16. Abstract

Thermodynamic data are required input for the finite kinetics and equilibrium computer programs needed for modeling the combustion of hydrocarbons in the fields of energy and pollution research. Least squares determined coefficients of the curve-fitted thermodynamic data for 193 species in the C-H-O-N system are presented in card image form of suitable format for use by the commonly used computer programs.

SUMMARY

The thermochemical data for the 179 chemical species presented by Bahn (NASA CR2178) for the C-H-O-N System have been curve-fitted to provide coefficients used as input data for equilibrium and finite chemistry computer programs such as Gordon and McBride (NASA SP-273), Bittker and Scullin (NASA TN D6586), and Pratt (Washington State University Bulletin 336). Polynomial coefficients are listed in the proper card image form for use in these computer programs. The thermochemical curve-fit coefficient data include many chemical species which are not included in the present data tapes used with the referenced computer programs. Hydrocarbon reaction mechanisms that were previously neglected because of lack of thermochemical data can now be included in combustion and pollutant formation analytical studies.

INTRODUCTION

In efforts to utilize the dwindling supply of hydrocarbon fuels in a more efficient way and in a manner less destructive to the environment, the use of computer combustor models as engineering tools to guide the development of combustion systems will be increasing. Realistic chemical reaction mechanisms describing the pyrolysis and subsequent oxidation of various hydrocarbon fuels and fuel mixtures are very important in combustor modeling. As more detailed reaction mechanisms are developed, a need arises for thermochemical data for the various hydrocarbon fuels and combustion intermediates. These data are used to assemble the complex reaction mechanisms that are required to describe the combustion of hydrocarbon fuels and the formation of pollutants. The need for thermochemical data becomes increasingly important as attempts are made to use fuels synthesized from coal or shale oil, where fuel

chemical structure may be an important factor in its combustion and pollutant formation characteristics.

The JANNAF tables (ref. 1) have provided thermochemical data for many of the lower molecular weight hydrocarbons and pyrolysis intermediates for combustion calculations in the past. However, thermochemical properties of the larger molecular weight hydrocarbons, which are the predominant constituents of present-day fuels, have been omitted from consideration. One reason for the omission has been the orientation of the efforts of the JANNAF organization toward tabulating thermochemical data primarily for the combustion products of rocket engines. Nevertheless, some numerical representation of the chemical thermodynamics of the higher molecular weight hydrocarbons is required if they are to be considered quantitatively in combustion kinetics.

A recent report by Bahn (ref. 2) provides approximate thermochemical properties for a number of the higher molecular weight fuels and intermediate species which may result from their pyrolysis. It is believed that, during the interim period until a recognized body such as the JANNAF organization compiles thermochemical data for these species, the data provided by Bahn can be used to upgrade computational procedures involving more complex reaction mechanisms in combustion models.

The compilation of Bahn presents thermochemical data for entropy, heat capacity, and enthalpy to temperatures of 6000°K in tabular form much like that of the JANNAF tables. The tables as issued by Bahn were prepared using the computer program of McBride and Gordon (ref. 3). This program creates least squares polynomial fit coefficients to express the pertinent thermochemical data as functions of temperature. Bahn used the program to smooth interpolated and extrapolated data. Being interested in applying the output of smoothed

tabular data, consistent with the data format of computer program FINEK*, he did not report the polynomial coefficients which had been created. The present work comprises a restoration of the coefficients from the smoothed tables presented by Bahn.

While the form of Bahn's data is convenient for observing the trends of the data or for comparing it with existing data, it is in a form not easily compatible with most existing computational models other than program FINEK. A number of computer programs now available for performing combustion calculations with either equilibrium or kinetically controlled chemistry rely on "packed" thermochemical data. The "packed" data are in the form of the least squares polynomial fit coefficients from which thermochemical properties can be calculated at required temperatures. To be more specific, the computer programs of Gordon and McBride (ref. 4), Bittker and Scullin (ref. 5), and Pratt (ref. 6), all of which deal with combustion of fuels, require the thermochemical data in the "packed" form. Therefore, in the present work, the thermochemical data of Bahn have been curve-fitted by the method of McBride and Gordon (ref. 3) and the coefficients are presented in the card form suitable for use with the specified computer programs or any other programs using the method of Gordon and McBride to calculate thermochemical properties.

A comparison is shown for the combustion of methane and air with the perfectly stirred reactor program of Pratt (ref. 6) using the original "packed" thermochemical data supplied by Gordon and McBride derived from the JANNAF tables and the "packed" thermochemical data derived from Bahn's tables. This comparison was performed to check the consistency between the two versions of thermochemical data during an actual combustion calculation. To illustrate the use of the new thermochemical data, a perfectly stirred reactor calculation

---

*Program FINEK was created at the Marquardt Company by A. Widowsky and C. W. Brandenburg and used by Bahn both there and at LTV Aerospace Corporation for general finite-kinetics calculations.

of propane-air stoichiometric combustion was performed. The reaction mechanism for this calculation was a combination of the complex Chinitz-Baurer mechanism (ref. 7) and an accepted methane combustion mechanism (ref. 8), and involves many of the species previously neglected because of lack of thermochemical data.

SYMBOL LIST

C_p	heat capacity, constant pressure
h	enthalpy
$\dot{m}$	mass flow rate, $\frac{\text{gram}}{\text{sec}}$
R	universal gas constant
S	entropy
T	absolute temperature
v	volume, cc

CALCULATION OF COEFFICIENTS

The polynomial coefficients were calculated using the computer program of McBride and Gordon (ref. 3). The tabular thermochemical data issued by Bahn (ref. 2) were used to effect a simultaneous least squares polynomial fit of C_p/R, h/RT, and S/R in the form

$$\frac{C_p}{R} = A_1 + A_2T + A_3T^2 + A_4T^3 + A_5T^4$$

$$\frac{h}{RT} = A_1 + \frac{A_2}{2}T + \frac{A_3}{3}T^2 + \frac{A_4}{4}T^3 + \frac{A_5}{5}T^4 + \frac{A_6}{T}$$

$$\frac{S}{R} = A_1 \ln T + A_2T + \frac{A_3}{2}T^2 + \frac{A_4}{3}T^3 + \frac{A_5}{4}T^4 + A_7$$

where C_p is defined as heat capacity at constant pressure, h is enthalpy-based at the reference temperature of 298.15°K, S is entropy, R is universal gas constant, and T is temperature. The seven coefficients ($A_1 \cdots A_7$) calculated by the program for the upper (1000-5000°K) and lower (300-1000°K)

temperature ranges of the thermochemical data are presented in the card format suitable for use by the computer programs of references 4, 5, and 6. The format is as follows:

(a) Card 1 (Contains species name, reference, pertinent elemental symbols and stoichiometric coefficients, the temperature range, and the card number).

Columns 1 - 8	Species name
Columns 19 - 24	Reference
Columns 25 - 44	Elemental symbols and stoichiometric coefficients
Columns 45	State of species
Columns 49 - 55	Lowest temperature
Columns 58 - 65	Highest temperature
Column 80	Number of card

(b) Cards 2 through 4 (Contain coefficients ($A_1 \cdots A_7$) for the upper temperature range followed by coefficients ($A_1 \cdots A_7$) for the lower temperature range).

Card 2,	Columns 1 - 15	A_1	Upper Temperature Range
	Columns 16 - 30	A_2	
	Columns 31 - 45	A_3	
	Columns 46 - 60	A_4	
	Columns 61 - 75	A_5	
Card 3,	Columns 1 - 15	A_6	
	Columns 16 - 30	A_7	
Card 3,	Columns 31 - 45	A_1	
	Columns 46 - 60	A_2	
	Columns 61 - 75	A_3	

Card 4,	Columns 31 - 45	A_4	Lower Temperature Range
	Columns 16 - 30	A_5	
	Columns 31 - 45	A_6	
	Columns 46 - 60	A_7	

Each species is represented by a four-card set.

The cards were stored on a tape in the same manner as the original tape supplied by Gordon and McBride (ref. 4). The data of this form stored on a tape have been referred to as "packed" thermochemical data. The cards are listed in Appendix A, pages A1 - A14, for the Bahn data. The cards on page A15 (also last set on page A14) of the Appendix were added from the original data as reported in (ref. 4) to make a more complete C-H-O-N thermochemical package. In the case of species common to both data sets, the Bahn data were chosen for the present listing in order to provide a more unified data set, with the exception of water for which the listing of the two phases of the JANNAF data set was considered more appropriate.

RESULTS OF CALCULATIONS

Application of the species provided by Bahn and the curve fits reported here to the computer programs of ref. 4, 5, and 6 requires only slight modification of the different programs. Methane-air combustion calculations were performed using the stirred reactor computer program of ref. 6 and the methane mechanism from Jachimowski (ref. 8) with the original thermochemical data tape from Gordon and McBride as well as with the thermochemical data tape of this paper.

Figure 1 shows the variation of mole fractions of CO and NO with residence time within the reactor volume. The circular symbols represent a calculation using the original [old] tape and the square symbols represent a calculation performed using the [new] tape generated in this paper. The variation of

temperature with mass flow rate for methane-air combustion is shown in Figure 2 for the old and new thermochemical data tapes. These figures illustrate that although the curve-fitted polynomial coefficients listed in reference 4 appear different from those listed in Appendix A for the same species considered in the methane-air calculation, the results such as mole fractions of the chemical species and the temperature variation with mass flow rate per unit volume are comparable.

To illustrate the need for thermochemical data provided by Bahn and curve-fitted in this paper, a computer calculation of propane-air combustion was performed using a complex reaction mechanism. The reaction mechanism, which is a combination of the Chinitz-Baurer Mechanism (ref. 7) and an accepted methane reaction mechanism (ref. 8), is shown in Table I. This composite reaction mechanism contains many of the intermediate species for which thermochemical data in the form of polynomial coefficients were not previously available. The equilibrium combustion solution for the polynomial fits generated in this paper is shown in Table II. In Table III, the mole fractions of the combustion products at different stirred reactor stationary states are shown. As was stated earlier, this stirred reactor combustion solution was provided as an example of the type of reaction mechanism that may now be considered. Perhaps a more vivid example of the need for this interim thermochemical data is the fact that not even the simplest propane combustion calculations could be tested previously because as yet the JANNAF tables do not include propane.

CONCLUDING REMARKS

Least square polynomial coefficients for 179 species in C-H-O-N system have been calculated from the thermochemical data presented by Bahn in NASA CR-2178. These thermochemical data coefficients, along with some taken from NASA SP-273 which were not in the Bahn list of species, are presented in a

form suitable for use with equilibrium and finite rate chemistry computer programs such as those described in NASA SP-273, NASA TN D-6586, and Washington State University Bulletin 336. The thermochemical data provided by Bahn and for which polynomial curve-fit coefficients are listed in this report allow use of complex hydrocarbon species - important for combustion analyses - but missing from present compilations such as the JANNAF Tables. Results of calculations with species included in the thermochemical data coefficients listed in NASA SP-273 and those listed in this compilation agree very well. Results of the propane-air combustion could not be compared with the data of NASA SP-273 because no data for propane or its pyrolysis intermediates were included therein.
