# FLUTTER TESTS (IS4) OF THE 0.0125-SCALE SHUTTLE REFLECTION PLANE MODEL 30-OTS IN THE LANGLEY RESEARCH CENTER 26-INCH TRANSONIC BLOWDOWN TUNNEL TEST NO. 547 By Michael A. Kotch, Rockwell International Space Division

#### ABSTRACT

A series of slab wing flutter models with rigid Orbiter fuselage, external tank, and SRB models of the Space Shuttle were tested, in a reflection plane arrangement, in the NASA Langley Research Center's 26-inch Transonic Blowdown Tunnel. Model flutter boundaries were obtained for both a wingalone configuration and a wing-with-Orbiter, tank and SRB configuration. Additional test points were taken of the wing-with-Orbiter configuration, as a correlation with the wing-alone condition. This report provides a description of the wind tunnel models and test procedures utilized in the experiment.

#### INTRODUCTION

This report describes the procedures and results of Test IS4, conducted in the NASA Langley Research Center (LaRC) 26-inch Transonic Blowdown Tunnel (TBT). The 30-OTS model consisted of a slab wing as a flutter specimen and rigid fuselage, tank and SRB structures, to simulate vehicle aerodynamics.

Purpose of this test was to isolate the effects of interfering aerodynamics, generated by the Orbiter, tank, and SRB, on the wing flutter boundary. To fulfill this objective, one boundary was determined for the wing alone (mounted on a splitter plate) while another boundary was obtained for the wing with models of the half-Orbiter, half-tank, and SRB, all mounted on a reflection plane (wing-OTS configuration). Additionally, two runs (37 and 38) were made with the wing and half-Orbiter on a reflection plane (wing-0 configuration). These runs indicated the validity of the wing-alone configuration in simulating basic wing aerodynamics.

Preliminary flutter boundaries (M vs. q) are presented for the wingalone and wing-OTS configurations. These boundaries include flutter points in the subsonic and transonic flight regions. Also included in this report are descriptions of the models and their properties. Presentations of the tunnel test conditions and run schedules are given in Tables I & II, respectively.

All material is unclassified.

#### REMARKS

All the test objectives of Test IS4 were accomplished during the period from 24 to 28 September 1973 in 57.5 chargeable hours including 7.5 hours for model installation.

The initial runs indicated that flutter points could not be obtained within tunnel operating limits with the original wings (#1-7) as fabricated for the test. Consequently, a more flexible wing (#1M), which was constructed for NASA and designed to flutter at lower dynamic pressures, was used for Runs 3-12. Steady state flutter points were obtained with this wing configuration over a narrow range of Mach numbers in the low transonic region. This wing was then modified to obtain an even lower stiffness level (1M\*, 2M\*) by milling slots in the wing root tab (Figure 2). More definite flutter boundaries were established with this wing for all scheduled model configurations extending from the high subsonic to high transonic regions during Runs 13-38. Plots of these data are shown in Figures 9 and 10.

No frequency data were obtained during Run 1 due to wind damage of instrumentation wires and Run 26 due to off-scale model signals. Wing 1M\* was damaged during Run 28 after being subjected to several seconds of steady state flutter and was replaced with wing 2M\* for subsequent runs in the IS4 test.

Divergent flutter conditions were not encountered during the IS4 phase of testing. Normally, as dynamic pressure was increased, the dynamic response would gradually progress from random excitation to intermittent flutter to steady state flutter. As a result, it was impossible to indicate exactly (in terms of M and q) where flutter was initiated. So, instead of a

sharp flutter boundary, only a flutter zone could be defined.

The more flexible 1M-8M wings, as modified on-site, which were used for the majority of the IS4 test and all of the subsequent NASA/LaRC phases of the program, were designed and fabricated by GAC as part of a current NASA shuttle development flutter program with GAC. The NASA testing phase was a logical extension of the Rockwell test since it incorporated common model components and mounting fixtures. Therefore, it was run immediately following completion of Test IS4 using consecutive run numbers and the same facility test number. The plotted data (Figures 11-14) and tabulated data have been included with the IS4 data, but the test objectives and descriptions have been presented in Appendix B.

#### CONFIGURATIONS INVESTIGATED

The 30-OTS model was a 0.0125-scale reflection plane model of the Shuttle system, including the Orbiter, ET and SRB. To isolate the interfering aerodynamic effects of the Orbiter fuselage, ET and SRB on the flutter behavior of the Orbiter wing, the model was tested in three configurations: wing alone, wing-with-Orbiter, and wing-with-Orbiter, ET, and SRB.

For the wing-alone configuration, the wing was supported at the root by a splitter plate which isolated the wing from the boundary layer effects of the reflection plane and the test section wall. The splitter plate also maintained the wing in the same test section position it had occupied in the other two configurations. In this way, any effects of tunnel flow field variation with test section position were eliminated.

For the wing-with-Orbiter configuration, the splitter plate was removed and the wing attached to a half-Orbiter mounted on the reflection plane.

The wing-with-Orbiter, ET, and SRB (-OTS) configuration was similar to the wing-with-Orbiter (-0) configuration, except a half-tank was mounted on the reflection plane and a SRB was rigidly clamped to the half-tank. The attachment truss between the Orbiter, tank, and SRB was provided for this configuration; however, the truss only provided aerodynamic simulation, and did not physically connect the tank to the Orbiter or SRB.

The wing stiffness distribution was approximated by properly located cutouts in a tapering thickness wing base plate. Aerodynamic contour of the wing was achieved by bonding balsa wood to the base plate and sealing the

wood with a suitable sealer to provide surface smoothness. To minimize the stiffness contribution of the balsa, the wood grain was oriented normal to the wing reference plane. Figure 1 illustrates three steps in wing construction.

A set of seven wings was prepared at one stiffness level for the SD tests; another set of eight wings was prepared for NASA-LaRC at a lower stiffness level and made available for Test IS4. This latter set was further reduced in stiffness by milling slots in the wing base plate as detailed by Figure 2.

Only the wing stiffness was simulated for this test; all other structures (Orbiter, ET, and SRB) were rigid bodies mounted, without flexibility, to the reflection plane. Figure 3 illustrates the wing and bodies mounted in this manner.

The wing leading and trailing edges were painted to provide distinctive color contrast for the test movie film. The Orbiter, ET, and SRB were also outlined with a contrasting color. A vertical reference line was provided on the splitter plate and reflection plane at the intersection of the wing trailing edge. Horizontal reference lines were provided on the plate and reflection plane at, and  $\pm 1$  inch from, the wing reference plane.

Nomenclature for Model 30-OTS is as follows:

BT/	Body
C7	Canopy
м4	OMS pod
W115	Wing

S8 Solid Rocket Booster

### T10 External Tank

Table III tabulates dimensional data for this model, based on the VL-70-900139 configuration 3 Orbiter. The model wing lines exclude camber, twist, and dihedral. Hence, thickness distribution from  $Y_0 = 108$  to  $Y_0$ = 199.045 has been reduced to ensure continuity at the wing-body interface.

The half-Orbiter and the half-external tank are left-hand models.

Model drawings used for this test are as follows:

Number	Title
SS-S-00275	General Arrangement
SS-S-00276	Wing
SS-S-00277	Splitter Plate
SS-S-00278	Fuselage
SS-S-00279	Tank & SRB
SS-S≏00280	Struts, Fwd-Aft
SS-S-00281	General Assy, Wing/Body
SS-S-00282	General Assy-Wing Alone
SS-S-00326	Basic Wall Mount
SS-S-00328	Mounting Plate Layout

Model drawings are included in Reference 1, and are available from GAC. Reduced drawings of the general assemblies (-281 and -282) are included in this report as Figures 4 and 5.

#### INSTRUMENTATION

Instrumentation on the model consisted of two strain gage circuits of four gages each. The strain gages were located near the wing root, and were used to measure wing bending and torsion. Figure 6 illustrates the model instrumentation locations.

Tunnel parameters were measured with two static pressure transducers (one spare), one total pressure transducer, and two total temperature thermocouples (one spare).

Model dynamic response was recorded by a 1000 frames/sec movie camera viewing the model from the side.

Model and tunnel parameter instrumentation were input through amplifiers and signal conditioners and recorded on a high-speed oscillograph. A static pressure and a total pressure reference trace were also recorded on the oscillograph to permit absolute determination of tunnel pressures. A 60 Hz signal was recorded as a frequency reference, and a "camera on" reference was provided, yielding nine channels of recorded data and references.

LaRC provided additional instrumentation for pre and post-run frequency checks. This instrumentation consisted of a dual-beam oscilloscope, a variable-frequency oscillator, an electromechanical and a suitable amplifier to drive the shaker.

Figure 7 illustrates, in block diagram form, the arrangement of the test instrumentation.

### FACILITY DESCRIPTION

Air was the test medium. The tunnel exhausts into the atmosphere. It is operated manually with independent control of Mach and Reynolds numbers. The test section is octagonally slotted and measures 26 inches between flats.

Operating conditions of the tunnel are as follows:

Mach number	0.6 to 1.45
Stagnation pressure	20 to 75 psia
Stagnation temperature	510 to 550° <sub>R</sub>
Reynolds number per foot	$2.0 \times 10^6$ to 27.0 x $10^6$
Run time (depending on Mach number and stagnation pressure)	20 to 50 sec.

Figure 8 shows typical operating characteristics of the LRC 26-inch TBT.

#### TEST PROCEDURES

The model reflection plane was mounted on the starboard wall of the test section, looking upstream. The reflection plane served as the base for the three model configurations:

- Wing-Alone. The model splitter plate was attached with spacers and bolts to the reflection plane, and the wing root was bolted to the splitter plate.
- 2. Wing-with-Orbiter. The wing and half-Orbiter were attached to the reflection plane.
- 3. Wing-with-Orbiter, ET and SRB. The wing, half-Orbiter, and halftank were attached to the reflection plane. The one SRB was bolted to the half-tank.

Model instrumentation wiring was routed from the wing through the model splitter plate and/or reflection plane to terminal strips in the plenum chamber surrounding the test section.

The model was installed at a nominal 0° angle of attack to minimize static loads on the wing. This was verified by monitoring the mean deflection of the wing bending and torsion oscillograph traces during the initial runs.

The general test procedure for each run was as follows:

- 1. Install and visually inspect the model in the tunnel.
- 2. Perform sign checks of model instrumentation.
- 3. Perform the pre-run frequency and damping checks.
- 4. Make preparations to achieve the desired tunnel operating conditions (Mach number and total pressure).

- 5. Perform instrumentation and system checks, including pre-run pressure transducer and thermocouple calibrations.
- 6. Begin run, starting camera at preselected total pressure.
- Shutdown the tunnel when the operating limit was reached or when flutter occurred. Take post-run calibrations.
- Perform the post-run model inspection and frequency and damping checks to determine if the model was damaged.

During a series of runs, where the model was not damaged in the prior run, and was to be run again, only steps 4 thru 8 were followed.

The sign checks performed in step 2 above were to assure uniform trace direction on the oscillograph records for all the models. The sign convention utilized was:

- 1. Positive bending Tip up
- 2. Positive torsion Leading edge up

The positive direction on the oscillograph traces was always to the right of the zero line, facing the recorder.

The technique utilized to obtain a particular flutter point depended on the region of interest and the known characteristics in the neighborhood of this region, but always followed one of two approaches. In the first approach, the downstream tunnel diffuser throat was set at a constant predetermined area to yield a constant nominal Mach number. Tunnel total pressure was then increased, and correspondingly the dynamic pressure, until the tunnel operating limit or flutter was attained. On occasion a second approach was utilized to minimize the potential for damaging the model.

This approach called for the increase of tunnel total pressure to a preselected constant, while at a predetermined initial diffuser throat valve setting. The valve setting was then either increased or decreased, altering Mach number and, to a lesser extent, dynamic pressure, until flutter was achieved, or the tunnel could no longer provide the desired total pressure. This latter approach provided more data points in the neighborhood of the flutter boundary, but used up a greater volume of stored air, and was not always capable of achieving the desired Mach number and dynamic pressure, due to the operating limitations of the tunnel.

All tunnel and model instrumentation data were recorded on an oscillograph, both during the runs and during pre and post-run frequency checks. In the latter case, model frequencies were read from the bending and torsion records.

The tunnel pressure and temperature required calibration signals since they were absolute measurements. Calibration readings were made immediately prior to and after each run. All pressure data were zeroed to atmospheric pressure;  $P_{atm}$  was obtained before each run from NASA-LaRC. Tunnel temperature zero was recorded on the oscillograph by switching the thermocouple switch to the "zero" position.

Normally only dynamic response was of interest for the model instrumentation. Hence no calibration or zero signals were required; however, during the initial runs a check was made to ensure that the wing static loads were not excessive. For this purpose a nominal bending moment and torque were applied to the wing. The deflection of the respective instrumentation signals on the oscillograph indicated load limits for the wing.

### DATA REDUCTION

Given  $P_o$  and  $P_s$  from the test data we have

$$M = \left[ \frac{2 \left[ \left(\frac{P_{o}}{P_{s}}\right)^{\frac{\gamma-1}{\gamma}} - 1 \right]}{\gamma - 1} \right]^{\frac{1}{2}} \text{ and } Q = \gamma/2 M^{2} P_{s}$$

M & Q were calculated for selected points on the oscillograph record of each run and were plotted on a tunnel typical operating characteristics chart (Figure 8) to determine the tunnel conditions for the next run.

M & Q for these points were also plotted as in Figures 9 and 10 to define the flutter boundary.

Additional parameters of interest were also calculated during posttest data reduction. Tunnel temperature,  $T_0$ , from the test data was in °F and was first converted to °R; then the following calculations were made:

$$V = AM$$

 $\mathbf{or}$  $V = \sqrt{\gamma RT} M$ 

. .

where 
$$T_s = \frac{T_o}{(1 + \gamma - 1 M^2)}$$

Also, RHO = 
$$2Q/V^2$$
  
and VKEAS =  $\left[\frac{288Q}{RHOSL}\right]^{1/2}$  (0.5921)  
Finally, RN =  $\frac{P_o}{\mu_o} \frac{M}{\sqrt{-\frac{\gamma}{(\gamma - 1)} C_v T_o}} \left[\frac{T_o}{T_s}\right]^{\frac{\gamma - 2}{2}} \left[\frac{T_s + 198.6}{T_o + 198.6}\right]$   
where  $\mu_o = 2.270 \left[\frac{T_o}{T_o + 198.6}\right] \times 10^{-8}$ 

For the above the following constants were used:

$$C_v = 4290 \text{ ft}^2/\text{sec}^2 \circ R$$
  
 $\gamma = 1.4$   
 $R = 1716 \text{ ft}^2/\text{sec}^2 \circ R$   
RHOSL = 0.0023769 slugs/ft<sup>3</sup>

The above procedures are taken from References 2 and 3.

.

# DISCUSSION OF RESULTS

Each model assembly underwent vibration tests at GAC before wind tunnel testing. These tests are used by GAC for the model flutter analysis that supports this test program (see Reference 4).

One model assembly of each stiffness level was subjected to a complete ground vibration survey (GVS). Subsequent models were checked for frequencies,  $f_i$ , and damping coefficients,  $g_i$ , and node line locations. GVS frequencies are summed in Table IV.

Pre and post-run frequency checks were made in the test section during the test. Since the wing root tab modification was made during the test, no GVS data was available for comparison after run 12. In this case, the initial frequencies obtained during the pre-run 13 frequency check were taken as target frequencies for subsequent runs. Pre and post-run frequencies are tabulated in Table V.

Tabulated data of tunnel conditions of points of interest in the test are presented in Appendix A. These points were utilized in defining preliminary flutter boundaries. Explanation of the tabulated data format is found in Table VI.

Preliminary model flutter points for the wing-alone and wing/OTS configurations are presented in Figures 9 and 10, respectively. Because these points must be corrected to reflect actual flight densities, of the actual shuttle trajectory, no conclusions can be presented other than, flutter points were obtained for subsonic and transonic flow conditions. (GAC will present a final model analysis with corrected test data comparisons). Due

to the rapid recovery of the flutter boundary in the supersonic region, it was not possible to obtain flutter information in this area within the tunnel operating limits.

As noted in the Remarks section, the model flutter behavior changed gradually, and not abruptly, over a range of dynamic pressure. The boundary is not a clearly defined line, but more like a zone. The boundary indicated in the figures is a qualitative description of the bounds where intermittent flutter became pronounced.

#### APPENDIX B

#### NASA TEST OF THE 30-OTS MODEL

#### B-1 Remarks

Following the Rockwell SD tests of the 30-OTS model, NASA-LaRC conducted a Space Shuttle Technology research test on the model from 1 to 5 October, 1973; 56 Runs were completed. This test was covered by the same facility test number - TBT547 - as SD test IS4. So, the run sequence for this test went from run 39 to run 94.

Purpose of the test was to examine the aerodynamic effects of a flexibly mounted SRB on the wing flutter boundary. Two SRB mount stiffness levels, which bracket SD design levels, were tested.

#### **B-2** Configurations Investigated

The model utilized for this test was the same as used for SD test IS4 except for the SRB mounting arrangement. The SD SRB was a simple body, geometrically scaled, and rigidly mounted to the external tank. The SRB used for the NASA test was additionally scaled to mass and inertia. The NASA SRB mount consisted of two flexures which duplicated scaled SRB pitch, vertical translation, and first-bending frequencies. In this way, unsteady aerodynamics of a flexible SRB could be simulated. It should be noted that there was no structural path between the wing and the SRB to simulate inertial coupling.

Two sets of flexures, simulating two different stiffness levels, were provided. These were identified as Case I and Case II, flexible and stiff respectively.

Model drawings for this test are identical to test IS4 drawings, with the following additions:

# Drawing NumberTitle518 MOD 1513Tank flexures, Assy and Details518 MOD 15140° + -3° Body, Wing, E Tank, & SRB

The above drawings are available from GAC.

#### **B-3** Instrumentation

Wing instrumentation and tunnel parameter instrumentation for this test were identical to test IS4. Additional instrumentation consisted of bending strain gage circuits on the SRB-ET flexures. As with the wing gages, the signals were conditioned and recorded on a high-speed oscillograph. SRB pitch and vertical translation could be ascertained by studying the relative amplitudes and phase difference between the oscillograph records of the fore and the aft ET-SRB flexures.

B-4 Test Procedures

Test procedure for this test was identical to the procedure of test IS4.

#### B-5 Results

Pre-and post-run frequency data for this test is included in Table V of this report. Tabulated data of selected points from Runs 39 through 94 (i.e. this test) are included with the test IS4 data in Appendix A.

Figures 11 through 14 illustrate the flutter points obtained during this test. Note that in Figure 11 data is included from test IS4 Runs
37 & 38.

A comparison of Figure 11, the test baseline, with Figures 13 and 14, which show the OTS Case I and Case II, configurations, respectively, indicates some alteration of the flutter boundary with SRB flexibility. However, the difference is not very great at any Mach number, and at no time is a severe wing/SRB aerodynamic coupling indicated.
