THE COLOURFUL SIMPLICIAL DEPTH CONJECTURE

PAULINE SARRABEZOLLES

Abstract. Given $d+1$ sets of points, or colours, $S_1, \ldots, S_{d+1}$ in $\mathbb{R}^d$, a colourful simplex is a set $T \subseteq \bigcup_{i=1}^{d+1} S_i$ such that $|T \cap S_i| \leq 1$, for all $i \in \{1, \ldots, d+1\}$. The colourful Carathéodory theorem states that, if $0$ is in the convex hull of each $S_i$, then there exists a colourful simplex $T$ containing $0$ in its convex hull. Deza, Huang, Stephen, and Terlaky (Colourful simplicial depth, Discrete Comput. Geom., 35, 597–604 (2006)) conjectured that, when $|S_i| = d + 1$ for all $i \in \{1, \ldots, d+1\}$, there are always at least $d^2 + 1$ colourful simplices containing $0$ in their convex hulls. We prove this conjecture via a combinatorial approach.

1. Introduction

A colourful point configuration is a collection of $d+1$ sets of points $S_1, \ldots, S_{d+1}$ in $\mathbb{R}^d$. A colourful simplex is a subset $T$ of $\bigcup_{i=1}^{d+1} S_i$ such that $|T \cap S_i| \leq 1$. The colourful Carathéodory theorem, proved by Bárány in 1982 [1], states that, given a colourful point configuration $S_1, \ldots, S_{d+1}$ in $\mathbb{R}^d$ such that $0 \in \bigcap_{i=1}^{d+1} \text{conv}(S_i)$, there exists a colourful simplex $T$ containing $0$ in its convex hull. In the same paper, Bárány uses this theorem combined with Tverberg’s theorem to give a bound on simplicial depth. His argument motivated the following question: how many colourful simplices, at least, contain $0$ in their convex hulls?

Let $\mu(d)$ denote the minimal number of colourful simplices containing $0$ in their convex hulls over all colourful point configurations $S_1, \ldots, S_{d+1}$ in $\mathbb{R}^d$ such that $0 \in \text{conv}(S_i)$ and $|S_i| = d + 1$ for $i = 1, \ldots, d+1$. The colourful Carathéodory theorem states that $\mu(d) \geq 1$. The quantity $\mu(d)$ has been investigated by Deza, Huang, Stephen, and Terlaky [3]. They proved that $2d \leq \mu(d) \leq d^2 + 1$ and conjectured that $\mu(d) = d^2 + 1$. Later Bárány and Matoušek [2] proved that $\mu(d) \geq \max\left(3d, \left\lceil \frac{d(d+1)}{5} \right\rceil \right)$ for $d \geq 3$, Stephen and Thomas [6] proved that $\mu(d) \geq \left\lceil \frac{(d+2)^2}{4} \right\rceil$, and Deza, Meunier, and Sarrabezolles [5] improved the bound to $\frac{1}{2}d^2 + \frac{7}{2}d - 8$ for $d \geq 4$. This latter result was obtained using a combinatorial generalization of the colourful point configurations suggested by Bárány and known as octahedral systems, see [4].

We use this combinatorial approach to prove the conjecture.

Theorem 1. The equality $\mu(d) = d^2 + 1$ holds for every integer $d \geq 1$.

The outline of the paper goes as follows. Section 2 is divided into two parts. First we define the octahedral systems and show their link with the colourful point configurations. Second, we introduce one of our main tools: the decomposition of an octahedral system over some elementary octahedral systems called umbrellas. Section 3 is devoted to the proof of Theorem 1.

Date: February 14, 2014.

Key words and phrases. Colourful Carathéodory Theorem, colourful simplicial depth, octahedral systems, $n$-partite $n$-uniform hypergraphs.
2. Preliminaries

2.1. Octahedral systems. Let \( V_1, \ldots, V_n \) be \( n \) pairwise disjoint finite sets, each of size at least 2. An octahedral system is a set \( \Omega \subseteq V_1 \times \cdots \times V_n \) satisfying the parity condition: the cardinality of \( \Omega \cap (X_1 \times \cdots \times X_n) \) is even if \( X_i \subseteq V_i \) and \( |X_i| = 2 \) for all \( i \in \{1, \ldots, n\} \).

We use the terminology of hypergraphs to describe an octahedral system: the sets \( V_i \) are the classes, the elements in \( V_i \) are the vertices, and the \( n \)-tuples in \( V_1 \times \cdots \times V_n \) are the edges. An edge whose \( i \)-th component is a vertex \( x \in V_i \) is incident with the vertex \( x \), and conversely. A vertex \( x \) incident with no edges is isolated. A class \( V_i \) is covered if each vertex of \( V_i \) is incident with at least one edge. Finally, the set of edges incident with \( x \) is denoted by \( \delta_{\Omega}(x) \) and the degree of \( x \), denoted by \( \text{deg}_{\Omega}(x) \), refers to \( |\delta_{\Omega}(x)| \).

**Lemma 1.** In every nonempty octahedral system, at least one class is covered.

**Proof.** Consider an octahedral system \( \Omega \subseteq V_1 \times \cdots \times V_n \). Suppose that no classes are covered. There is at least one isolated vertex \( x_i \) in each \( V_i \). Hence, if there were an edge \((y_1, \ldots, y_n)\) in \( \Omega \), then the parity condition would not be satisfied for \( X_i = \{x_i, y_i\} \). \( \square \)

Given a colourful point configuration \( S_1, \ldots, S_{d+1} \), the Octahedron Lemma [2, 3] states that, for any \( S'_1 \subseteq S_1, \ldots, S'_{d+1} \subseteq S_{d+1} \), with \( |S'_1| = \cdots = |S'_{d+1}| = 2 \), the number of colourful simplices generated by \( \bigcup_{i=1}^{d+1} S'_i \) and containing \( 0 \) in their convex hulls is even. The hypergraph over \( V_1 \times \cdots \times V_n \) where \( V_i \) is identified with \( S_i \) and whose edges are identified with the colourful simplices containing \( 0 \) in their convex hulls is therefore an octahedral system. Furthermore, a strengthening of the colourful Carathéodory Theorem, given in [1], states that if \( 0 \in \bigcap_{i=1}^{d+1} \text{conv}(S_i) \), then each point of the colourful point configuration is in some colourful simplices containing \( 0 \) in their convex hulls. Hence, in an octahedral system \( \Omega \) arising from such a colourful point configuration, each class \( V_i \) is covered.

2.2. Decompositions. The following proposition, proved in [5], states that the set of all octahedral systems is stable under the “symmetric difference” operation.

**Proposition 1.** Let \( \Omega \) and \( \Omega' \) be two octahedral systems over the same vertex set. \( \Omega \triangle \Omega' \) is an octahedral system.

**Proof.** Let \( \Omega'' = \Omega \triangle \Omega' \). As \( \Omega'' \) is a subset of \( V_1 \times \cdots \times V_n \), we simply check that the parity condition is satisfied. Consider \( X_1 \subseteq V_1, \ldots, X_n \subseteq V_n \) with \( |X_i| = 2 \) for \( i = 1, \ldots, n \). We have

\[
|\Omega'' \cap (X_1 \times \cdots \times X_n)| = |\Omega \cap (X_1 \times \cdots \times X_n)| + |\Omega' \cap (X_1 \times \cdots \times X_n)| - 2|\Omega \cap \Omega' \cap (X_1 \times \cdots \times X_n)|.
\]

All the terms of the sum are even, which allows to conclude. \( \square \)

We now present a family of specific octahedral systems we call umbrellas. An umbrella \( U \) is a set of the form \( \{x^{(1)}\} \times \cdots \times \{x^{(i-1)}\} \times V_i \times \{x^{(i+1)}\} \times \cdots \times \{x^{(n)}\} \), with \( x^{(j)} \in V_j \) for \( j \neq i \). The class \( V_i \) covered in \( U \) is called its colour. \( T = (x^{(1)}, \ldots, x^{(i-1)}, x^{(i+1)}, \ldots, x^{(n)}) \) is its transversal. An umbrella is clearly an octahedral system over \( V_1 \times \cdots \times V_n \) and we have the following proposition.

**Proposition 2.** Two umbrellas of the same colour have an edge in common if and only if they are equal.
Proof. An umbrella is entirely determined by its colour \(V_i\) and its transversal \(T\). Therefore, if two umbrellas of the same colour have an edge in common, they necessarily have the same transversal, which implies that they are equal.

It was implicitly proved in Section 3 of [5] that any octahedral system can be described as a symmetric difference of umbrellas. In this paper, we describe an octahedral system as a symmetric difference of other octahedral systems to bound its cardinality.

Consider a nonempty octahedral system \(\Omega \subseteq V_1 \times \cdots \times V_n\) with \(|V_i| = n\) for all \(i \in \{1, \ldots, n\}\). Denote by \(i_1\) the smallest \(i \in \{1, \ldots, n\}\) such that \(V_i\) is covered in \(\Omega\) and order the vertices \(\{x_{i1}, \ldots, x_{in}\}\) of \(V_{i_1}\) by increasing degree: \(\deg_\Omega(x_{i1}) \leq \cdots \leq \deg_\Omega(x_{in})\). We define \(\mathcal{U}\) to be the set of umbrellas of colour \(V_{i_1}\) containing an edge of \(\Omega\) incident with \(x_{i_1}\) and \(W = \Delta_{U \in \mathcal{U}} U\). Let \(\Omega_j\) be the set of all edges in \(\Omega \Delta W\) incident with \(x_j\). Formally,

\[
\mathcal{U} = \{U : U\text{ umbrella of colour } V_{i_1}\text{ and } U \cap \delta_\Omega(x_{i_1}) \neq \emptyset\} \text{ and } \Omega_j = \delta_{\Omega \Delta W}(x_j).
\]

Note that \(|\mathcal{U}| = \deg_\Omega(x_{i_1})\). In the remaining of the paper we refer to \((\mathcal{U}, \Omega_2, \ldots, \Omega_n)\) as a suitable decomposition.

Lemma 2. Let \((\mathcal{U}, \Omega_2, \ldots, \Omega_n)\) be suitable decomposition and let \(W = \Delta_{U \in \mathcal{U}} U\). We have

(i) \(\Omega_j \cap \Omega_\ell = \emptyset\), for all \(j \neq \ell\) (they have no edge in common),

(ii) \(\Omega = W \Delta \Omega_2 \Delta \cdots \Delta \Omega_n\),

(iii) \(\Omega_j\) is an octahedral system, for all \(j\),

(iv) \(\deg_\Omega(x_j) \geq \max(|\mathcal{U}|, |\Omega_j| - |\Omega_j \cap W|)\) for all \(j\).

(v) If \(V_i\) is not covered in \(\Omega\), then \(V_i\) is not covered in \(\Omega \Delta W\) and \(V_i\) is covered in no \(\Omega_j\).

The terminology suitable decomposition is due to point (ii) of Lemma 2.

Proof of Lemma 2. We first prove (i). The \(i_1\)th component of any edge in \(\Omega_j\) is \(x_j\). Therefore, \(\Omega_j\) and \(\Omega_\ell\) have no edge in common if \(j \neq \ell\).

We then prove (ii). There are exactly \(\deg_\Omega(x_{i_1})\) umbrellas of colour \(V_{i_1}\) containing an edge of \(\Omega\) incident with \(x_{i_1}\). As \(W\) is the symmetric difference of these umbrellas, \(x_{i_1}\) is isolated in \(\Omega \Delta W\). Thus, \(\Omega_2, \ldots, \Omega_n\) form a partition of the edges in \(\Omega \Delta W\) and \(\Omega \Delta W = \Omega_2 \Delta \cdots \Delta \Omega_n\). Taking the symmetric difference of this equality with \(W\) we obtain \(\Omega = W \Delta \Omega_2 \Delta \cdots \Delta \Omega_n\).

We now prove (iii). By definition, the \(\Omega_j\)’s are subsets of \(V_1 \times \cdots \times V_n\). It remains to prove that they satisfy the parity condition. Consider \(X_i \subseteq V_i\) with \(|X_i| = 2\) for \(i = 1, \ldots, n\). If \(X_{i_1}\) does not contain \(x_j\), there are no edges in \(\Omega_j\) induced by \(X_1 \times \cdots \times X_n\). If \(X_{i_1}\) contains \(x_j\), the edges in \(\Omega_j\) induced by \(X_1 \times \cdots \times X_n\) are the ones induced by \(X_1 \times \cdots \times X_{i_1-1} \times \{x_j\} \times X_{i_1+1} \times \cdots \times X_n\). As \(x_{i_1}\) is isolated in \(\Omega \Delta W\), those edges are exactly the edges in \(\Omega \Delta W\) induced by \(X_1 \times \cdots \times X_{i_1-1} \times \{x_1, x_j\} \times X_{i_1+1} \times \cdots \times X_n\). According to Proposition 1, \(W\) is an octahedral system and \(\Omega \Delta W\) as well, hence there is an even number of edges.

We prove (iv). We have \(|\mathcal{U}| = \deg_\Omega(x_{i_1})\leq \deg_\Omega(x_j)\) for all \(j \in \{1, \ldots, n\}\). Furthermore, by definition of the symmetric difference, we have \((\Omega_2 \Delta \cdots \Delta \Omega_n) \setminus W \subseteq \Omega\). This inclusion becomes \((\Omega_2 \setminus W) \Delta \cdots \Delta (\Omega_n \setminus W) \subseteq \Omega\). As two \(\Omega_j\)’s share no edges, \(\Omega_j \setminus W \subseteq \Omega\) and thus \(\Omega_j \setminus W \subseteq \delta_\Omega(x_j)\) for all \(j \in \{2, \ldots, n\}\). We obtain

\[
|\Omega_j| - |\Omega_j \cap W| \leq \deg_\Omega(x_j).
\]

Finally to prove (v) it suffices to prove that a class \(V_i\) not covered in \(\Omega\) remains not covered in \(\Omega \Delta W\). Indeed, if a class is covered in an \(\Omega_j\), it is also covered in \(\Omega \Delta W\), as no
two $\Omega_i$’s have an edge in common. Consider $V_i$ not covered in $\Omega$. There is a vertex $x \in V_i$ incident with no edges in $\Omega$. In particular, there are no edges in $\Omega$ incident with $x_1$ and $x$. Therefore, the umbrellas in $\mathcal{U}$, which are defined by the edges incident with $x_1$, contain no edges incident with $x$. Hence, $x$ is isolated in $W = \Delta_{U \in \mathcal{U}}U$ and in $\Omega$. Finally, $x$ remains isolated in $\Omega \triangle W$.  

Unlike the suitable decomposition of $\Omega$, which is a decomposition over general octahedral systems, the decomposition given in the following lemma is over umbrellas.

**Lemma 3.** Consider an octahedral system $\Omega \subseteq V_1 \times \cdots \times V_n$ with $|V_i| = n$ for all $i \in \{1, \ldots, n\}$. There exists a set of umbrellas $\mathcal{D}$, such that $\Omega = \Delta_{U \in \mathcal{D}}U$ and such that the following implication holds: 

$$V_i \text{ is the colour of some } U \in \mathcal{D} \implies V_i \text{ is covered in } \Omega.$$ 

**Proof.** The proof works by induction on the number of covered classes in $\Omega$. If no classes are covered, then, according to Lemma 1, $\Omega$ is empty.

Suppose now that $k$ classes are covered, with $k \geq 1$, and consider a suitable decomposition $(\mathcal{U}, \Omega_2, \ldots, \Omega_n)$ of $\Omega$. Denote by $W$ the symmetric difference $W = \Delta_{U \in \mathcal{U}}U$. According to Proposition 1, $W$ is an octahedral system, and so is $\Omega \triangle W$. There are strictly fewer covered classes in $\Omega \triangle W$ than in $\Omega$. Indeed, in $\Omega \triangle W$, the class $V_{i_1}$ is no longer covered, since $x_1$ is isolated, and according to (v) of Lemma 2, a class not covered in $\Omega$ remains not covered in $\Omega \triangle W$. By induction, there exists a set $\mathcal{D}'$ of umbrellas such that $\Omega \triangle W = \Delta_{U \in \mathcal{D}'}U$, and such that if there is an umbrella of colour $V_i$ in $\mathcal{D}'$, then $V_i$ is covered in $\Omega \triangle W$. As the umbrellas in $\mathcal{D}'$ are not of colour $V_{i_1}$, we have $\mathcal{U} \cap \mathcal{D}' = \emptyset$. Therefore, $\Omega = (\Delta_{U \in \mathcal{U}}U) \triangle (\Delta_{U \in \mathcal{D}'}U)$ and the set $\mathcal{D} = \mathcal{U} \cup \mathcal{D}'$ satisfies the statement of the lemma. \hfill $\Box$

### 3. Proof of the Main Result

The following theorem gives a general lower bound on the cardinality of an octahedral system. Our main theorem is a corollary of it.

**Theorem 2.** Let $\Omega \subseteq V_1 \times \cdots \times V_n$ be an octahedral system with $|V_1| = \cdots = |V_n| = n \geq 2$. If $k \geq 1$ classes among the $V_i$’s are covered, then 

$$|\Omega| \geq k(n - 2) + 2.$$ 

Before proving this theorem, we show how the main theorem can be deduced from it.

**Proof of Theorem 1.** The inequality $\mu(d) \leq d^2 + 1$ is proved in [3]. Let $S_1, \ldots, S_{d+1}$ be a colourful point configuration in $\mathbb{R}^d$. As explained in Section 2.1, the set $\Omega \subseteq V_1 \times \cdots \times V_{d+1}$, with $V_i = S_i$ for $i = 1, \ldots, d + 1$ and whose edges correspond to the colourful simplices containing $0$ in their convex hulls, is an octahedral system. According to [1, Theorem 2.3.], all the classes are covered in this octahedral system. Applying Theorem 2 with $k = n = d + 1$ gives the lower bound: $\mu(d) \geq d^2 + 1$. \hfill $\Box$

The remainder of the section is devoted to the proof of Theorem 2. The proof distinguishes two cases, corresponding to the following Propositions 3 and 4. We first prove these propositions.

**Proposition 3.** Consider an octahedral system $\Omega \subseteq V_1 \times \cdots \times V_n$ with $|V_i| = n$ for all $i \in \{1, \ldots, n\}$ and a class $V_i$ covered in $\Omega$. If $\Omega$ can be written as a symmetric difference of umbrellas, none of them being of colour $V_i$, then $|\Omega| \geq n^2$. 

Proposition 4. Consider an octahedral system \( \Delta \subseteq V_1 \times \cdots \times V_n \) with \( |V_i| = n \) for all \( i \in \{1, \ldots, n\} \) and a suitable decomposition \( (\mathcal{U}, \Omega_1, \Omega_2, \ldots, \Omega_n) \) of \( \Omega \). Let \( \mathcal{O} \subseteq \{\Omega_2, \ldots, \Omega_n\} \) such that for each \( \Omega_j \in \mathcal{O} \) there is a class \( V_i \) covered in \( \Omega_j \) and in no other \( \Omega_{\ell} \in \mathcal{O} \). Denote by \( P \subseteq \mathcal{O} \) the set of umbrellas in \( \mathcal{O} \). We have

\[
|\Omega| \geq |\mathcal{U}|(n - |\mathcal{O}|) + \sum_{\Omega_j \in \mathcal{O}} |\Omega_j| - |\mathcal{U}|(|\mathcal{O}| - |P|) - |\mathcal{U}| - |P| + 1.
\]

Proof. Let \( W = \Delta_{U \in \mathcal{U}} U \). The number of edges in \( \Omega \) is equal to \( \sum_{j=1}^n \deg_{\Omega}(x_j) \). We bound \( \deg_{\Omega}(x_j) \) by \( |\mathcal{U}| \) for \( j = 1 \) and if \( \Omega_j \notin \mathcal{O} \) and by \( |\Omega_j| - |\Omega_j \cap W| \) otherwise, see (iv) in Lemma 2. We obtain

\[
|\Omega| \geq |\mathcal{U}|(n - |\mathcal{O}|) + \sum_{\Omega_j \in \mathcal{O}} (|\Omega_j| - |\Omega_j \cap W|).
\]

We introduce a graph \( G = (\mathcal{V}, \mathcal{E}) \) defined as follows. We use the terminology nodes and links for \( G \) in order to avoid confusion with the vertices and edges of \( \Omega \). The nodes in \( \mathcal{V} \) are identified with the umbrellas in \( \mathcal{U} \) and the \( \Omega_j \)'s in \( \mathcal{O} \): \( \mathcal{V} = \mathcal{U} \cup \mathcal{O} \). There is a link in \( \mathcal{E} \) between two nodes if the corresponding octahedral systems have an edge in common. \( G \) is bipartite: indeed, two umbrellas in \( \mathcal{U} \) are of the same colour \( V_i \) and, according to Proposition 2, they do not have an edge in common. According to Lemma 2, two \( \Omega_j \)'s do not have an edge in common either.

For \( \Omega_j \) in \( \mathcal{O} \), we have \( |\Omega_j \cap W| = \sum_{U \in \mathcal{U}} |\Omega_j \cap U| = \deg_G(\Omega_j) \), note that here the degree is counted in \( G \). The fact that the umbrellas in \( \mathcal{U} \) are disjoint proves the first equality. The second inequality is deduced from the facts that \( \Omega_j \) has at most one edge in common with each umbrella in \( \mathcal{U} \), the one incident with \( x_j \), and that \( \Omega_j \) has no neighbours in \( \mathcal{O} \). We obtain the following bound

\[
|\Omega| \geq |\mathcal{U}|(n - |\mathcal{O}|) + \sum_{\Omega_j \in \mathcal{O}} (|\Omega_j| - \deg_G(\Omega_j))

= |\mathcal{U}|(n - |\mathcal{O}|) + \sum_{\Omega_j \in \mathcal{O}} |\Omega_j| - \deg_G(\mathcal{O} \setminus \mathcal{P}) - \deg_G(\mathcal{P}).
\]

Again, for the equality, we use the fact \( G \) is bipartite. The number of links in \( \mathcal{E} \) incident with a node in \( \mathcal{O} \setminus \mathcal{P} \) is at most \( |\mathcal{U}| \). Hence, \( \deg_G(\mathcal{O} \setminus \mathcal{P}) \leq |\mathcal{U}|(|\mathcal{O}| - |\mathcal{P}|) \). It remains to bound \( \deg_G(\mathcal{P}) \). Note that if \( U \) is an umbrella in \( \mathcal{P} \), it is the only umbrella of its colour in
\( \mathcal{P} \), otherwise it would contradict the property of \( \mathcal{O} \). We now prove that there are no cycles induced by \( \mathcal{P} \cup \mathcal{U} \) in \( G \).

Suppose there is such a cycle \( \mathcal{C} \) and consider an umbrella \( U \) of \( \mathcal{P} \) in this cycle. Denote its colour by \( V_i \) and its neighbours in \( \mathcal{C} \) by \( L \) and \( R \). As \( G \) is simple, \( L \) and \( R \) are distinct. \( L \) and \( R \) are both in \( \mathcal{U} \), and hence are of colour \( V_i \) and do not have an edge in common. Therefore \( U \cap L \) and \( U \cap R \) do not have an edge in common either, which implies that the \( i \)th component of the transversals of \( L \) and \( R \) are distinct. Note that two umbrellas adjacent in \( \mathcal{C} \), both of colour distinct from \( V_i \), have necessarily transversals with the same \( i \)th component. Hence there must be another umbrella of colour \( V_i \) in the path in \( \mathcal{C} \) between \( L \) and \( R \) not containing \( U \). This is a contradiction since \( U \) is the only umbrella in \( \mathcal{P} \) of colour \( V_i \).

The number of links in \( \mathcal{E} \) incident with \( \mathcal{P} \) is then at most \(|\mathcal{U}| + |\mathcal{P}| - 1 \). This allows us to conclude.

\[ \square \]

**Proof of Theorem 2.** Let \( \Omega \subseteq V_1 \times \cdots \times V_n \) be an octahedral system with \(|V_1| = \cdots = |V_n| = n \geq 2 \), and suppose that \( k \geq 1 \) classes \( V_{i_1}, \ldots, V_{i_k} \), with \( i_1 < \cdots < i_k \), are covered in \( \Omega \). The proof works by induction on \( k \).

If \( k = 1 \), then \( \Omega \) must contain at least \( n \) edges for one class to be covered.

Assume now that \( k > 1 \). If \(|\mathcal{U}| \geq n - 1 \), then, according to (iv) of Lemma 2, \(|\Omega| = \sum_{j=1}^{n} \deg_{\Omega}(x_j) \geq n|\mathcal{U}| \geq k(n-2) + 2 \) and we are done. Assume now that \(|\mathcal{U}| \leq n - 2 \). We consider a suitable decomposition \((\mathcal{U}, \Omega_2, \ldots, \Omega_n)\) of \( \Omega \) and distinguish two cases.

Case 1: *One of the covered classes \( V_i \), for \( i \in \{i_2, \ldots, i_k\} \), is not covered in any \( \Omega_j \).* Let \( V_i \) be a covered class in \( \Omega \), while not being covered in any \( \Omega_j \). For each \( j \in \{2, \ldots, n\} \), applying Lemma 3 on \( \Omega_j \) gives a set \( \mathcal{D}_j \) of umbrellas, all of colour distinct from \( V_i \), such that \( \Omega_j = \Delta_{U \in \mathcal{D}_j} U \). We obtain \( \Omega = (\Delta_{U \in \mathcal{U}} U) \Delta_{j=2}^{n} \Delta_{U \in \mathcal{D}_j} U \), according to (ii) of Lemma 2. Thus, we can apply Proposition 3 which ensures that

\[ |\Omega| \geq n^2 \geq k(n-2) + 2. \]

Case 2: *Each covered class \( V_i \), for \( i \in \{i_2, \ldots, i_k\} \), is covered in at least one of the \( \Omega_j \).* Choose a set \( \mathcal{O} \subseteq \{\Omega_2, \ldots, \Omega_n\} \), minimal for inclusion, such that each covered class \( V_i \), for \( i \in \{i_2, \ldots, i_k\} \), is covered in at least one of the \( \Omega_j \in \mathcal{O} \). Such a set \( \mathcal{O} \) satisfies the statement of Proposition 4. Applying this proposition, we obtain

\[ |\Omega| \geq |\mathcal{U}|(n - |\mathcal{O}|) + \sum_{\Omega_j \in \mathcal{O}} |\Omega_j| - |\mathcal{U}|(|\mathcal{O}| - |\mathcal{P}|) - |\mathcal{U}| - |\mathcal{P}| + 1. \]

We now bound \( \sum_{\Omega_j \in \mathcal{O}} |\Omega_j| \). By minimality of \( \mathcal{O} \), there is at least one class covered in each \( \Omega_j \in \mathcal{O} \). By induction, the cardinality of \( \Omega_j \) is at least \( k_j(n-2) + 2 \), where \( k_j \geq 1 \) is the number of covered classes in \( \Omega_j \). We have \( k_j < k \) according to (v) of Lemma 2. This lower bound is not good enough for the \( \Omega_j \notin \mathcal{P} \) such that \( k_j = 1 \). We denote by \( \mathcal{A} \) those \( \Omega_j \)'s. We explain now how to improve the lower bound for \( \Omega_j \in \mathcal{A} \). Only one class is covered in \( \Omega_j \) and \( \Omega_j \notin \mathcal{P} \). According to Lemma 3, \( \Omega_j \) can be written as a symmetric difference of distinct umbrellas of the same colour. According to Proposition 2, these umbrellas are pairwise disjoint and \( |\Omega_j| \) is equal to \( n \) times the number of umbrellas in this decomposition. Since \( \Omega_j \) is not an umbrella itself, otherwise \( \Omega_j \) would have been in \( \mathcal{P} \), there are at least two
umbrellas in this decomposition. We obtain

\[
\sum_{\Omega_j \in \mathcal{O}} |\Omega_j| \geq \left( \sum_{\Omega_j \in \mathcal{O} \setminus \mathcal{A}} k_j \right) (n - 2) + 2|\mathcal{O} \setminus \mathcal{A}| + 2n|\mathcal{A}| = \left( \sum_{\Omega_j \in \mathcal{O}} k_j \right) (n - 2) + 2|\mathcal{O}| + n|\mathcal{A}|
\]

We have thus

\[
|\Omega| \geq |U|(n - |\mathcal{O}|) + \left( \sum_{\Omega_j \in \mathcal{O}} k_j \right) (n - 2) + 2|\mathcal{O}| + n|\mathcal{A}| - |U|(|\mathcal{O}| - |\mathcal{P}|) - |U| - |\mathcal{P}| + 1.
\]

Finally, we have

\[
(1) \quad 2|\mathcal{O}| - |\mathcal{P}| - |\mathcal{A}| \leq \sum_{\Omega_j \in \mathcal{O}} k_j
\]

\[
(2) \quad k - 1 \leq \sum_{\Omega_j \in \mathcal{O}} k_j
\]

Equation (1) is obtained by distinguishing the \(\Omega_j\) with \(k_j = 1\) from those with \(k_j \geq 2\). Equation (2) results from the fact that each class \(V_{i_2}, \ldots, V_{i_k}\) is covered in at least one \(\Omega_j\) in \(\mathcal{O}\). Thus,

\[
|\Omega| \geq |U|(n - |\mathcal{O}|) + \left( \sum_{\Omega_j \in \mathcal{O}} k_j \right) (n - 2) + 2|\mathcal{O}| + |U||\mathcal{A}| - |U|(|\mathcal{O}| - |\mathcal{P}|) - |U| - |\mathcal{P}| + 1
\]

\[
\geq (k - 1)(n - 2) + 2|\mathcal{O}| - |\mathcal{P}| + 1 + \left( \sum_{\Omega_j \in \mathcal{O}} k_j - k + |\mathcal{A}| + n - 2|\mathcal{O}| + |\mathcal{P}| \right) |U|
\]

where we only used the inequalities \(n \geq n - 2 \geq |U|\) and (2). According to (1), the expression \(\left( \sum_{\Omega_j \in \mathcal{O}} k_j - k + |\mathcal{A}| + n - 2|\mathcal{O}| + |\mathcal{P}| \right) \) is nonnegative. Moreover, we have already noted that \(|U| = \deg_{\Omega}(x_1)\), which is at least 1. Therefore,

\[
|\Omega| \geq (k - 1)(n - 2) + 2|\mathcal{O}| - |\mathcal{P}| + 1 + \sum_{\Omega_j \in \mathcal{O}} k_j - k + |\mathcal{A}| + n - 2|\mathcal{O}| + |\mathcal{P}|
\]

Using (2) again, we obtain

\[
|\Omega| \geq k(n - 2) + 2.
\]

\[\square\]

Aknowlegement

The author thanks Antoine Deza for introducing her to the colourful simplicial depth conjecture and Frédéric Meunier for his thorough reading of the manuscript and his helpful comments.
