ABSTRACT

A small-scale wind tunnel test of a two engine hybrid model with upper surface blowing on a simulated expandable duct internally blown flap was accomplished in a two phase program. The low wing Phase I model utilized 0.126c radius Jacobs/Hurkamp flaps and 0.337c radius Coanda flaps. The high wing Phase II model was utilized for continued studies on the Jacobs/Hurkamp flap. Principal study areas included: basic data both engines operative and with an engine out, control flap utilization, horizontal tail effectiveness, spoiler effectiveness, USB nacelle deflector study and USB/IBF pressure ratio effects.

SYMBOLS

General Notation

AR	Aspect ratio, b ² /S
b	Wing span, centimeters (inches)
BLC	Boundary layer control
c	Chord, centimeters (inches)
ē, MAC	Mean aerodynamic chord, centimeters (inches)
с _D	Drag coefficient, drag
с _L	Lift coefficient, lift qS
Cm _{ē/4}	Pitching moment coefficient about 0.25c, pitching moment qSc
C _n	Yawing moment coefficient, yawing moment qSb
с _R	Rolling moment coefficient, rolling moment qSb
с _т	Thrust coefficient, static gross thrust qS
Су	Side force coefficient, $\frac{\text{side force}}{qS}$
IBF	Internally blown flap
FA	Axial force, N (lb)
F g	Gross thrust from calibration, N (Ib)
F _N	Normal force, N (lb)
F _R	Resultant force $\sqrt{F_A^2 + F_N^2}$, N (1b)
J/H	Jacobs/Hurkamp
L [']	Left side operative
PR	Pressure ratio, total pressure/tunnel static pressure
q	Freestream dynamic pressure, N/square meter (lb/square foot)
R	Right side operative
S	Wing area, square meters (square feet)

xviii

General Notation (Continued)

.

×	Chordwise station, centimeters (inches)
У	Spanwise station, centimeters (inches)
z	Vertical distance from wing chord plane, centimeters (inches)
X	Fuselage reference line angle of attack, degrees
3	Angle of sideslip, – Ψ , degrees
8;	Jet deflection angle, $\tan^{-1}F_N/F_A$ degrees
-3 Ψ	Angle of yaw of plane of symmetry, degrees
n	Spanwise position, $\frac{2y}{b}$
η_{f}	Flap static turning efficiency, F _R /F _g

Model Notation

в	Fuselage. C-141 modified.
Ь	Bullet.
D ²	Dorsal. Free faired dorsal to approximate lines of EBF QUESTOL.
E3	Aspect ratio 4.0 nozzle with center and edge bodies.
f ^{23c} x	Leading edge flap. 17 percent local wing chord, cambered and cut out for USB nacelles. Deflection from stowed position normal to hinge line denoted by subscript x.
f ³³ ×	Main Jacobs/Hurkamp flap. Nominal streamwise deflection angles denoted by x.
f ³⁴ x	Auxiliary Jacobs/Hurkamp control flap. Nominal streamwise deflection angles denoted by x.
f ³⁵ ×	Main Coanda flap nominal trailing edge upper surface deflection angles denoted by \times .
H_{x}^{2}	Horizontal stabilizer. Deflections denoted as subscript x.
N _x ¹²	Nacelles. Aspect ratio 4.0 slot nozzles. Nominal nacelle exit placement in percent local chord denoted by subscript x.
s ¹	$S^2 plus D^2 V^2 b^1$.
s ²	$B^{1A}W^2f_x^{23c}Z^{w1}$ (high wing) or $B^{1A}W^1f_x^{23c}Z^{w2}$ (low wing).

.

SUMMARY

An investigation has been conducted to determine the aerodynamic characteristics of a small scale model with a hybrid propulsive lift system. The hybrid concept represents a combination of the upper surface blowing (USB) system with the internally blown flap (IBF) to augment lift and provide control. The model was tested in low and high wing configurations in Phase I and Phase II programs, respectively. The wing sweep at the quarter chord was 30 degrees on the low wing model and 15 degrees on the high wing. Results were obtained for a variety of nacelle exit nozzle configurations in combination with two simulated expandable duct trailing edge flap systems, (1) the basic flap with knee radius 12.6 percent local chord and blowing at the knee and trailing edge, and (2) the Coanda flap with knee radius 33.7 percent local chord and blowing at the trailing edge only. Results were obtained for several flap deflections at nominal thrust coefficients from 0 to 3.0. Selected six-component longitudinal, lateral and directional data are presented with two engines operating and with an engine out.

Proper nacelle exit tailoring made the efficient utilization of the basic small radius flap possible. A maximum lift coefficient of 9.55 at a thrust coefficient of 3.0 was obtained with this small radius IBF surface and two USB nacelles equipped with 10 degree exit deflectors.

INTRODUCTION

The hybrid propulsive lift concept represents a combination of two high lift systems which utilize external blowing on the wing upper surface and internal blowing from the wing flap. Earlier independent investigation of these two systems is reported in reference 1 for the upper surface blowing (USB) concept and in reference 2 for the internally blown flap (IBF) concept. Both systems hold promise and are currently being considered independently in selected STOL transport designs. The upper surface blowing system depends upon the Coanda effect to turn engine jet exhaust and/ or fan discharge air over the flap, and possesses possible noise advantages. The internally blown flap offers high aerodynamic efficiency with control of the boundary layer in conjunction with power transfer to reduce engine-out asymmetry. The use of large quantities of low pressure air requires large flow areas, and both of the hybrid systems investigated in the tests reported herein would utilize expanding internally blown flaps on the airplane. The Jacobs/Hurkamp (J/H) flap provides large flow areas for spanwise internal flow, but allows compact stowing of the flap in the clean configuration. The J/H flap attains increased internal flow area with flap deflection by proper location of the flap upper and lower surface hinge lines. The Coanda flap concept for this test also provides expanding area in a fashion similar to that of the J/H flap, but also requires a flexible upper surface in order to provide the large flap leading edge radii.

The obvious complimentary nature of the USB and the IBF systems pointed to the need to investigate the hybrid concept. This investigation was undertaken in the Lockheed V/STOL Wind Tunnel in a two phase program. The Phase I program was initiated in September, 1973, and 158 runs were secured. The Phase II program followed in November, 1973 with 242 runs. Results were obtained on small (J/H) and large (Coanda) radius flaps at several deflections with various nacelle exit configurations at thrust coefficients from zero to three. The Phase I data were obtained at Reynolds numbers from 0.137 to 0.308 million, based on a mean aerodynamic chord (MAC) of 0.31m and at dynamic pressures from 312.6 to 1393.2 N/m² (6.53 to 29.1 psf), respectively. Phase II results were obtained at slightly lower Reynolds numbers since the MAC was reduced to 0.29m.

MODEL

Figures 1 and 2 show the Phase 1 and 11 models installed in the 4.95 m (16.25 ft.) by 7.09 m (23.25 ft.) low speed test section of the Lockheed V/STOL Tunnel. The wing is located in the approximate center of the test section. Pertinent dimensional data for Phase I (low wing) and Phase II (high wing) models are given in table 1. The geometry of the basic models is shown in figures 3(a) and 3(b).

Wing

The Phase I wing had a quarter chord sweep of 30 degrees and aspect ratio of 6.5, while the Phase II wing sweep was reduced to 14.92 degrees and resulting aspect ratio of 7.73. Both models utilized the same physical wing set to the prescribed sweep angles. The basic airfoil was a Gelac TAC/STOL section with 0.125c thickness at the root and a linear taper to 0.095c at the tip. The ordinates of these sections are tabulated and plotted in table II.

Leading Edge Flaps

Full span 0.17c leading edge flaps were used to increase the stall angle of the models. The flap reference line was deflected down 60 degrees from the wing chord line. This was equivalent to a 110 degree deflection from the stowed position. The trailing edge of the lead ing edge device was placed forward of the basic airfoil nose 0.015c and up 0.005c perpendicular to the wing chord line. This gap and deflection of the leading edge flaps was maintained throughout the tests. Leading edge flap ordinates are tabulated and plotted in table 111.

Trailing Edge Flaps

The two trailing edge flap systems investigated are presented in figure 4. Both are the expanding-duct type to provide sufficient duct area to supply the trailing edge blowing. The basic flap studied was the Lockheed Jacobs/Hurkamp (J/H) type with a typical small ki radius of 0.126c. This flap system, with a 0.095c control flap at the trailing edge, was set in the aft 0.40c of the wing. The Coanda flap was formed by adding a larger radius

piece to the basic J/H flap upper surface. This increased the flap radius to 0.337c and overall length to 0.43c. Both flap systems on high and low wing configurations spanned approximately 60 percent of the wing. Trailing edge flap deflections from 22 to 60 degrees were set with selected control flap articulation giving an additional <u>+</u>30 degrees.

Spoilers

The Phase II model was equipped with 0.10c spoilers. These spoilers were deflected up from the wing surface 10, 20 and 30 degrees. Solid and porous types were investigated. The porous type had a 50 percent porosity with sections removed to give aspect ratio 1.0 tabs. Spoilers covered the full flap span, inboard half flap span, inboard quarter flap span and outboard half flap span. The part-span porous spoilers are pictured in figure 5.

Fuselage

The fuselage had a constant 25.908 cm (10.2 in.) diameter center section. Forward and aft fairings were added to give a total length of 206.726 cm (81.388 in.) and fineness ratio of 7.98. Overall contouring represents a typical transport fuselage with aft loading capability.

Tail

The empennage is also a typical STOL transport configuration with geometry detailed in table 1. The horizontal tail incidence was set at 0 degrees for all base runs and deflected from -5 to +10 degrees in selected cases.

Nacelles

Both Phase I and Phase II models represented two engine aircraft configurations. The installation of the nacelle on the wing with the J/H flap is presented in figure 6. The nacelles were powered pneumatically and each had 40.325 square cm exit area. The basic exit had an aspect ratio of 4.0 (width of 12.7 cm and height of 3.175 cm), and was nominally placed at 0.20c, 0.35c and 0.50c positions on the wing. The majority of the tests were performed at the nominal 0.35c position. The variety of exit tailoring devices

that were deployed are shown in figure 7. The zero degree deflector was utilized in the majority of the Phase I tests, and the 10 degree deflector was installed for the main portion of Phase II tests. The model nacelles had no inlet and therefore the test results do not include engine ram drag. All model blowing systems operated at a nominal pressure ratio of 1.5, unless otherwise noted.

TESTS

Table IV is an index to both Phase I and II investigations. Forces and moments were measured through an angle-of-attack range from -8 to 26 degrees, or through stall in Schedule "A", and yaw range from -20 to 20 degrees, at zero angle of attack in Schedule "B". An abbreviated pitch schedule to define zero-alpha and maximum lift was also run as Schedule "C". The wind tunnel dynamic pressure was varied from 312.6 N/m² (6.53 psf) to 1393.2 N/m² (29.1 psf) giving a Reynolds number range from 0.137 to 0.308 million. Nominal thrust coefficients from zero to three were set by these variations in dynamic pressure.

The thrust coefficients shown herein are the sum of the individual system $C_{T's}$ for each run. Note that this procedure results in an "installed" C_T , i.e., as measured including any scrubbing drag, but that side force components are excluded in that only the lift and drag forces are vectorially summed.

The distribution of blowing inputs was held to specific nominal levels during the principal tests. The individual exit areas were adjusted to provide the desired thrust split at the slot total pressures. Specified thrust coefficients were then obtained by varying the tunnel dynamic pressure. Configurations with equal pressure ratios at nacelle and knee blowing points produce a nominal thrust split of 95%/5%; the nacelle and trailing edge thrust split was 85%/15%; and blowing from nacelle, knee, and trailing edge was distributed 80%/5%/15%.

Static Tests

Static thrust calibrations for each of the nacelles were made on the wind tunnel balance, a separate calibration being determined for each nacelle exit configuration. Each low wing test nacelle had three total pressure probes located just inside the nozzle exit. These probes required continual repair, and the subsequent high wing tests utilized a modified two probe design. The nacelle thrust was set during the runs utilizing the appropriate curve of thrust versus nozzle pressure ratio. The nacelle thrust utilized in this report is the vectorially summed thrust as calibrated from the balance normal and axial forces with the wing trailing edge flaps set at zero degrees.

The thrust of each of the BLC systems was also obtained on the balance with concurrent measurement of the pressure ratio in the appropriate system. Each wing semispan included three total pressure probes in the knee BLC system and three in the trailing edge BLC system. These probes were located as close to the exit slots as space permitted in order to obtain slot total pressure with minimum achievable error. The BLC lift and (negative) drag components were then vectorially summed for each model configuration, and this sum was used in the calculation of $C_{\rm T}$.

Static tests were conducted in the wind tunnel with the wind off to determine the static jet angle and turning efficiency of each principal configuration. Phase I static tests include both one and two engine comparisons on the small and large radius flaps. Phase II static results are all based on the J/H flap and two engines operative, with the exception of a limited number of engine out checks.

The static turning angle was determined from the vector resolution of lift and drag forces on the model. The efficiency was also based on this assessment along with the calibrated input forces, flaps up.

Wind-On Tests

The Phase I wind-on investigations included the following items:

Item		Runs			
		Small Radius Jacobs/Hurkamp Flap	Large Radius Coanda Flap	<u>Total</u>	
Calibration		19	2	21	
USB Nacelle Integration		38	20	58	
Base Data					
All Engines	60 ⁰ Flaps	18		18	
	44 ⁰ Flaps		16	16	
	22 ⁰ Flaps	18		18	
Engine Out	60 ⁰ Flaps	12		12	
	22 ⁰ Flaps	5		5	
Control Flap Utilization		2		2	
Horizontal Tail Effectiveness		8	_	_4_	
		120	38	158	

The Phase 11 test included the following items:

Item	Runs			
	60 ⁰ Flaps	30° Flaps	22 ⁰ Flaps	Total
Calibration	28	2	2	32
Base Data				
All Engines	16	12	16	44
Engine Out	17	8	12	37
Control Flap Utilization	30	15		45
Horizontal Tail Effectiveness	9	2	8	19
Spoiler Effectiveness	15	7	3	25
USB Nacelle Deflector Study	25			25
USB/IBF PR Effects	15			15
	155	46	41	242

The wind-tunnel test results, as six-component balance data, were reduced on-line during the test and off-line after the test using the Control Data Corporation 1700 computer. Normal wind tunnel corrections accounting for balance interactions, weight tares, trapeze tares, wind tunnel wall effects, and freestream flow angularities were applied to the data. Wing lift data required for wall-effects corrections were obtained from appropriate tail-off configurations run during the test. Corrections for support system tare and interference were not made.

RESULTS

Static Tests

The static turning efficiencies (η_{f}) and static turning angles (δ_{j}) for all principal configurations in Phase I and II test programs are presented in table V. Phase I results are given for 60 degree J/H flaps with a variety of nacelle exit configurations (slot, E^3 , $U_{0'}^4, U_{10}^4$). The 22 degree J/H flap was checked only with the U_{0}^4 exit deflector. The 58 and 44 degree Coanda flaps were investigated with the slot, U_{0}^4 and U_{10}^4 nacelle exits. The U_{0}^4 deflector on the nacelle at 35 percent chord was selected for the Phase I base runs. Phase II static results are given for 60, 30 and 22 degree J/H flaps. The 60 degree flap was checked with $U_{0'}^4, U_{10}^4$ and U_{20}^4 nacelle exit deflectors and the U_{10}^4 was selected for use on the 30 and 22 degree flaps. The U_{10}^4 deflector set on the nacelle at 35 percent chord was selected for the main body of Phase II wind-on tests. The 60 degree J/H flap had an upper surface angle of 73.25 degrees and turned the jet 67.4 degrees under these conditions. The 30 degree J/H flap with an upper surface of 42.83 degrees turned the flow 38.4 degrees, and the 22 degree J/H flap with a 34.27 degree upper surface turned the flow 30.4 degrees.

Wind-On Tests

The basic stability axis results for the Phase I and II tests are presented in this section. C_L , C_D and C_m coefficient data are plotted for pitch runs and C_R , C_n and C_y data are plotted for the yaw runs. These results from the Phase I and II test programs are presented in the following figures:

<u>Phase I J/H Flap</u>	Figure
USB Nacelle Integration	8, 9
Base Data	10-17
Base Data Engine Out	18-22
Control Flap Utilization	23
Horizontal Stabilizer Effectiveness	24, 25

Wind-On Tests (Continued)

Phase I Coanda Flap	
USB Nacelle Integration	26
Base Data	27-30
Phase II J/H Flap	
Base Data	31-42
Base Data Engine Out	43-62
Control Flap Utilization	63-78
Horizontal Stabilizer Effectiveness	79-83
Spoiler Effectiveness	84-91
USB Nacelle Deflector Study	92-97
USB/IBF PR Effects	98-102

These results were secured with detailed attention given to the setting of the model geometry and blowing levels for each symmetric and asymmetric configuration. However, in selected cases it was not possible to "zero" all lateral-directional forces and moments during symmetric configurational runs. Under these conditions the side force and yawing moment were zeroed with some attendant rolling moment. Efforts to isolate the cause of this asymmetry were unsuccessful.

DISCUSSION

This section presents selected effects data based on the Phase I and II general results already given.

Phase I USB Nacelle Integration (J/H and Coanda Flaps)

Figure 103 shows the static turning angle and efficiency for AR 4.0 slot, U_0^4 , and U_{10}^4 deflector nacelle exits as a function of the nominal chordwise nacelle position on the wing with 60 degree J/H flaps. As the slot nozzle nacelle is moved forward on the wing the jet angle increases and the efficiency decreases. Installation of the ${\sf U}_{10}^4$ deflector reduces this effect as the jet angle is constant at approximately 60 degrees with 96 percent efficiency. Figure 104 presents the same type results for 58 degree Coanda flaps. The installation of the deflectors improves the static turning and efficiency of the basic slot nozzle. The deflector unit spreads and thins the jet efflux to aid in turning by reducing the jet height at the flap knee. The increase in efficiency is considered to be the result of flow changes from the nacelle in the static flaps-up calibration configuration and the flaps down static efficiency evaluation. Flaps-up calibration of the nacelles with deflectors results in considerable spanwise flow out of the open ends of the deflectors. Calibration thrust is based on the vector sum of only the normal and axial thrust components. When the flaps are deflected down the spanwise flow components from the nacelle tend to be drawn to the negative pressure region directly behind the nacelle and are reclaimed in the normal-axial plane. Figures 105 and 106 present wind-on results for the J/H and Coanda flaps deflected 60 and 44 degrees, respectively. The exit tailoring devices utilized statically were also used in wind-on runs. The static tendency of these devices to increase jet angle results in higher lift coefficients in the low alpha range and at stall. The J/H flap maximum lift increases from about 5.0 to 6.2 in going from the slot nozzle to U_{10}^4 deflector.

Phase I Base Data (J/H and Coanda Flaps)

The J/H flap in Phase I tests was investigated with 60 and 22 degree deflections. The Coanda flap was checked at a 44 degree deflection. Figure 107 illustrates the development of lift at zero alpha for these flaps as a function of thrust coefficient. At a thrust

coefficient of 1.8 the 60 degree J/H flap C_L is 4.4 and the 22 degree C_L is 2.4. Articulation of the aft control flap on the basic 22 degree J/H flap causes $a \pm \Delta C_L$ variation of approximately 0.6. The Coanda flap performance is also included in this figure. The larger radius does not seem to offer any performance advantage as shown in figure 108. J/H and Coanda flap upper surface angles are plotted against C_L at a C_T of 1.8 and all fall on the same general trend line. Figures 109 and 110 present the drag and pitching moment results for the same flap configurations. In figure 111 the maximum lift of the Coanda flap is noted to have dropped to the J/H 22 degree flap level.

Phase I Base Data, Engine Out (J/H Flap)

Figure 112 illustrates the impact of selected type engine failures on lift development with the 60 degree J/H flap. The all-engines operating case is shown with circle symbols. The box symbols represent an engine failure with the remaining engine powering the IBF system symmetrically on both sides of the model. At a nominal C_T of 1.0 the zero-alpha lift is unchanged and the maximum lift is down approximately 0.5. Triangular symbols represent an engine failure in a cross ducted arrangement where the loss of an engine results also in the loss of the IBF system on the opposite side of the model. The lift loss with this system is higher as zero-alpha lift is down 0.4 and maximum lift is down 1.1 at a C_T of 1.0.

Phase I Control Flap Utilization (J/H Flap)

Figure 113 shows the influence of the aft control flap articulation on zero-alpha and maximum lift. This small device is powerful in altering lift (and drag) and controlling flight path.

Phase | Horizontal Stabilizer Effectiveness (J/H Flap)

Figures 114 and 115 present the tail on runs with 60 and 22 degree J/H flaps, respectively. For both flap deflections the C_m change is -0.08 per degree of tail incidence.

Phase II Base Data

The Phase II test program was given completely to the J/H flap system. Three flap deflections (60, 30 and 22 degrees) are presented in figure 116. Zero-alpha and

maximum lift is given as a function of nominal thrust coefficient. At a thrust coefficient of 2.0 the lift coefficient at zero-alpha is 6.2 and the maximum lift is 7.9 with 60 degree flaps. The zero-alpha lift of 6.2 compares with 5.0 from Phase I (figure 105). This increase is attributed to reduced wing sweep (30 to 15 degrees) and reduced jet shear interference between USB and IBF jet efflux, increased aspect ratio (6.5 to 7.73), and increased body lift carryover.

Phase II Base Data, Engine Out

Figure 117 shows the result of an engine-out condition with cross ducting from left nacelle to right IBF. At a nominal thrust coefficient of 1.5 the 60 degree flap zeroalpha lift is 4.1, 30 degree flap lift is 3.3 and 22 degree flap lift is 2.5. In figure 118, a variety of engine out conditions is presented with 60 degree flaps. Those failures where the knee BLC is retained on both left and right wings are noted to have less lift loss than the failure case with knee BLC out. Trailing edge blowing is noted to have a secondary effect. Circle symbols present the case with right nacelle and left IBF system operative. The zero-alpha lift of 3.9 at a C_T of 1.0 has a rolling moment coefficient of -0.04. Box symbols represent the case of an engine out and all IBF systems operative. The lift in this case is up to 4.5 but the rolling moment is -0.22.

Phase II Control Flap Utilization

The aft vane of the trailing edge flap system is capable of being articulated to a maximum of 30 degrees, up (-) or down (+). The ability of the flap system to statically turn the jet efflux was investigated on 60 degree flap with +15, -15, +30 and -30 degree control flap articulation. The 30 degree flap was checked with +15 and -15 degree control flap deflections. Figure 119 presents the variation of jet angle and turning efficiency plotted against the flap upper surface angle. The basic 60 degree flap with upper surface angle of 73.25 degrees turns the flow 67.4 degrees. A +30 degree control flap deflection brings the upper surface angle to 103.25 with resulting jet angle of 84.5 degrees. The variation of jet angle with flap upper surface angle is approximately linear. The 30 degree flap with +15 control flap articulation closely follows the trend line for main flap deflections of 22, 30 and 60 degrees. This indicates that the control flap is as effective as the main flap in flow vectoring in the low flap deflection range. The static jet angle variation produces a wind-on lift variation presented in figure 120 for 60 degree flaps. At a nominal thrust coefficient of 2.0 the zero-alpha lift coefficient varies from 2.9 to 6.85. Figures 121 and 122 show the drag and pitching moment coefficient for the same flap variations. Maximum lift varies from 5.9 to 8.05 under the same conditions as shown in figure 123. Maximum lift development on the 60 degree flap with positive control flap deflection is noted to be limited to about 8.0. The high static jet angles (67.4 to 84.5 degrees) with the additional stall pitch angle pointed to a possible problem. The tunnel test section floor was tufted and the jet was found to be striking the floor under the model with some flow reversal, wind on.

The usefulness of the control flap as a flight path control device is pointed out in figures 124 and 125 as the lift and drag increments for control flap articulation on a basic 60 degree flap are shown. At a nominal thrust coefficient of 2.0 a symmetric +15 degree articulation produces a ΔC_L of 0.45 and ΔC_D of 0.62. The 30 degree flap results presented in figures 126 and 127 indicate a ΔC_L of 1.0 and ΔC_D of 0.45 under the same thrust and articulation conditions. In each of these cases thrust is supplied to the USB nacelles and IBF knee and trailing edge. The impact of variations in thrust input to these points is illustrated in figure 128 as the thrust to the trailing edge is reduced and then eliminated. Next, the knee blowing is eliminated and in this case the ability to vary lift by control flap articulation is still present. This would tend to indicate the flow is being turned effectively on the main flap before it reaches the trailing edge control flap.

Asymmetric deflection of the control flap as a lateral control device indicates a significant cross coupling in yaw and side force. Figure 129 shows the influence of a ± 15 and ± 30 degree control flap articulation on roll, yaw and side force coefficient. At a C_L of 5.7 the C_R is 0.1, C_n is -0.23 and C_y is 0.28 for a ± 30 left and ± 30 right control flap deflection on 60 degree flaps.

Phase II Horizontal Stabilizer Effectiveness

Tail-on runs were made with 60, 30 and 22 degree flaps. In each case the horizontal tail incidence was varied from ~5 (leading edge down) to +10 degrees. The zero-alpha

variation of C_m with incidence is -0.08 per degree on 60 degree flaps as shown in figure 130.

Phase 11 Spoiler Effectiveness

Ten-percent chord spoilers which spanned the trailing edge flaps were investigated with 10, 20 and 30 degree deflections. The spoiler hinge line was 0.10c forward of the flap knee BLC slot and this BLC slot remained unchanged with spoiler deflection. Figure 131 shows the effect of symmetric spoiler deployment with 60 degree J/H flaps. At a nominal thrust coefficient of 2.0 the zero-alpha lift coefficient is 6.2. The 10 degree spoiler reduces the lift to 3.5, 20 degree spoiler lift is 2.5 and 30 degree spoiler lift is 1.9. This solid spoiler spanning the complete trailing edge flap is a very powerful device. Spoiler deployment at other flap deflection produces the results given in figure 132. The spoiler's deflection largely controls the lift level, and for all flap deflections tested the 30 degree spoiler lift is constant. Part span solid spoilers were also investigated to reduce this drastic effect. Inboard half and quarter flap span spoilers were checked along with outboard half span units. Jwenty-degree spoiler results are shown in figure 133 at a nominal thrust coefficient of 2.0 with 60 degree J/H flaps. Starting without spoilers the zero-alpha lift is 6.2, outboard half span spoiler lift is 5.6, inboard quarter span spoiler lift is 4.2, inboard half span lift is 3.0 and full span spoiler lift is 2.5. Part span spoilers offer considerable variation in effectiveness. Figure 133 also shows the impact of cutting the spoilers to 50 percent porosity by spacing AR 1.0 tabs across the span. Porosity greatly reduces the spoiler effectiveness, and in conjunction with spanwise positioning the spoiler effectiveness can be set to a desired level.

These spoilers can also be deflected on one wing as a lateral control device. Figure 134 presents the resulting rolling moment change as the right spoiler is deflected 20 degrees. Outboard half span (#2), inboard half span (#4) and full right side (#5) spoilers are included. Asymmetric control flap results of ± 15 degree (#1) and ± 30 degree (#3) are also included for comparison.

Phase II USB Nacelle Deflector Study

A series of nacelle exit deflectors was attached to the basic aspect ratio 4.0 exit. The U^4 configuration was deflected down from the initial 20 degree closure angle by 0 (U_0^4),
10 (U_{10}^4) and 20 (U_{20}^4) degrees. The aspect ratio of these units was 4.9, 5.9 and 11.4 respectively. The nozzle exit height to flap knee radius ratio was 0.64 (U_0^4) , 0.53 (U_{10}^4) and 0.44 (U_{20}^4) . The U_{10}^5 deflector was formed from the U_{10}^4 by enclosing the deflector sides. The U_0^4 maximum lift was 7.2 as shown in figure 135. This increases to 7.9 and then 8.1 for U_{10}^4 and U_{20}^4 deflectors. The U_{10}^4 value of 7.9 is reduced to 6.7 when the deflector sides are closed to form the U_{10}^5 unit. The edge tailoring of exhaust deflectors is thus shown to be important in aerodynamic performance optimization. The U_{10}^4 was selected to further investigate the influence of nacelle chordwise position on the wing. Nominal 20, 35 and 50 percent chord nacelle positions were investigated. Figures 136 and 137 show the influence of nacelle position, and at a thrust coefficient of 2.0 maximum lift varies from 7.7 to 8.3 as the nacelle is moved forward on the wing. This forward movement allows increased spreading of the jet efflux over a greater portion of the flap span.

Figures 138 and 139 compre the U_{10}^4 and U_{10}^5 deflectors. Figure 138 presents static results and 139 presents wind-on results. Figure 138 indicates the U_{10}^5 deflector static jet angle was influenced by pressure ratio variations while the U_{10}^4 was not. The loss in jet angle with increasing PR in figure 138 is also reflected in a slight zero-alpha lift loss from 3.6 to 3.4 as the PR increases from 1.23 to 1.50. Figure 140 shows a lift comparison of the U_{10}^4 and U_{10}^5 units as a function of thrust coefficient. At a thrust coefficient of 1.0 the zero-alpha and maximum lift of the U_{10}^4 is 0.8 higher than the U_{10}^5 .

Phase II USB/IBF Pressure Ratio Effects

A more detailed study of pressure ratio effects was made with the U_{10}^4 deflector and selected blowing from the IBF knee and trailing edge. Figure 141 presents lift results with selected blowing from the nacelles; nacelles and knee; nacelles and trailing edge; and nacelles, knee and trailing edge. In the PR range from 1.2 to 1.6 little effect is recorded. The variation in lift was principally a function of blowing combinations and figure 142 shows the zero-alpha lift variation for selected blowing. The nacelle-alone lift was approximately 5.2, and the addition of trailing edge blowing increases lift to 5.6. The importance of knee blowing is emphasized as nacelle and knee blowing lift increases to 6.2 and the addition of trailing edge blowing to this configuration at a

1.5 PR shows little lift increase. Another important factor investigated in this section was the variation in relative USB and IBF pressure ratios. Selected nacelle-knee and nacelle-knee-trailing edge cases are shown in figure 143. A 20 percent reduction in knee PR below the USB nacelle PR level results in a zero-alpha lift reduction from 6.1 to 5.4.

CONCLUSIONS

The following conclusions are drawn from the Phase I and II small scale wind tunnel tests:

- 1. Phase I and II static tests indicate the hybrid powered lift concept offers high turning efficiency with minimum jet turning lag (difference between flap upper surface angle and static jet angle).
- 2. The small radius Jacobs/Hurkamp flap with knee BLC was found to work as well aerodynamically as the larger continuous radius Coanda flap without knee BLC.
- 3. The Phase I low wing performance level was not as high as the Phase II high wing. Phase II performance increases are attributed to increased aspect ratio, reduced sweep and resulting reduced shear between the USB and IBF jet efflux, and increased body lift carryover.
- Nacelle exit tailoring is important in aerodynamic performance optimization. Nacelle exit deflectors with open sides (U⁴) were found to be better than those with closed sides (U⁵).
- 5. Nacelle movement forward on the wing tends to give small increases in aerodynamic efficiency which must be traded against structural efficiency.
- 6. Nacelle pressure ratio effects were found to be minimum in the 1.2 to 1.6 range when the nacelle was fitted with an exit deflector.
- Nacelle and IBF pressure ratio differentials were found to be detrimental when the IBF knee PR dropped below the nacelle value.
- 8. Retention of the BLC at the flap knee was found to be the key in retaining high aerodynamic efficiency by attaching flow on the outboard flap span not influenced by the USB nacelles. Trailing edge blowing from the IBF system was found to have a secondary effect.

- 9. The hybrid powered high lift concept offers powerful flight path control effectiveness by the use of an aft control flap mounted at the main flap trailing edge.
- 10. The hybrid concept is very sensitive to spoiler deployment in the USB input regions on the wing. Spoiler position and porosity were found to be powerful in controlling effectiveness.

Figure 75. -

 Effect of Angle-of-Attack on Lateral-Directional Characteristics of the High Wing Model with the Left Engine and the Right BLC Systems Inoperative, 60° J/H Flap with +15° Left and -15° Right Aft Flap Deflection, 10° Open Deflector, Tail Off

Figure 76. -

Longitudinal Characteristics of the High Wing
Model with the Left Engine and the Right
BLC Systems Inoperative, 30° J/H Flap with
+15° Left and -15° Right Aft Flap Deflection,
10° Open Deflector, Tail Off

Figure 77. – Effect of Angle-of-Attack on Lateral-Directional Characteristics of the High Wing Model with the Left Engine and the Right BLC Systems Inoperative, 30° J/H Flap with +15° Left and -15° Right Aft Flap Deflection, 10° Open Deflector, Tail Off

Figure 78 – Longitudinal Characteristics of the High Wing Model with Selected Blowing, 60° J/H Flap 0°, +15° and -15° Symmetric Aft Flap Deflection, 10° Open Deflector, Tail Off

Figure 79. – Longitudinal Characteristics of the High Wing Model, ó0°/0° J/H Flap, -5° Horizontal Stabilizer Incidence, 10° Open Deflector

Figure 80. – Longitudinal Characteristics of the High Wing Model, 60°/0° J/H Flap, +5° and +10° Horizontal Stabilizer Incidence, 10° Open Deflector

Figure 81. – Longitudinal Characteristics of the High Wing Model, 30°/0° J/H Flap, -5°, 0°, and +10° Horizontal Stabilizer Incidence, 10° Open Deflector

Figure 82. – Longitudinal Characteristics of the High Wing Model, 22°/0° J/H Flap, ~5° Horizontal Stabilizer Incidence, 10° Open Deflector

Figure 83. – Longitudinal Characteristics of the High Wing Model, 22°/0° J/H Flap, +10° Horizontal Stabilizer Incidence, 10° Open Deflector

Figure 84. – Longitudinal Characteristics of the High Wing Model, 60°/0° J/H Flap, 10° Full Flap Span Solid Spoiler, 10° Open Deflector, Tail Off

Figure 85. – Longitudinal Characteristics of the High Wing Model, 60°/0° J/H Flap, Various Spoilers, 10° Open Deflector, Tail Off

Figure 86. – Longitudinal Characteristics of the High Wing Model, 60°/0° J/H Flap, Part Span Symmetric and Asymmetric 20° Spoiler Comparison, 10° Open Reflector, Tail Off

Figure 87. – Effect of Angle-of-Attack on Lateral-Directional Characteristics of the High Wing Model, 60°/0° J/H Flap, Part Span Asymmetric 20° Spoiler Comparison, 10° Open Deflector, Tail Off

Figure 88. – Longitudinal Characteristics of the High Wing Model, 60°/0° J/H Flap, Part Span 20° Porous Spoilers, 10° Open Deflector, Tail Off

Figure 89. – Longitudinal Characteristics of the High Wing Model, 30[°]/0[°] J/H Flap, Full Span 10[°] Solid Spoilers 10[°] Open Deflector, Tail Off

Figure 90. – Longitudinal Characteristics of the High Wing Model, 30°/0° J/H Flap, Symmetric Solid Full and Part Span 20° Spoilers, 10° Open Deflector, Tail Off

Figure 91- – Longitudinal Characteristics of the High Wing Model, 30°/0° J/H Flap, Symmetric Solid Spoilers, 10° Open Deflector, Tail Off

Figure 92. – Longitudinal Characteristics of the High Wing Model, 60°/0° J/H Flap, Variations in Nacelle Open Deflectors and Chordwise Exit Locations, Tail Off

Figure 93. – Longitudinal Characteristics of the High Wing Model, 60°/0° J/H Flap, 10° Open Deflector, Nozzle Exit at 20% Chord, Tail Off

Figure 94. – Longitudinal Characteristics of the High Wing Model, 60°/0° J/H Flap, 10° Open Deflector, Nozzle Exit at 50% Chord, Tail Off
