## Abstract

Let  $X, Y$  be two continuous random variables. Investigating the regression dependence of  $Y$  on  $X$ , respectively, of  $X$  on  $Y$ , we show that the two of them can have almost opposite behavior. Indeed, given any  $\varepsilon > 0$ , we construct a bivariate random vector  $(X, Y)$  such that the respective regression dependence measures  $r_{2|1}(X, Y), r_{1|2}(X, Y) \in [0, 1]$  introduced in Dette et al. (2013) satisfy  $r_{2|1}(X, Y) = 1$  as well as  $r_{1|2}(X, Y) < \varepsilon$ .

## 1 Introduction and results

Recently, Dette et al. (2013) presented a new approach to the problem of ordering and measuring regression dependence in the bivariate case. Let  $(X, Y)$

be a bivariate random vector. Since regression dependence is a directional relationship, it is first necessary to specify the direction of interest. Without loss of generality, consider the dependence of  $Y$  on  $X$ . The fundamental idea behind regression is predictability – the more predictable  $Y$  is from  $X$ , the more regression dependent they are. It is straightforward to single out the two extreme cases: independence and almost sure functional dependence, when there exists a Borel measurable function  $g$  such that  $Y = g(X)$  with probability one (Lancaster, 1963). In the former case,  $X$  provides no information about  $Y$ , whereas in the latter case there is perfect predictability of  $Y$  from  $X$ .

Apart from the two extreme cases, however, there exists a variety of intermediate ones with a certain degree of regression dependence. In order to measure the strength of dependence of  $Y$  on  $X$ , Dette et al. (2013) defined a nonparametric measure of regression dependence,  $r_{2|1}(X, Y) \in [0, 1]$ . Beside being monotone in a regression dependence order, the measure takes on its extreme values precisely at independence and almost sure functional dependence, respectively, i.e., we have

- (i)  $r_{2|1}(X, Y) = 1$  if and only if  $Y$  is a.s. a Borel function of  $X$ .
- (ii)  $r_{2|1}(X, Y) = 0$  if and only if  $X$  and  $Y$  are independent.

Analogously, one can define a measure  $r_{1|2}(X, Y) = r_{2|1}(Y, X)$  measuring the degree of dependence of  $X$  on  $Y$ .

We point out that it is important to have equivalences in both of the properties (i) and (ii), because only then the value  $r_{2|1}(X, Y)$  can serve as a genuine measure of how much  $Y$  is dependent on  $X$ . Indeed, if we only had  $r_{2|1}(X, Y) = 0$  if (but not only if)  $X$  and  $Y$  are independent, then an assertion like  $r_{2|1}(X, Y) < \varepsilon$  would not imply that  $Y$  is ‘almost independent’ from  $X$ .

The following is the main result of the present paper.

**Theorem 1.** *For any given  $\varepsilon > 0$ , there is a random vector  $(X, Y)$  such that*

the following assertions hold:

1.  $r_{2|1}(X, Y) = 1$ , i.e.,  $Y$  is a.s. a Borel function of  $X$ .
2.  $r_{1|2}(X, Y) < \varepsilon$ .

The paper is organized as follows. In Section 2 we give a quick review of the construction in Dette et al. (2013) of the nonparametric measure  $r_{2|1}$  of regression dependence. Section 3 then contains the proof of Theorem 1, and relates this result to other problems in the literature.

## 2 Preliminaries

In this section we recall the basic notion of copula and the definition of the nonparametric measure of regression dependence introduced in Dette et al. (2013). A (two-dimensional) copula is a function  $C : I^2 \rightarrow I$  with  $I := [0, 1]$ , satisfying the following conditions:

1.  $C(x, 0) = C(0, y) = 0$  for all  $x, y \in I$
2.  $C(x, 1) = x$  and  $C(1, y) = y$  for all  $x, y \in I$
3.  $C$  is 2-increasing, i.e.,  $C(x_2, y_2) - C(x_2, y_1) - C(x_1, y_2) + C(x_1, y_1) \geq 0$  for all rectangles  $[x_1, x_2] \times [y_1, y_2] \subset I^2$ .

These conditions imply further key properties. A copula is Lipschitz continuous and increasing in each argument; therefore, its partial derivatives exist a.e. on  $I^2$ . We refer the reader to Nelsen (2006) for more information about copulas.

Given two continuous random variables  $X$  and  $Y$  with corresponding copula  $C$ , the measure of regression dependence  $r_{2|1}(X, Y)$  introduced in Dette et al. (2013) is defined by

$$r_{2|1}(X, Y) = 6\|\partial_1 C\|_2^2 - 2 = 6 \int_{I^2} |\partial_1 C(x, y)|^2 d(x, y) - 2 \quad (1)$$

where  $\partial_1$  denotes the partial derivative with respect to the first variable and  $\|\cdot\|_2$  is the  $L^2$ -norm on  $I^2$ . The quantity  $r_{2|1}$  measures the degree of dependence of  $Y$  on  $X$ . It is a measure of regression dependence with respect to two natural regression dependence orders, also introduced in Dette et al. (2013).

Analogously, one can define a measure

$$r_{1|2}(X, Y) = 6\|\partial_2 C\|_2^2 - 2 = r_{2|1}(Y, X)$$

such that this quantity measures the degree of dependence of  $X$  on  $Y$ .

### 3 Two proofs of Theorem 1

In this section, we will construct two sequences  $(X_n, Y_n)$  of bivariate random vectors such that

$$r_{2|1}(X_n, Y_n) = 1 \text{ for all } n, \quad (2)$$

$$\lim_{n \rightarrow \infty} r_{1|2}(X_n, Y_n) = 0. \quad (3)$$

This proves Theorem 1. In fact, we will construct sequences of copulas  $C_n$  rather than the random variables themselves. This is sufficient because the measures  $r_{2|1}$  and  $r_{1|2}$  depend only on the corresponding copula. For the construction of these copulas, we use the so-called gluing method developed in Siburg and Stoimenov (2008a). For the convenience of the reader, we quickly recall its definition.

Given two copulas  $C_1, C_2$  and a parameter  $\theta \in (0, 1)$ , we define the function

$$(C_1 \circledast_{x=\theta} C_2)(x, y) = \begin{cases} \theta C_1\left(\frac{x}{\theta}, y\right) & \text{if } 0 \leq x \leq \theta \\ (1 - \theta)C_2\left(\frac{x - \theta}{1 - \theta}, y\right) + \theta y & \text{if } \theta \leq x \leq 1 \end{cases} \quad (4)$$

Thus,  $C_1 \circledast_{x=\theta} C_2$  corresponds to gluing the two copulas  $C_1$  and  $C_2$ : it equals  $C_1$ , rescaled and fit into the rectangle  $[0, \theta] \times I$ , and equals  $C_2 + \theta y$ , rescaled

Figure 1: The support of the singular copula  $C$  in Example 1

and fit into  $[\theta, 1] \times I$ . It is shown in Siburg and Stoimenov (2008a) that the gluing process yields a copula again, i.e.,  $C_1 \otimes_{x=\theta} C_2$  is a copula for any parameter  $\theta$ . For later purposes, we need also the gradient of the resulting copula which is given by

$$\begin{aligned} & \nabla(C_1 \otimes_{x=\theta} C_2)(x, y) \\ &= \begin{cases} \left( \frac{\partial C_1}{\partial x} \left( \frac{x}{\theta}, y \right), \theta \frac{\partial C_1}{\partial y} \left( \frac{x}{\theta}, y \right) \right) & \text{if } 0 \leq x \leq \theta \\ \left( \frac{\partial C_2}{\partial x} \left( \frac{x-\theta}{1-\theta}, y \right), (1-\theta) \frac{\partial C_2}{\partial y} \left( \frac{x-\theta}{1-\theta}, y \right) + \theta \right) & \text{if } \theta \leq x \leq 1 \end{cases} \quad (5) \end{aligned}$$

Let us first illustrate the gluing construction with a fundamental example. Recall that a copula  $C$  is called singular if its density  $\partial^2 C / \partial x \partial y$  vanishes almost everywhere in  $I^2$ . Moreover, the support of a copula  $C$  is defined as the complement of the union of all (relatively) open subsets of  $I^2$  whose measure, induced by  $C$ , is zero. We refer to Nelsen (2006) for more details.

*Example 1.* Let  $\theta \in (0, 1)$ , and suppose that the probability  $\theta$  is uniformly distributed along the line segment joining  $(0, 0)$  and  $(\theta, 1)$ , and the probability  $1 - \theta$  is uniformly distributed along the segment between  $(\theta, 1)$  and

(1,0). Consider the resulting singular copula  $C_\theta$  whose support consists of these two line segments; see Figure 1. It follows (see (Nelsen, 2006, Ex. 3.3)) that

$$C_\theta(x,y) = \begin{cases} x & \text{if } x \leq \theta y \\ \theta y & \text{if } \theta y < x < 1 - (1 - \theta)y \\ x + y - 1 & \text{if } 1 - (1 - \theta)y \leq x. \end{cases}$$

Note that  $C_\theta$  can be written as the gluing

$$C_\theta = C^+ \circledast_{x=\theta} C^-$$

where  $C^+(x,y) = \min(x,y)$  and  $C^-(x,y) = \max(x+y-1,0)$  are the upper and lower Fréchet-Hoeffding bound, respectively.

Since the support of  $C_\theta$  is a graph over the  $x$ -axis, this copula links random variables  $X$  and  $Y$  where  $Y$  is completely dependent on  $X$ . This follows from Dette et al. (2013, Prop. 1) and the fact that a function is Borel measurable if and only if its graph is Borel measurable and has probability one (Buckley, 1974). On the other hand,  $X$  is not completely dependent on  $Y$  because the support of  $C_\theta$  is not a graph over the  $y$ -axis.

This example will serve as a fundamental building block for our final construction of copulas  $C_n$  satisfying (2) and (3).

*First proof of Theorem 1.* We start with the copula  $C^+ \circledast_{x=\theta} C^-$  from Example 1 where, in order to simplify calculations, we set  $\theta = 1/2$ . Then we define  $C_n$  inductively by

$$\begin{aligned} C_1 &= C^+ \circledast_{x=1/2} C^- \\ C_{n+1} &= C_n \circledast_{x=1/2} C_n \end{aligned}$$

for  $n \geq 1$ . We claim that

$$\int_{I^2} |\partial_1 C_n(x,y)|^2 d(x,y) = \frac{1}{2} \tag{6}$$

Figure 2: The gradient of the copula  $C_3$  in the first proof of Theorem 1

for all  $n \geq 1$ , as well as

$$\int_{I^2} |\partial_2 C_n(x, y)|^2 d(x, y) \rightarrow \frac{1}{3} \quad (7)$$

as  $n \rightarrow \infty$ . These relations imply that

$$r_{2|1}(X, Y) = 6 \int_{I^2} |\partial_1 C_n(x, y)|^2 d(x, y) - 2 = 1$$

for all  $n$ , as well as

$$r_{1|2}(X, Y) = 6 \int_{I^2} |\partial_2 C_n(x, y)|^2 d(x, y) - 2 \rightarrow 0$$

as  $n \rightarrow \infty$ , which are precisely the assertions (2) and (3) that we wanted to prove.

For the proof of (6) and (7), we have to calculate the gradient  $\nabla C_n$ . Using (5) and the fact that  $1 - \theta = \theta = 1/2$ , we see that  $\partial C_n / \partial x = 1$  in the upper and  $\partial C_n / \partial x = 0$  in the lower triangles formed by the line segments of the support of  $C_n$ , and the second component  $\partial C_n / \partial y$  takes the values  $0, 1/2^n, 2/2^n, \dots, (2^n - 1)/2^n, 1$  respectively; see Figure 2 for the case  $n = 3$ .

Since the gradient of  $C_n$  is constant on each triangle, the integration reduces to multiplying the square of the respective constant with the area of

the corresponding triangle. Thus, considering the first component of the gradient, we obtain

$$\int_{I^2} |\partial_1 C_n(x, y)|^2 d(x, y) = \frac{1}{2}$$

for each  $n \geq 1$ , proving (6).

The integral for the second component amounts to

$$\int_{I^2} |\partial_2 C_n(x, y)|^2 d(x, y) = \left[ \sum_{i=1}^{2^n-1} \left( \frac{i}{2^n} \right)^2 \cdot \frac{1}{2^n} \right] + 1^2 \cdot \frac{1}{2^{n+1}}$$

where the last term stems from the triangle containing the vertex  $(1, 1)$  which is just half as big as the other ones. Using the formula

$$\sum_{i=1}^{k-1} i^2 = k^3/3 + \mathcal{O}(k^2)$$

we conclude that

$$\int_{I^2} |\partial_2 C_n(x, y)|^2 d(x, y) = \frac{1}{2^{n+1}} + \left( \frac{1}{2^n} \right)^3 \cdot \sum_{i=1}^{2^n-1} i^2 = \frac{1}{3} + \mathcal{O}\left( \frac{1}{2^n} \right)$$

as  $n \rightarrow \infty$ , proving also our claim (7).  $\square$

We conclude this section with a second proof of Theorem 1 where we use an even simpler building block than in the previous one.

*Second proof of Theorem 1.* Choosing  $C^+$  as a building block instead of  $C^+ \otimes_{x=1/2}$   $C^-$ , we consider the copulas

$$C_1 = C^+$$

$$C_{n+1} = C_n \otimes_{x=1/2} C_n$$

for  $n \geq 1$ . We claim that both (6) and (7) hold also for this choice of copula  $C_n$ .

Setting  $\theta = 1/2$  in (5), one sees that  $\partial_1 C_n$  takes the values 0 and 1, each in  $2^{n-1}$  triangles of area  $1/2^n$ ; compare Figure 3 indicating the gradient of

$$C_3 = (C^+ \otimes_{x=1/2} C^+) \otimes_{x=1/2} (C^+ \otimes_{x=1/2} C^+).$$

Figure 3: The gradient of the copula  $C_3$  in the second proof of Theorem 1

Therefore,

$$\int_{\mathcal{I}^2} |\partial_1 C_n(x, y)|^2 d(x, y) = \frac{1}{2}$$

for each  $n \geq 1$ , proving (6).

The second component  $\partial_2 C_n$  takes the values  $0, 1/2^{n-1}, 2/2^{n-1}, \dots, (2^{n-1} - 1)/2^{n-1}, 1$  respectively, so that we obtain

$$\begin{aligned} \int_{\mathcal{I}^2} |\partial_2 C_n(x, y)|^2 d(x, y) &= \left[ \sum_{i=1}^{2^{n-1}} \left( \frac{i}{2^n} \right)^2 \cdot \frac{1}{2^n} \right] + 1^2 \cdot \frac{1}{2^{n+1}} \\ &= \frac{1}{2^{n+1}} + \left( \frac{1}{2^n} \right)^3 \cdot \sum_{i=1}^{2^{n-1}} i^2 \\ &= \frac{1}{3} + \mathcal{O}\left(\frac{1}{2^n}\right) \end{aligned}$$

for  $n \rightarrow \infty$ , proving also (7).  $\square$

Finally, we would like to point out that these examples also provide a positive answer to a question stated in Siburg and Stoimenov (2008b). Namely, for both our examples above we have

$$\lim_{n \rightarrow \infty} \int_{\mathcal{I}^2} |\nabla C_n(x, y)|^2 d(x, y) = \frac{1}{2} + \frac{1}{3} = \frac{5}{6}, \quad (8)$$

which shows that the bound  $5/6$  given in Siburg and Stoimenov (2008b, Thm. 18(ii)) and Siburg and Stoimenov (2010, Thm. 4.3(ii)) is sharp.
