.

2.2.4 Install deflection transducers as defined in Figure 1 of this test procedure and sheets 14 and 15 of MMC Drawing LAB 1007045. Record the dimensional coordinate location on Table 2.

2.2.5 Proof test Load Line 1 hydraulic system to a proof pressure of 1000 PSI above maximum operating pressure (Proof load to 6000 PSI tension load).

Table 2. Deflection Transducer Coordinate Location (Phase 1 through 5)
(Record after transducer installation)

* FOR PHASE 5 ONLY X = 0.00 IN

2.3 Sequential Operations (Load Phase 1)

1. Secure Low Bay Cell A test area per paragraph 3.1.
2. Review test personnel responsibility.
3. Verify Load cell and deflection transducer system calibration and zero setting.
4. Verify CDR readiness.
5. Record subzero data (Mag. tape and manual)
6. Increase hydraulic pressure on load line 1 until 20,000 pound tension load is maintained (theoretical pressure is 1000 PSI with L & N reading of 1.00).
7. Record 20,000 pound data (Mag. tape and manual).
8. Increase hydraulic pressure on load line 1 until 50,000 pound tension load is maintained (theoretical pressure is 2500 PSI with L & N reading of 2.50).
9. Record 50,000 pound data (Mag. tape and manual).
10. Increase hydraulic pressure on Load Line 1 until 75,000 pound tension load is maintained (theoretical pressure is 3,750 PSI with L & N reading of 3.75).
11. Record 75,000 pound data (Mag. tape and manual).
12. Increase hydraulic pressure on Load Line 1 Until 100,000 pound tension load is maintained (theoretical pressure is 5000 PSI with L & N reading of 5.00).
13. Record 100,000 pound data (Mag. tape and manual).
14. Start continuous CDR record (Mag. tape only).
15. Open hydraulic pressure line and let tension load reduce to zero.
16. Stop CDR record and allow Load Line 1 stabalize.
17. Record zero data (Mag. tape and manual).
18. Inspect truck assembly for any evidence of structural change.
19. Phase 1 loading complete.

2.4 Sequential Operations (Load Phases 2 and 3)

1. Proof Load, Load Line 2 to pressure of 1000 PSI above maximum operating pressure (proof load to 3000 PSI tension and compression).
2. Verify test setup is per MMC drawing LAB 1007045.
3. Secure Low Bay Cell A test area per paragraph 3.1.
4. Review test personnel responsibility.
5. Verify servo control system is ready for sine wave cyclic loading operation.
6. Verify load cell and deflection transducer system calibration and zero setting.
7. Verify CDR readiness.
8. Record subzero data (Mag. tape and manual).
9. Increase hydraulic pressure on Load Line 1 until 20,000 pound tension load is maintained (theoretical pressure is 1,000 PSI with L & N reading of 1.00) .
10. Activate servo control system to provide sine wave cyclic loading on load line 2 ± 10,000 pounds amplitude with a rate of 2.0 seconds/cycle.
11. Record 20,000 pound data (Mag. tape and manual).
12. Adjust servo control system to provide sine wave cyclic loading in load line 2 of ± 10,000 pounds amplitude with a rate of 4.0 seconds/cycle.
13. Record 20,000 pound data (Mag. tape and manual).
14. Increase hydraulic pressure in Load Line 1 until 50,000 pound tension load is maintained (theoretical pressure is 2,500 PSI with L & N ready of 2.50).
15. Adjust servo control system to provide sinewave cyclic loading On Load Line 2 of ± 10,000 pounds amplitude with a rate 4.0 seconds/cycle.
16. Record 50,000 pound data (Mag. tape and Manual).
17. Adjust servo control system to provide a sine wave cyclic loading load line 2 of ± 10,000 pounds amplitude with a rate of 2.0 seconds/cycle.

2.4 (Continued)

18. Increase hydraulic pressure in Load Line 1 until 100,000 pound tension load is maintained (theoretical pressure is 5,000 PSI with L & N reading of 5.00).
19. Adjust servo control system to provide sine wave cyclic loading on Load Line 2 of ± 10,000 pounds amplitude with a rate of 2.0 seconds cycle.
20. Record 100,000 pound data (Mag. tape and manual).
21. Adjust servo control system to provide a sinewave cyclic loading on Load Line 2 of ± 10,000 pounds amplitude with a rate of 4.0 seconds/cycle.
22. Record 100,000 pound data (Mag. tape and manual)
23. Reduce servo control system loads to zero.
24. Reduce hydraulic pressure in Load Line 1 to zero.
25. Record zero data (Mag. tape and manual).
26. Inspect truck assembly for any evidence of structural change.
27. Phase 2/Phase 3 loading completed.

2.5 Sequential Operations (Load Phase 4)

1. Proof load, load lines 2 and 3 to pressure of 1,000 PSI above maximum operation pressure (Proof Load to 1,400 PSI tension and compression).
2. Verify test setup is per MMC drawing LAB 1007045.
3. Secure Low Bay Cell A test area per paragraph 3.1.
4. Review test personnel responsibility.
5. Verify servo control system is ready for sine wave cyclic loading operation on Load Lines 2 and 3.
6. Verify load cell and deflection transducer system calibration and zero setting.
7. Verify CDR readiness.
8. Record subzero data (Mag. tape and manual)
9. Increase hydraulic pressure on load line 1 until 20,000 pound tension load is maintained (theoretical pressure is 1,000 PSI with L & N reading of 1.00).
10. Activate servo control system to provide sine wave cyclic loading on Load Lines 2 and 3 of ± 2,000 pounds amplitude with a rate of 2.0 seconds/cycle.
11. Record 20,000 pound data (Mag. tape and manual).
12. Adjust servo control system to provide sine wave cyclic loading on Load Lines 2 and 3 of ± 2,000 pounds amplitude with a rate of 4.0 seconds/cycle.
13. Record 20,000 pound data (Mag. tape and manual).
14. Increase hydraulic pressure on Load Line 1 until 50,000 pound load is maintained (theoretical pressure is 2,500 PSI with L & N reading of 2.50).
15. Adjust servo control system to provide sine wave cyclic loading on load lines 2 and 3 of ± 2,000 pounds amplitude with a rate of 4.0 seconds/cycle.
16. Record 50,000 pound data (Mag. tape and manual).
17. Adjust servo control system to provide sinewave cyclic loading on Load Lines 2 and 3 of ± 2,000 pounds amplitude with a rate of 2.0 seconds/cycle.
18. Record 50,000 pound data (Mag. tape and manual).

2.5 (Continued)

19. Increase hydraulic pressure on Load Line 1 until 100,000 pound load is maintained (theoretical pressure is 5,000 PSI with L & N reading of 5.00).
20. Adjust servo control system to provide sine wave cyclic loading on Load Lines 2 and 3 of ± 2,000 pounds amplitude with a rate of 2.0 seconds/cycle.
21. Record 100,000 pound data (Mag. tape and manual).
22. Adjust servo control system to provide sine wave cyclic loading on Load Lines 2 and 3 of ± 2,000 pounds amplitude with a rate of 4.0 seconds/cycle.
23. Record 100,000 pound data (Mag. tape and manual).
24. Reduce servo control system loads to zero.
25. Reduce hydraulic pressure in load line 1 to zero.
26. Record zero data (Mag. tape and manual).
27. Inspect truck assembly for any evidence of structural damage.
28. Phase 4 Loading complete.

2.6 Sequential Operations (Load Phase 5)

1. Proof load, load lines 2 and 3 to a pressure of 1,000 PSI above maximum operation pressure (Proof load to 2,600 PSI tension and compression).
2. Verify test setup is per MMC drawing LAB 1007045.
3. Secure Low Bay Cell A test area per paragraph 3.1.
4. Review test personnel responsibility.
5. Verify servo control system is ready for sine wave cyclic loading operation on Load Lines 2 and 3.
6. Verify load cell and deflection transducer system calibration and zero setting.
7. Verify CDR readiness.
8. Record subzero data (Mag. tape and manual).
9. Increase hydraulic pressure on load line 1 until 20,000 pound tension load is maintained (theoretical pressure is 1,000 PSI with L & N reading of 1.00).
10. Activate servo control system to provide sine wave cyclic loading on Load Lines 2 and 3 of ± 8,000 pounds amplitude with a rate of 2.0 seconds/cycle.
11. Record 20,000 pound data (Mag. tape and manual).
12. Adjust servo control system to provide sine wave cyclic loading on Load Lines 2 and 3 of ± 8,000 pounds amplitude with a rate of 4.0 seconds/cycle.
13. Record 20,000 pound data (Mag. tape and manual).
14. Increase hydraulic pressure on Load Line 1 until 50,000 pound load is maintained (theoretical pressure is 2,500 PSI with L & N reading of 2.50).
15. Adjust servo control system to provide sine wave cyclic loading on load lines 2 and 3 of ± 8,000 pounds amplitude with a rate of 2.0 seconds/cycle.
16. Record 50,000 pound data (Mag. tape and manual).
17. Adjust servo control system to provide sine wave cyclic loading on Load Lines 2 and 3 ± 8,000 pounds amplitude with a rate of 2.0 seconds/cycle.
18. Record 50,000 pound data (Mag. tape and manual).

2.6 (Continued)

19. Increase hydraulic pressure on Load Line 1 until 100,000 pound load is maintained (theoretical pressure is 5,000 PSI with L & N reading of 5.00).
20. Adjust servo control system to provide sine wave cyclic loading on Load Lines 2 and 3 of ± 8,000 pounds amplitude with a rate of 2.0 second/cycle.
21. Record 100,000 pound data (Mag. tape and manual).
22. Adjust servo control system to provide sine wave cyclic loading on Load Lines 2 and 3 of ± 8,000 pounds amplitude with a rate of 4.0 seconds/cycle.
23. Record 100,000 pound data (Mag tape and manual).
24. Reduce servo control system loads to zero.
25. Reduce hydraulic pressure in load line 1 to zero.
26. Record zero data (Mag. tape and manual).
27. Inspect truck assembly for any evidence of structural damage.
28. Phase 5 Loading complete.

2.7 Pretest (Load Phase 6)

2.7.1 Remove test fixture from cell A that was used for Phase 1 through 5 testing.

2.7.2 Verify test area is ready for test article and that test fixture is fabricated per MMC drawing LAB 1007045.

2.7.3 Install truck assembly on test fixture and equipment necessary to perform Phase 6 testing.

2.7.4 Verify installation of deflection transducers.

2.7.5 Record coordinate dimensions of deflection transducers on Table 3.

Table 3. Deflection Transducer Coordinate Location - Phase 6
(Record after transducer installation)

2.8 Sequential Operations (Load Phase 6)

1. Proof load the load line to 1000 PSI above maximum operating pressure. (Proof load, load lines 1 and 2 to 6000 PSI tension and load lines 3 and 4 to 3000 PSI tension and compression).
2. Verify test setup is per MMC drawing LAB 1007045.
3. Secure Low Bay Cell A test area per paragraph 3.1.
4. Review test personnel responsibility.
5. Verify servo control system is ready for sine wave cyclic loading operation on load lines 3 and 4.
6. Verify load cell and deflection transducer system calibration and zero setting.
7. Verify CDR readiness.
8. Record subzero data (mag. tape and manual).
9. Increase hydraulic pressure on load lines 1 and 2 until 10,000 pound tension load is maintained on each (theoretical pressure is 1000 PSI with L & N readings of 2.00).
10. Activate servo control system to provide sine wave cyclic loading on load lines 3 and 4 of ± 10,000 pounds amplitude with a rate of 2.0 seconds/cycle.
11. Record 20,000 pound data (mag. tape and manual).
12. Adjust servo control system to provide sine wave cyclic loading on load lines 3 and 4 of ± 10,000 pounds amplitude with a rate of 4.0 seconds/cycle.
13. Record 20,000 pound data (mag. tape and manual).
14. Increase hydraulic pressure in load lines 1 and 2 until 25,000 pound tension load is maintained in each. (Theoretical pressure is 2,500 PSI with L & N reading of 5.00).
15. Adjust servo control system to provide a sine wave cyclic loading on load lines 3 and 4 of ± 10,000 pounds amplitude with a rate of 4.0 seconds/cycle.
16. Record 50,000 pound data (mag. tape and manual).
17. Adjust servo control system to provide a sine wave cyclic loading on Load Lines 3 and 4 of ± 10,000 pounds amplitude with a rate of 2.0 seconds/cycle.

2.8 (Continued)

18. Record 50,000 pound data (mag. tape and manual).
19. Increase hydraulic pressure in Load Lines 1 and 2 until 50,000 pound load is maintained on each (theoretical pressure is 50,000 PSI with L & N reading of 10.00).
20. Adjust servo control system to provide a cyclic loading on load lines 3 and 4 of ± 10,000 pounds amplitude with a rate of 2.0 seconds/cycle.
21. Record 100,000 pound data (mag. tape and manual).
22. Adjust servo control system to provide a cyclic loading on Load lines 3 and 4 of ± 10,000 pounds amplitude with a rate of 4.0 seconds/cycle.
23. Record 100,000 pound data (mag. tape and manual).
24. Reduce servo control system loads to zero.
25. Reduce hydraulic pressure to zero on Load Lines 2 and 1.
26. Record zero data (mag. tape and manual).
27. Inspect truck assembly for any evidence of structural change.
28. Phase 6 Loading completed.

2.9 Sequential Operations (Load Phase 7)

1. Proof Load the Load Lines to 1000 PSI above maximum operating pressure. (Proof Load, Load Lines 1 and 2 to 6000 PSI tension and Load Lines 3 and 4 to 2000 PSI tension).
2. Verify the test setup is per MMC drawing LAB 1007045 for Phase 7 testing.
3. Secure Low Bay Cell A test area per paragraph 3.1.
4. Review test personnel responsibility.
5. Verify hydraulic system is ready for Loading.
6. Verify Load Cell and deflection transducer system calibration and zero setting.
7. Verify CDR is ready for data record.
8. CDR record zero data (mag. tape and manual).
9. Increase hydraulic pressure on Load Lines 1 and 2 until 10,000 pound tension load is maintained on each (theoretical pressure is 1000 PSI with L&N reading of 2.00).
10. CDR record 20,000 pound load data (Mag. tape and manual).
11. Increase hydraulic pressure on Load Lines 3 & 4 until 50.0 pound tension load is maintained (theoretical pressure is 50 PSI with L&N readings of 0.1).
12. CDR record 20,000 pound vertical tension load with 50.0 pound lateral tension loading data (Mag. tape and manual).
13. Verify hydraulic system is ready for continuous Loading.
14. Verify CDR is ready for continuous recording.
15. Start CDR continuous record (Mag. tape only).
16. Increase hydraulic pressure continuously in Load Lines 3 & 4 until bolster rotation is observed.
17. Stop hydraulic pressure loading.
18. Stop CDR continuous recording.
19. Reduce hydraulic pressure on Load Lines 3 & 4 to zero.
20. Reduce hydraulic pressure on Load Lines 1 & 2 to zero.
21 Manually relocate ride truck assembly to start position.
22. CDR zero out all deflection transducers.
23. Repeat steps 8 through 22 three times.

2.9 Sequential Operations (Load Phase 7) (Cont)

24. Increase hydraulic pressure on Load Lines 1 & 2 until 25,000 pound tension Load is maintained on each (theoretical pressure is 2500 PSI with L&N readings of 5.00).
25. CDR record 50,000 pound loading data (Mag. tape and manual).
26. Increase hydraulic pressure on Load Lines 3 & 4 until 50.0 pound tension Load is maintained (theoretical pressure is 50 PSI with L&N readings of 0.1).
27. CDR record 50,000 pound vertical tension Load with 50.0 pound Lateral tension loading (Mag. tape and manual).
28. Verify hydraulic system is ready for continuous loading.
29. Verify CDR is ready for continuous recording.
30. Start CDR continuous record (Mag. tape only).
31. Increase hydraulic pressure continuously on Load Lines 3 & 4 until bolster rotation is observed.
32. Stop hydraulic pressure loading.
33. Stop CDR continuous recording.
34. Reduce hydraulic pressure on Load Lines 3 & 4 to zero.
35. Reduce hydraulic pressure on Load Lines 1 & 2 to zero.
36. Manually relocate ride truck assembly to start position.
37. CDR zero out all deflection transducers.
38. Repeat steps 24 through 37 three times.
39. Increase hydraulic pressure on Load Lines 1 & 2 until 100,000 pound tension Load is maintained (theoretical pressure is 5000 PSI with L&N readings of 10.0).
40. CDR record 100,000 pound loading data (Mag. tape and manual).
41. Increase hydraulic pressure on Load Lines 3 & 4 until 50.0 pound tension load is maintained (theoretical pressure is 50 PSI with L&N readings of 0.1).
42. CDR record 100,000 pound vertical tension load with 50.0 pound lateral tension loading data (Mag tape and manual).
43. Verify hydraulic system is ready for continuous loading.
44. Verify CDR is ready for continuous recording
45. Start CDR continuous record (Mag tape only).

2.9 Sequential Operations (Load Phase 7) (Cont)

46. Increase hydraulic pressure continuously or Load Lines 3 & 4 until bolster rotation is observed.
47. Stop hydraulic pressure loading
48. Stop CDR continuous recording.
49. Reduce hydraulic pressure on Load Lines 3 & 4 to zero.
50. Reduce hydraulic pressure on load Lines 1 & 2 to zero.
51. Manually relocate ride truck assembly to start position.
52. CDR zero out all deflection transducers.
53. Repeat steps 39 through 52 three times.
54. Inspect ride truck assembly for evidence of structural damage.
55. Phase 7 Loading completed.

3.0 SPECIAL CONSIDERATIONS

3.1 Safety - The safety personnel will be notified of the test start a minimum of 24 hours prior to test start. Immediately prior to test start, the test area will be secured to prevent access of personnel by accomplishing the following:

a. Inform personnel in structures lab of testing.
b. Rope off test area around Cell A.
c. Close door between low bay and equipment storage room.
d. Close door between low bay and high bay.

In the event of a catastrophic failure, the Security Department will be notified to maintain the area during the following evaluation period.

3.1.1 Martin Marietta Corporation supervisors are responsible for the safety of all personnel, safe working conditions, and the implementation of all applicable safety requirements.

3.1.2 All test team members and observers are responsible for adhearing to normal safety standards and procedures. They are also responsible for advising the test engineer of any unsafe acts or conditions observed during preparation for or conduct of dry testing.

3.2 Facility Power Failure - In the event of a facility power failure, the applied hydraulic loading is locked in must be reduced manually. An existing emergency power supply is automatically activated and provides power to load readout console.

3.3 Test Setup/Specimen Failure - In the event of a suspected failure during the test, the applied hydraulic loading will be reduced to zero by means of manually operated controls. Photographs of all failures will be taken and refined.

3.4 Test Personnel Required for Conduct of Test

1. Structures Laboratory

Test supervisor
Test engineer
L & N console
Servo control system
Hydraulic pumps 1 and 2

3.4 (Continued)

2. Dynamics - Integration of Specimen behavior and test requirement decisions.

3. Central Data Recording - Monitor IDS console and take data.

4. Safety (By notification)

3.5 General

1. Applied hydraulic loading may be reduced at any time during performance of the test at the discretion of the test engineer. All recycles of the test load shall be entered in the test log.

2. The sequence of testing shall be up to the discretion of the test engineer.

4.0 APPENDIX - TEST LOG

4.1 Test Log Sheets

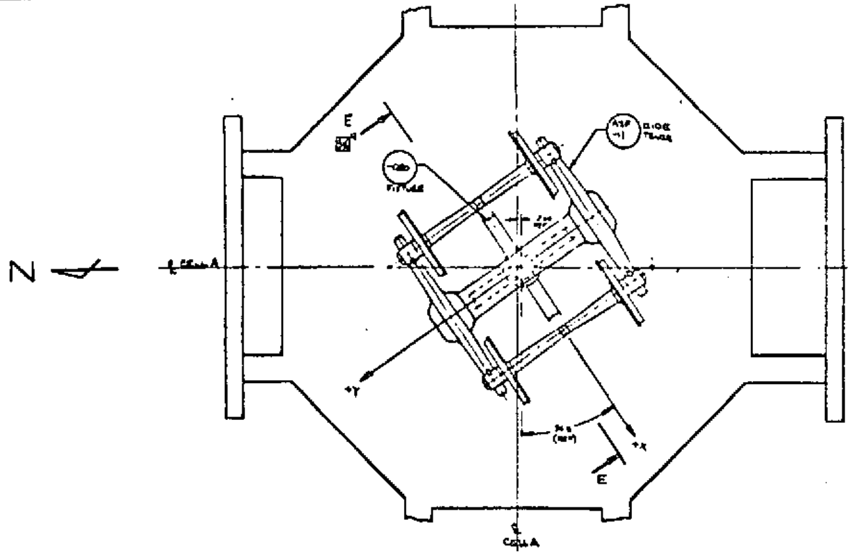
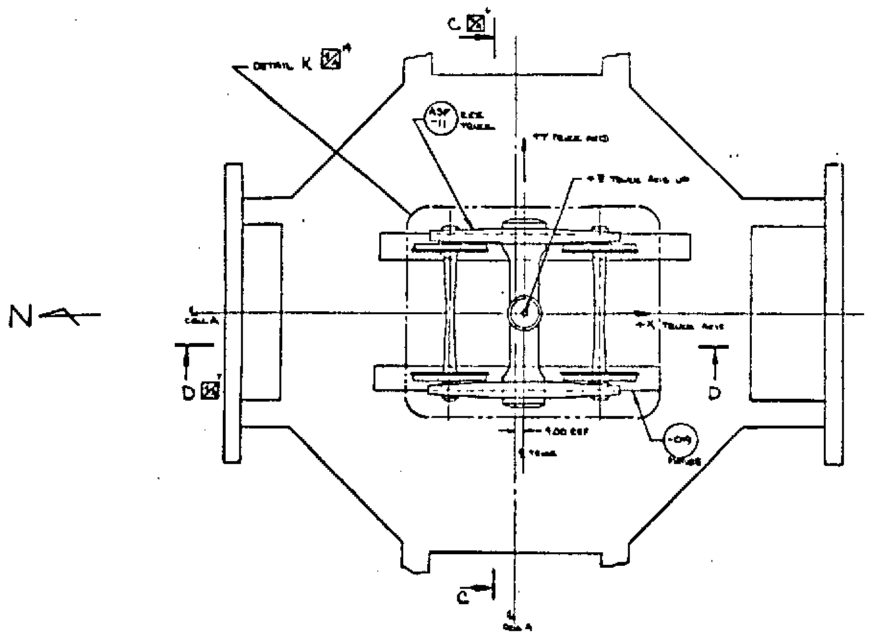
APPENDIX B



-010 ASSEMBLY
(LOAD PHASES 6 & 7)



-009 ASSEMBLY
(LOAD PHASES 1 THROUGH 5)

NOTE

1. ALL WELDS USE 70XX WELD ROD AND 1/4 INCH MINIMUM LEG UNLESS OTHERWISE NOTED. WHEN WELDING ON SIDE TRUCK ASSEMBLY ATTACH GROUND CLAMP TO WELD AREA TO PREVENT ARCING ACROSS BEARINGS.
2. SEE SHEET 19 FOR NOTES ON DEFLECTION TRANSDUCERS.
