Abstract

Generalization, also called anti-unification, is the dual of unification. Given terms $t$ and $t'$, a generalization is a term $t''$ of which $t$ and $t'$ are substitution instances. The dual of a most general unifier (mgu) is that of least general generalization (lgg). In this work, we extend the known untyped generalization algorithm to, first, an order-sorted typed setting with sorts, sub sorts, and subtype polymorphism; second, we extend it to work modulo equational theories, where function symbols can obey any combination of associativity, commutativity, and identity axioms (including the empty set of such axioms); and third, to the combination of both, which results in a modular, order-sorted equational generalization algorithm. Unlike the untyped case, there is in general no single lgg in our framework, due to order-sortedness or to the equational axioms. Instead, there is a finite, minimal set of lggs, so that any other generalization has at least one of them as an instance. Our generalization algorithms are expressed by means of inference systems for which we give proofs of correctness. This opens up new applications to partial evaluation, program synthesis, and theorem proving for typed equational reasoning systems and typed rule-based languages such as ASF+SDF, Elan, OBJ, Cafe-OBJ, and Maude.

1. Introduction

Generalization is a formal reasoning component of many symbolic frameworks, including theorem provers, and automatic program analysis, synthesis, verification, compilation, refactoring, test case generation, learning, specialisation, and transformation techniques see, e.g., (Boyer and Moore, 1980a; Buly...
Generalization, also called anti-unification, is the dual of unification. Given terms \( t \) and \( t' \), a generalization of \( t \) and \( t' \) is a term \( t'' \) of which \( t \) and \( t' \) are substitution instances.

The dual of a most general unifier (mgu) is that of a least general generalization (lgg), that is, a generalization that is more specific than any other generalization. Whereas unification produces most general unifiers that, when applied to two expressions, make them equivalent to the most general common instance of the inputs (Lassez et al., 1988), generalization abstracts the inputs by computing their most specific generalization. As in unification, where the most general unifier (mgu) is of interest, in the sequel we are interested in the least general generalization (lgg) or, as we shall see for the order-sorted, equational case treated in this article, in a minimal and complete set of lgg joins, which is the dual analogue of a minimal and complete set of unifiers for equational unification problems (Baader and Snyder, 1999).

As an important application, generalization is a relevant component for ensuring termination of program manipulation techniques such as automatic program analysis, synthesis, specialisation and transformation, in automatic theorem proving, logic programming, typed lambda calculus, term rewriting, etc. For instance, in the partial evaluation (PE) of logic programs (Gallagher, 1993), the general idea is to construct a set of finite (possibly partial) deduction trees for a set of initial function calls (i.e., generic function calls using logical variables), and then extract from those trees a new program \( P \) that allows any instance of the initial calls to be executed. To ensure that the partially evaluated program \( P \) covers all the possible initial function calls, most PE procedures recursively add other function calls that show up dynamically during the process of constructing the deduction trees for the set of calls to be specialized. This process could go on forever by adding more and more function calls that have to be specialized and thus it requires some kind of generalization in order to enforce the termination of the process: if a call occurring in \( P \) that is not sufficiently covered by the program embeds an already evaluated call, then both calls are generalized by computing their lgg and the specialization process is restarted from the generalized call, ensuring that both calls will be covered by the new resulting partially evaluated program.

The computation of lgg joins is also central to most program synthesis and learning algorithms such as those developed in the area of inductive logic programming (Muggleton, 1999), and also to conjecture lemmas in inductive theorem provers such as Nqthm (Boyer and Moore, 1980b) and its ACL2 extension (Kaufmann et al., 2000a). In the literature on machine learning and partial evaluation, least general generalization is also known as most specific generalization (msg) and least common anti-instance (lcai) (Mogensen, 2000). Least general generalization was originally introduced by Plotkin in (Plotkin, 1970), see also (Reynolds, 1970). Actually, Plotkin’s work originated from the consideration in (Popplestone, 1969) that, since unification is useful in automatic deduction by the resolution method, its dual might prove helpful for induction. Anti-unification is also used in test case generation techniques to achieve appropriate
coverage [Belli and Jack 1998]. Applications of generalization to invariant generation and software clone detection are described in (Bulychev et al., 2010). Suggestion for auxiliary lemmas in equational inductive proofs, computation of construction laws for given term sequences, and learning of screen editor command sequences by using generalization are discussed in (Burghardt, 2005).

To the best of our knowledge, most previous generalization algorithms assume an untyped setting; two notable exceptions are the generalization in the higher-order setting of the calculus of constructions of (Pfenning, 1991), and the order-sorted feature term generalization of (Aït-Kaci 1983; Aït-Kaci and Sasaki, 2001). However, many applications, for example to partial evaluation, theorem proving, and program learning, for typed rule-based languages such as ASF+SDF (Bergstra et al., 1989), Elan (Borovanský et al., 2002), OBJ (Goguen et al., 2000), CafeOBJ (Diaconescu and Futatsugi, 1998), and Maude (Clavel et al., 2007), require a first-order typed version of generalization which does not seem to be available: we are not aware of any existing algorithm. Moreover, several of the above-mentioned languages have an expressive order-sorted typed setting with sorts, subsorts (where subsort inclusions form a partial order and are interpreted semantically as set-theoretic inclusions of the corresponding data sets), and subsort-overloaded function symbols (a feature also known as subtype polymorphism), so that a symbol, for example +, can simultaneously exist for various sorts in the same subsort hierarchy, such as + for natural, integers, and rationals, and its semantic interpretations agree on common data items. Because of its support for order-sorted specifications, our generalization algorithm can be applied to generalization problems in all the above-mentioned rule-based languages.

Also, quite often all the above mentioned applications of generalization may have to be carried out in contexts in which the function symbols satisfy certain equational axioms. For example, in rule-based languages such as ASF+SDF (Bergstra et al., 1989), Elan (Borovanský et al., 2002), OBJ (Goguen et al., 2000), CafeOBJ (Diaconescu and Futatsugi, 1998), and Maude (Clavel et al., 2007) some function symbols may be declared to obey given algebraic laws (the so-called equational attributes of associativity and/or commutativity and/or identity in OBJ, CafeOBJ and Maude), whose effect is to compute with equivalence classes modulo such axioms while avoiding the risk of non-termination. Similarly, theorem provers, both general first-order logic ones and inductive theorem provers, routinely support commonly occurring equational theories for some function symbols such as associativity-commutativity. Again, our generalization algorithm applies to all such typed languages and theorem provers because of its support for associativity and/or commutativity and/or identity axioms.

Surprisingly, unlike order-sorted unification, equational unification, and order-sorted equational unification, which all the three have been thoroughly investigated in the literature — see, e.g., (Baader and Snyder, 1999; Meseguer et al., 1989; Schmidt-Schauß, 1986; Siekmann, 1989; Smolka et al., 1989) — to the best of our knowledge there seems to be no previous, systematic treatment of order-sorted generalization, equational generalization, and order-sorted
equational generalization, although some order-sorted cases and some unsorted equational cases have been studied (see below).

To better motivate our work, let us first recall the standard generalization problem. Let \( t_1 \) and \( t_2 \) be two terms. We want to find a term \( s \) that generalizes both \( t_1 \) and \( t_2 \). In other words, both \( t_1 \) and \( t_2 \) must be substitution instances of \( s \). Such a term is, in general, not unique. For example, let \( t_1 \) be the term \( f(f(a, a), b) \) and let \( t_2 \) be \( f(f(b, b), a) \). Then \( t = x \) trivially generalizes the two terms, with \( x \) being a variable. Another possible generalization is \( f(x, y) \), with \( y \) being also a variable. The term \( f(f(x, x), y) \) has the advantage of being the most ‘specific’ or least general generalization (lgg) (modulo variable renaming). Moreover, if we have order-sorted information in such a way that constant \( a \) is of sort \( A \), constant \( b \) is of sort \( B \), but symbol \( f \) has two definitions \( C \times C \to C \) and \( D \times D \to D \) where \( A \) and \( B \) are subsorts of \( C \) and \( D \), then there are four least general generalizations \( f(f(x, C, x), y, C), f(f(x, C, x), y, D), f(f(x, D, x), y, C), \) and \( f(f(x, D, x), y, D) \). If we have equational properties for symbol \( f \), for instance \( f \) being associative and commutative, and we disregard order-sorted information, then there are two least general generalizations \( f(x, x, y) \) and \( f(a, b, y) \), which are incomparable using associativity and commutativity. Finally, if we combine order-sorted information and equational properties, then there are six least general generalizations \( f(a, b, y, C), f(a, b, y, D), f(x, C, x, C, y, C), f(x, C, x, C, y, D) f(x, D, x, D, y, C), \) and \( f(x, D, x, D, y, D) \).

The extension of the generalization algorithm to deal with order-sorted functions and equational theories is nontrivial, because of two important reasons. First, as we mentioned the existence and uniqueness of a least general generalization is typically lost. There is a finite and minimal set of least general generalizations for two terms, so that any other generalization has at least one of those as an instance. Such a set of lgg's is the dual analogue of a minimal complete set of unifiers for non-unitary unification algorithms, such as those for order-sorted unification, e.g., \( \text{Meseguer et al. 1989} \) \( \text{Schmidt-Schauss 1986} \) \( \text{Smolka et al. 1989} \), and for equational unification, see, e.g., \( \text{Baader and Snyder 1999} \) \( \text{Siekmann 1989} \). Second, similarly to the case of equational unification \( \text{Siekmann 1989} \), computing least general generalizations modulo an equational theory \( E \) is a difficult task due to the combinatorial explosion. Depending on the theory \( E \), a generalization problem may be undecidable, and even if it is decidable, may have infinitely many solutions.

This article develops several generalization algorithms: an order-sorted generalization algorithm, a modular \( E \)-generalization algorithm, and the combined version of both algorithms. In this article, we do not address the \( E \)-generalization problem in its fullest generality. Our modular \( E \)-generalization algorithm works for a parametric family of theories \( (\Sigma, E) \) such that any binary function symbol \( f \in \Sigma \) can have any combination of the following axioms: (i) associativity \((A_f)\) \( f(x, f(y, z)) = f(f(x, y), z) \); (ii) commutativity \((C_f)\) \( f(x, y) = f(y, x) \), and (iii) identity \((U_f)\) for a constant symbol, say, \( e \), i.e., \( f(x, e) = x \) and \( f(e, x) = x \). In particular, \( f \) may not satisfy any such axioms, which when it happens for all binary symbols \( f \in \Sigma \) gives us the standard, syntactic (order-sorted) generalization algorithm as a special case. As it is
usual in current treatments of different formal deduction mechanisms, and has become standard for the dual case of unification algorithms since Martelli and Montanari—see, e.g., (Jouannaud and Kirchner, 1991; Martelli and Montanari, 1982)—we specify each generalization process by means of an inference system rather than by an imperative-style algorithm.

**Our contribution and plan of the paper**

After some preliminaries in Section 2, we recall in Section 3 a syntactic unsorted generalization algorithm as a special case to motivate later extensions. The main contributions of the paper can be summarized as follows:

1. An order-sorted generalization algorithm (in Section 4). If two terms are related in the sort ordering (their sorts are both in the same connected component of the partial order of sorts), then there is in general no single lgg, but the algorithm computes a finite and minimal set of least general generalizations, so that any other generalization has at least one of those as an instance. Such a set of lgg's is the dual analogue of a minimal and complete set of unifiers for non-unitary unification algorithms, such as those for order-sorted unification.

2. A modular equational generalization algorithm (in Section 5). Indeed, we provide different generalization algorithms—one for each kind of equational axiom—but the overall algorithm is modular in the precise sense that the combination of different equational axioms for different function symbols is automatic and seamless: the inference rules can be applied to generalization problems involving each symbol with no need whatsoever for any changes or adaptations. This is similar to, but much simpler and easier than, modular methods for combining E-unification algorithms, e.g., (Baader and Snyder, 1999). To the best of our knowledge, ours are the first equational least general generalization algorithms in the literature. An interesting result is that associative generalization is finitary, whereas associative unification is infinitary.

3. An order-sorted modular equational generalization algorithm (in Section 6), which combines and refines the inference rules given in Sections 4 and 5.

4. Formal correctness, completeness, and termination results for all the above generalization algorithms.

5. In Section 7, we present an implementation of the order-sorted, modular equational generalization algorithm, which is publicly available in the Maude system, followed by some conclusions and directions for future work in Section 8.

This paper is an extended and improved version of (Alpuente et al., 2009a,b) which unifies both, the order-sorted generalization of (Alpuente et al., 2009b) and the equational generalization of (Alpuente et al., 2009a) into a novel and more powerful, combined algorithm. The proposed algorithms should be of interest to developers of rule-based languages, theorem provers and equational reasoning programs, as well as program manipulation tools such as program
analyzers, partial evaluators, test case generators, and machine learning tools, for (order-sorted) declarative languages and reasoning systems supporting commonly occurring equational axioms such as associativity, commutativity and identity in a built-in and efficient way. For instance, this includes many theorem provers, and a variety of rule-based languages such as ASF+SDF, OBJ, CafeOBJ, Elan, and Maude. Since the many-sorted and unsorted settings are special instances of the order-sorted case, our algorithm applies a fortiori to those less expressive settings.

Related work

Generalization goes back to work of Plotkin [Plotkin, 1970], Reynolds [Reynolds, 1970], and Huet [Huet, 1976] and has been studied in detail by other authors; see for example the survey [Lassez et al., 1988]. Plotkin [Plotkin, 1970] and Reynolds [Reynolds, 1970] gave imperative-style algorithms for generalization, which are both essentially the same. Huet’s generalization algorithm [Huet, 1976], formulated as a pair of recursive equations, cannot be understood as an automated calculus due to some implicit assumptions in the treatment of variables. A deterministic reconstruction of Huet’s algorithm is given in [Østvold, 2004] which does not consider types either. A many-sorted generalization algorithm was presented in [Frisch and Jr., 1990] that is provided with the so-called S-sentences, which can be seen as a logical notation for encoding taxonomic (or ordering) information. Anti-unification for unranked terms, which differ from the standard ones by not having fixed arity for function symbols, and for finite sequences of such terms (called hedges) is investigated in [Kutsia et al., 2011]: efficiency of the algorithm is improved by imposing a rigidity function that is a parameter of the improved algorithm. The algorithm for higher-order generalization in the calculus of constructions of [Pfenning, 1991] does not consider order-sorted theories or equational axioms either, and for any two higher-order patterns, either there is no lgg (because the types are incomparable), or there is a unique lgg.

The significance of equational generalization was already pointed out by Pfenning in [Pfenning, 1991]: “It appears that the intuitiveness of generalizations can be significantly improved if anti-unification takes into account additional equations which come from the object theory under consideration. It is conceivable that there is an interesting theory of equational anti-unification to be discovered”. However, to the best of our knowledge, we are not aware of any existing equational generalization algorithm modulo the combination of associativity, commutativity and identity axioms. Actually, equational generalization has been absolutely neglected, except for the theory of associativity and commutativity [Pottier, 1989] (in french) and for commutative theories [Baader, 1991]. For the commutative case, [Baader, 1991] shows that all commutative theories are of generalization type ‘unitary’, but no generalization algorithm is provided. Pottier [Pottier, 1989] provides (unsorted) inference rules which mechanize generalization in AC theories, but these rules do not apply to the separate cases of C or A alone, nor to arbitrary combinations of the C, A, and U axioms. Finally, [Burghardt, 2005] presented a specially tailored algorithm.
that uses grammars to compute a finite representation of the (usually infinite) set of all E-generalizations of given terms, provided that E leads to regular congruence classes, which happens when E is the deductive closure of finitely many ground equations. However, as a natural consequence of representing equivalence classes of terms as regular tree grammars, the result of the E-generalization process is not a term, but a regular tree grammar of terms.

Least general generalization in an order-sorted typed setting was first investigated in (Aït-Kaci, 1983). A generalization algorithm is proposed in (Aït-Kaci, 1983) for feature terms, which are sorted, possibly nested, attribute-based structures which extend algebraic terms by relaxing the fixed arity and fixed indexing constraints. This is done by adding features (or attribute labels) to a sort as argument indicators. Feature terms (previously known as indexed terms or Ψ-terms) were originally proposed as flexible record structures for logic programming and then used to describe different data models, including attributed typed objects, in rule-based languages which are oriented towards applications to knowledge representation and natural language processing.

Since functor symbols of feature terms are ordered sorts, a feature term can be thought of as a type template which represents a set-denoting sort. By choosing to define types to be terms, and the type classification ordering to be term instantiation, the resulting type system is a lattice whose meet operation (i.e., greatest lower bound) w.r.t. the subsumption relation induced by the subset ordering (term instantiation) is first-order unification, and whose join operation (i.e., least upper bound) is first-order generalization. This model is familiar to Prolog programmers but unlike any other type system available in typed languages. Moreover, by considering a partial order on functors, the set of sorts is also given a pre-order structure. Intuitively, a feature term \( S \) is subsumed by a feature term \( T \) if \( S \) contains more information than \( T \), or, equivalently, \( S \) denotes a subset of \( T \). Under this subsumption order, the set of all feature terms is a prelattice provided the sort symbols are ordered as a lattice. Generalization is then defined as computing greater lower bounds in the prelattice of feature terms. The lgg of feature terms is also described in (Plaza, 1995). We also refer to (Plaza, 1995) for an account of several variants of feature descriptions, as used in computational linguistics and related areas, where generalization is recast as the retrieval of common structural similarity.

A rich description level is achieved when types are viewed as constraints. In this context, terms can be thought of as “crystallized” sintaxes that dissolve into a semantically equivalent conjunction of elementary constraints, best defined as a “soup”, thanks to the conjunction being associative and commutative. In the constraint setting, feature terms correspond to order-sorted feature (OSF) constraints in solved form (a normal form). Generalization in the OSF foundation is investigated in (Aït-Kaci and Sasaki, 2001), where an axiomatic definition of feature term generalization is provided, together with its operational realization. In the axiomatic definition, generalization is presented as an OSF-constraint construction process: the information conveyed by OSF terms is given an alternative, syntactic presentation by means of a constraint clause, and generalization is then defined by means of OSF clause generalization rules.
The lattice of partially ordered type structures of (Aït-Kaci 1983; Aït-Kaci and Sasaki 2001) and the order-sorted equational setting of rewriting logic (Meseguer 1997) differ in several aspects and are incomparable, i.e., one is not subsumed into the other. The differences, explained below, are based on term representation, sort structure, and algebraic axioms. The order-sorted type structure is much simpler and typically finite, whereas the association of a type to each feature term makes the set of types infinite. In the much simpler order-sorted setting, only the subsort relations between basic sorts need to be explicitly considered, although implicitly each term with variables can be interpreted set-theoretically as the set of its substitution instances. Obviously, by an encoding of first order terms as feature-terms —the features simply being argument positions, e.g., the term \( f(t_1, \ldots, t_n) \) if and only if the feature term \( f(1 \Rightarrow t_1, \ldots, n \Rightarrow t_n) \)— the order-sorted syntactic algorithm presented in (Alpuente et al. 2009b) could be seen as a special case of (Aït-Kaci 1983).

However, feature types can also be expressed as algebraic types if we supply the missing constructors for attributes, which are called implicit constructors in (Smolka and Aït-Kaci 1989). This encoding was used to develop a framework, based on equational constraint solving, where feature term unification and order-sorted term unification coexist. Thus, each term representations can be encoded into the other.

On the other hand, as already hinted at above, the sort structure is different in both approaches and, thus, the algorithm presented in (Aït-Kaci 2007) is different of what we present here. In (Aït-Kaci and Sasaki 2001), least upper bounds (lubs) are canonically represented as disjunctive sets of maximal terms: if one wants to specify that an element is of sort \( A \) or \( B \) when no explicit type symbol is known as their lub, then this element is induced to be of type \( A \lor B \). Instead, in an order-sorted setting (Goguen and Meseguer 1992; Meseguer 1998) the sort structure is much simpler, namely a (typically finite) poset as opposed to an infinite lattice. Yet, under the easily checkable assumption of preregularity (or \( E \)-preregularity for equational axioms \( E \) of associativity and/or commutativity and/or identity), each term (resp. each \( E \)-equivalence class of terms) has a least sort possible, see (Goguen and Meseguer 1992), and (Clavel et al. 2007, 22.2.5). Furthermore, unlike in the feature term case, there is no global assumption of a top sort, although each connected component in the poset of sorts can be conservatively extended with a top sort for that component (the so-called kinds, see (Clavel et al. 2007; Meseguer 1998) and Section 2). This means that certain generalization problems are regarded as incoherent and have no solution. For example, there is no generalization for the terms \( x: \text{Bool} \) and \( y: \text{Nat} \), assuming that the connected components of sorts for numbers (where \( \text{Nat} \) is one of the sorts) and truth values (where \( \text{Bool} \) is another sort) are disjoint. Thus, the sort structure contains different assumptions in each approach.

Finally, even if the comma (conjunction) is handled in the OSF as an associative-commutative operator, the OSF does not support the definition of operators with combinations of algebraic properties such as commutativity, associativity and identity, while each operator in our order-sorted setting can have any desired combination of these algebraic properties.
2. Preliminaries

We follow the classical notation and terminology from [TeReSc 2003] for term rewriting and from (Goguen and Meseguer 1992; Meseguer 1997) for order-sorted equational logic.

We assume an order-sorted signature $\Sigma$ with a finite poset of sorts $(S, \leq)$ and a finite number of function symbols. We furthermore assume a kind-completed signature such that: (i) each connected component in the poset ordering has a top sort, and for each $s \in S$ we denote by $[s]$ the top sort in the connected component of $s$, (i.e., if $s$ and $s'$ are sorts in the same connected component, then $[s] = [s']$); and (ii) for each operator declaration $f : s_1 \times \ldots \times s_n \rightarrow s$ in $\Sigma$, there is also a declaration $s_1 \rightarrow \ldots \rightarrow s_n \rightarrow s$ in $\Sigma$.

We assume pre-regularity of the signature $\Sigma$: for each operator declaration $f : s_1 \times \ldots \times s_n \rightarrow s$, and for the set $S_f$ containing sorts $s'$ appearing in operator declarations of the form $f : s'_1, \ldots, s'_n \rightarrow s'$ in $\Sigma$ such that $s_i \leq s'_i$ for $1 \leq i \leq n$, then the set $S_f$ has a least sort. The unique least sort of each $\Sigma$-term $t$ is denoted by $LS(t)$. Therefore, the top sort in the connected component of $LS(t)$ is denoted by $[LS(t)]$. Since the poset $(S, \leq)$ is finite and each connected component has a top sort, given any two sorts $s$ and $s'$ in the same connected component, the set of least upper bound sorts of $s$ and $s'$, although non necessarily a singleton set, always exists and is denoted by $\text{LUBS}(s, s')$.

Throughout this paper, we assume that $\Sigma$ has no ad-hoc operator overloading, i.e., any two operator declarations for the same symbol $f$ with equal number of arguments, $f : s_1 \times \ldots \times s_n \rightarrow s$ and $f : s'_1 \times \ldots \times s'_n \rightarrow s'$, must necessarily have $[s_1] = [s'_1], \ldots, [s_n] = [s'_n], [s] = [s']$.

We assume an $S$-sorted family $\mathcal{X} = \{X_s\}_{s \in S}$ of disjoint variable sets with each $X_s$ countably infinite. We write the sort associated to a variable explicitly with a colon and the sort, i.e., $x: \text{Nat}$. A fresh variable is a variable that appears nowhere else. $T_\Sigma(\mathcal{X})$ is the set of terms of sort $s$, and $T_{\Sigma, s}$ is the set of ground terms of sort $s$. We write $T_{\Sigma, s}$ for the corresponding term algebras. For a term $t$, we write $\text{Var}(t)$ for the set of all variables in $t$. We assume that $T_{\Sigma, s} \neq \emptyset$ for every sort $s$.

The set of positions of a term $t$, written $\text{Pos}(t)$, is represented as a sequence of natural numbers, e.g. $1.2.1$. The set of non-variable positions is written $\text{Pos}_{\Sigma}(t)$. The root position of a term is $\lambda$. The subterm of a position $t$ at position $p$ is $t[p]$ and $t[u]_p$ is the term $t$ where $t[p]$ is replaced by $u$. By $\text{root}(t)$ we denote the symbol occurring at the root position of $t$.

A substitution $\sigma$ is a mapping from a finite subset of $\mathcal{X}$, written $\text{Dom}(\sigma)$, to $T_\Sigma(\mathcal{X})$. The set of variables introduced by $\sigma$ is $\text{Ran}(\sigma)$. The identity substitution is $\text{id}$. Substitutions are homomorphically extended to $T_\Sigma(\mathcal{X})$. The application of a substitution $\sigma$ to a term $t$ is denoted by $t\sigma$. The restriction of $\sigma$ to a set of variables $V$ is $\sigma|_V$. Composition of two substitutions is denoted by juxtaposition, i.e., $\sigma \sigma'(X) = \sigma'(\sigma(X))$ for any variable $X$. We call a substitution $\sigma$ a renaming if there is another substitution $\sigma^{-1}$ such that $(\sigma\sigma^{-1})|_{\text{Dom}(\sigma)} = \text{id}$. Substitutions are sort-preserving, i.e., for any substitution $\sigma$, if $X \in X_s$, then $X\sigma \in T_{\Sigma}(X)_s$. We assume substitutions are idempotent, i.e., $\sigma(X) = \sigma(\sigma(X))$. 

9
for any variable $X$.

A $\Sigma$-equation is an unoriented pair $t = t'$. An *equational theory* $(\Sigma, E)$ is a set of $\Sigma$-equations. An equational theory $(\Sigma, E)$ is *regular* if for each $t = t' \in E$, we have $\text{Var}(t) = \text{Var}(t')$. Given $\Sigma$ and a set $E$ of $\Sigma$-equations, order-sorted equational logic induces a congruence relation $=_E$ on terms $t, t' \in T_\Sigma(\mathcal{X})$, see (Goguen and Meseguer 1992; Meseguer 1997).

The $E$-subsumption preorder $\leq_E$ (simply $\leq$ when $E$ is empty) holds between $t, t' \in T_\Sigma(\mathcal{X})$, denoted $t \leq_E t'$ (meaning that $t$ is more general than $t'$ modulo $E$), if there is a substitution $\sigma$ such that $t\sigma =_E t'$. Such a substitution $\sigma$ is said to be an $E$-matcher for $t'$ in $t$. The $E$-renaming equivalence $t \simeq_E t'$ (or $\simeq$ if $E$ is empty), holds if there is a renaming $\theta$ such that $t\theta =_E t'$. We write $t <_E t'$ (or $<_E$ if $E$ is empty) if $t \leq_E t'$ and $t \not\simeq_E t'$.

3. Syntactic Least General Generalization

In order to better present our work, in this section we revisit untyped generalization (Huet 1976; Plotkin 1970; Reynolds 1970) and formalize the lgg computation by means of a new inference system that will be useful in our subsequent extension of this algorithm to the order-sorted setting given in Section 4 and to the equational setting given in Section 5. Throughout this section, we assume unsorted terms, i.e., $t \in T_\Sigma(\mathcal{X})$, with an unsorted signature $\Sigma$. This can be understood as the special case of having only one sort.

Most general unification of a (unifiable) set $M$ of terms is the least upper bound (most general instance, mgi) of $M$ under the standard instantiation quasi-ordering $\leq$ on terms given by the relation of being “more general” (i.e., $s$ is an instance of $t$, written $t \leq s$, iff there exists $\theta$ such that $t\theta = s$). Formally,

$$\text{instances}(M) = \{t' \in T_\Sigma(\mathcal{X}) \mid \forall t \in M, \ t \leq t'\}$$

and

$$\text{mgi}(M) = s \in \text{instances}(M) \text{ s.t. } \forall t' \in \text{instances}(M), s \leq t'.$$

Least general generalization, lgg, of $M$ corresponds to the greatest lower bound, i.e.,

$$\text{generalizations}(M) = \{t' \in T_\Sigma(\mathcal{X}) \mid \forall t \in M, \ t' \leq t\}$$

and

$$\text{lgg}(M) = s \in \text{generalizations}(M) \text{ s.t. } \forall t' \in \text{generalizations}(M), t' \leq s.$$
Central to this algorithm is the global function $\Phi$ that is used to guarantee that the same disagreements are replaced by the same variable in both terms. Different choices of $\Phi$ may result in different generalizations that are equivalent up to variable renaming.

In the following, we provide a novel set of inference rules for computing the (syntactic) least generalization of two terms, first proposed in (Alpuente et al., 2009b), that uses a local store of already solved generalization sub-problems. The advantage of using such a store is that, differently from the global repository $\Phi$, our stores are local to the computation traces. This non–globality of the stores is the key for effectively computing a complete and minimal set of least general generalizations in both, the order–sorted extension and the equational generalization algorithm developed in this work. A different formulation by means of inference rules is given in (Pottier, 1989), where the store is not explicit in the configurations but is implicitly kept within the constraint and substitution components, which is less intuitive and causes the accumulation of a lot of bindings for many variables with the same instantiations.

In our formulation, we represent a generalization problem between terms $s$ and $t$ as a constraint $s \triangleq t$, where $x$ is a fresh variable that stands for a tentative generalization of $s$ and $t$. By means of this representation, any generalization $w$ of $s$ and $t$ is given by a suitable substitution $\theta$ such that $x\theta = w$.

We compute the least general generalization of $s$ and $t$, written $\text{lgg}(s, t)$, by means of a transition system $(\text{Conf}, \rightarrow)$ (Plotkin, 2004) where $\text{Conf}$ is a set of configurations and the transition relation $\rightarrow$ is given by a set of inference rules. Besides the constraint component, i.e., a set of constraints of the form $t_i \triangleq t'_i$, and the substitution component, i.e., the partial substitution computed so far, configurations also include the extra constraint component that we call the store.

**Definition 1.** A configuration $\langle \text{CT} \mid S \mid \theta \rangle$ consists of three components: (i) the constraint component $\text{CT}$, i.e., a conjunction $s_1 \triangleq t_1 \land \ldots \land s_n \triangleq t_n$ that represents the set of unsolved constraints, (ii) the store component $S$, that records the set of already solved constraints, and (iii) the substitution component $\theta$, that consists of bindings for some variables previously met during the computation.

Starting from the initial configuration $\langle t \triangleq t' \mid \emptyset \mid \text{id} \rangle$, configurations are transformed until a terminal configuration of the form $\{ \emptyset \mid S \mid \theta \}$, i.e., a normal form w.r.t. the inference system, is reached. Then, the lgg of $t$ and $t'$ is given by $x\theta$. As we shall see, $\theta$ is unique up to renaming. Given a constraint $t \triangleq t'$, we call $x$ an index variable or a variable at the index position of the constraint. Given a set $C$ of constraints, each of the form $t \triangleq t'$ for some $t$, $t'$, and $x$, we define the set of index variables as $\text{Index}(C) = \{ y \in \mathcal{X} \mid \exists u \triangleq v \in C \}$.

The transition relation $\rightarrow$ is given by the smallest relation satisfying the rules in Figure 1. In this paper, variables of terms $t$ and $t'$ in a generalization problem
Decompose \[ f \in (\Sigma \cup \mathcal{X}) \]
\[ \langle f(t_1, \ldots, t_n) \xrightarrow{x} f(t'_1, \ldots, t'_n) \land CT \mid S \mid \theta \rangle \rightarrow \langle t_1 \xrightarrow{x} t'_1 \land \ldots \land t_n \xrightarrow{x} t'_n \land CT \mid S \mid \theta \sigma \rangle \]
where \( \sigma = \{ x \mapsto f(x_1, \ldots, x_n) \} \), \( x_1, \ldots, x_n \) are fresh variables, and \( n \geq 0 \).

Solve \[ \text{root}(t) \neq \text{root}(t') \land \exists y : t \xrightarrow{y} t' \in S \]
\[ \langle t \xrightarrow{y} t' \land CT \mid S \mid \theta \rangle \rightarrow \langle CT \mid S \land t \xrightarrow{y} t' \mid \theta \rangle \]

Recover \[ \text{root}(t) \neq \text{root}(t') \]
\[ \langle t \xrightarrow{y} t' \land CT \mid S \land t \xrightarrow{y} t' \mid \theta \sigma \rangle \rightarrow \langle CT \mid S \land t \xrightarrow{y} t' \mid \theta \sigma \rangle \]
where \( \sigma = \{ x \mapsto y \} \).

Figure 1: Rules for least general generalization

\( t \xrightarrow{y} t' \) are considered as constants, and are never instantiated. The meaning of the rules is as follows.

- The rule Decompose is the syntactic decomposition generating new constraints to be solved.
- The rule Solve checks that a constraint \( t \xrightarrow{y} t' \in CT \) with \( \text{root}(t) \neq \text{root}(s) \), is not already solved. If not already there, the solved constraint \( t \xrightarrow{y} t' \) is added to the store \( S \).
- The rule Recover checks if a constraint \( t \xrightarrow{y} t' \in CT \) with \( \text{root}(t) \neq \text{root}(t') \), is already solved, i.e., if there is already a constraint \( t \xrightarrow{y} t' \in S \) for the same pair of terms \( (t, t') \) with variable \( y \). This is needed when the input terms of the generalization problem contain the same generalization subproblems more than once, e.g., the lgg of \( f(f(f(a, a), a), b) \) and \( f(f(f(b, b), a), b) \) is \( f(f(f(y, y), a), b) \).

Example 1. Consider the terms \( t = f(g(a), g(y), a) \) and \( t' = f(g(b), g(y), b) \). In order to compute the least general generalization of \( t \) and \( t' \), we apply the inference rules of Figure 1. The substitution component in the final configuration obtained by the lgg algorithm is \( \theta = \{ x_1 \mapsto f(g(x_4), g(y), x_4), x_2 \mapsto g(x_1), x_3 \mapsto g(y), x_4 \mapsto y \} \), hence the computed lgg is \( x_\theta = f(g(x_4), g(y), x_4) \). The execution trace is showed in Figure 2. Note that variable \( x_4 \) is repeated, to ensure that the least general generalization is obtained.

3.1. Termination and Confluence of the untyped, syntactic least general generalization algorithm

Termination of the transition system \((\text{Conf}, \rightarrow)\) is straightforward.
Theorem 1 (Termination). Every derivation stemming from an initial configuration \( \langle t \vdash t' \mid \emptyset \mid id \rangle \) using the inference rules of Figure 1 terminates with a configuration \( \langle \emptyset \mid S \mid \theta \rangle \).

Proof. Let \(|u|\) be the number of symbol occurrences in the syntactic object \( u \). Since the minimum of \(|t|\) and \(|t'|\) is an upper bound to the number of times that the inference rule Decompose of Figure 1 can be applied, and the application of rules Solve and Recover strictly decreases the size \(|CT|\) of the CT component of the lgg configurations at each step, then any derivation necessarily terminates.

Note that the inference rules of Figure 1 are non-deterministic (i.e., they depend on the chosen constraint of the set \( CT \)). However, in the following we show that they are confluent up to variable renaming (i.e., the chosen transition is irrelevant for computation of terminal configurations). This justifies the well-known fact that the least general generalization of two terms is unique up to variable renaming (Lassez et al. 1988). In order to prove the confluence up to renaming of the calculus, let us first demonstrate an auxiliary result stating that only (independently) fresh variables \( y \) appear in the index positions of the constraints in \( CT \) and \( S \) components of lgg configurations.

Lemma 1 (Uniqueness of Generalization Variables). Let \( t, t' \in T_\Sigma(\mathcal{X}) \) and \( x \in \mathcal{X} \). For every derivation \( \langle t \vdash t' \mid \emptyset \mid id \rangle \rightarrow^* \langle CT \mid S \mid \theta \rangle \) stemming from the initial configuration \( \langle t \vdash t' \mid \emptyset \mid id \rangle \) using the inference rules of Figure 1 and for every \( u \vdash v \in CT \) (similarly \( u \vdash v \in S \)), the variable \( y \) does not appear in any other constraint in \( CT \) or \( S \), i.e., there are no \( u', v' \in T_\Sigma(\mathcal{X}) \) such that \( u' \vdash v' \in CT \) or \( u' \vdash v' \in S \).
Proof. By induction on the length \( n \) of the sequence \( \langle t \dashv t' \mid \emptyset \mid \text{id} \rangle \to^n \langle CT \mid S \mid \theta \rangle \). If \( n = 0 \), then the conclusion follows, since \( CT = t \dashv t' \) and \( S = \emptyset \).

If \( n > 0 \), then we split the derivation into \( \langle t \dashv t' \mid \emptyset \mid \text{id} \rangle \to^{n-1} \langle CT' \mid S' \mid \theta' \rangle \to \langle CT \mid S \mid \theta \rangle \) and we consider each inference rule of Figure 1 separately:

- **Decompose.** Here \( CT' = f(t_1, \ldots, t_n) \dashv f(t_1', \ldots, t_n') \land CT'', \ S = S' \), \( CT = t_1 \dashv t_1' \land \ldots \land t_n \dashv t_n' \land CT'' \), and \( \theta = \theta' \sigma \) where \( \sigma = \{ x \mapsto f(x_1, \ldots, x_n) \} \), \( x_1, \ldots, x_n \) are fresh variables, and \( n \geq 0 \). By induction hypothesis, \( x \) does not appear in \( CT'' \) and \( S' \). Thus, it follows that \( x_1, \ldots, x_n \) do not appear in \( CT \) and \( S \).

- **Solve.** Here \( CT' = t \dashv t' \land CT'', \ S = S' \), \( \theta = \theta' \), and the conclusion follows by induction hypothesis, since \( x \) does not appear in \( CT' \) and \( S' \).

- **Recover.** Here \( CT' = t \dashv t' \land CT'', \ S = S' \), \( \theta = \theta' \sigma \), \( \sigma = \{ x \mapsto y \} \), and the conclusion follows by induction hypothesis, since both \( x \) and \( y \) do not appear in \( CT' \) and \( S' \).

Now we are ready to demonstrate the confluence of the lgg computations.

Theorem 2 (Confluence). The set of derivations stemming from any initial configuration \( \langle t \dashv t' \mid \emptyset \mid \text{id} \rangle \) using the inference rules of Figure 1 contain a unique solution \( \langle \emptyset \mid S \mid \theta \rangle \) up to renaming.

Proof. Given a configuration \( \langle t \dashv t' \mid CT \mid S \mid \theta \rangle \), there is only one possible transition step applicable to \( t \dashv t' \) thanks to the non-overlapping inference rules of Figure 1. Thus, we must consider the case of having two constraints with the corresponding transitions.

Given any configuration \( \langle t_1 \dashv t_2 \land t_1' \dashv t_2' \land CT \mid S \mid \theta \rangle \) stemming from the initial configuration \( \langle t \dashv t' \mid \emptyset \mid \text{id} \rangle \), we analyse each possible inference rule application to both \( t_1 \dashv t_2 \) and \( t_1' \dashv t_2' \). We underline the relation \( \to \) with the name of the inference rule used for transformation.

- If Decompose is applied to at least one of \( t_1 \dashv t_2 \) and \( t_1' \dashv t_2' \), then there is no interaction between the constraints, since the Decompose rule is not recording information in the store \( S \), and the conclusion follows from the uniqueness of index variables (Lemma 1). That is, given two inference steps
  \[
  \langle t_1 \dashv t_2 \land t_1' \dashv t_2' \land CT \mid S \mid \theta \rangle \to \langle t_1' \dashv t_2' \land CT \mid S_1 \mid \theta_1 \rangle
  \]
and
\[ \langle t_1 \overset{y}{=} t_2 \land t_1' \overset{y'}{=} t_2' \land CT \mid S \mid \theta \rangle \rightarrow \langle t_1 \overset{y}{=} t_2 \land CT \mid S_2 \mid \theta_2 \rangle, \]
then there are two configurations \( \langle CT_{12} \mid S_{12} \mid \theta_{12} \rangle \) and \( \langle CT_{21} \mid S_{21} \mid \theta_{21} \rangle \) such that
\[ \langle t_1 \overset{y'}{=} t_2 \land CT_1 \mid S_1 \mid \theta_1 \rangle \rightarrow \langle CT_{12} \mid S_{12} \mid \theta_{12} \rangle, \]
\[ \langle t_1 \overset{y}{=} t_2 \land CT_2 \mid S_2 \mid \theta_2 \rangle \rightarrow \langle CT_{21} \mid S_{21} \mid \theta_{21} \rangle, \]
and \( \langle CT_{12} \mid S_{12} \mid \theta_{12} \rangle \simeq \langle CT_{21} \mid S_{21} \mid \theta_{21} \rangle \). That is, there is a renaming substitution between both configurations thanks to the uniqueness of added index variables.

- If Recover is applied to at least one of \( t_1 \overset{y}{=} t_2 \) and \( t_1' \overset{y'}{=} t_2' \), we have the same conclusion, since the Recover rule is not recording information in the store \( S \).

- If \( t_1 = t_1' \) and \( t_2 = t_2' \), then the application of the inference rule Solve to \( t_1 \overset{y}{=} t_2 \) disables the application of the inference rule Solve to \( t_1' \overset{y'}{=} t_2' \) but enables the application of the inference rule Recover to \( t_1' \overset{y'}{=} t_2' \). That is, given the two inference steps
\[ \langle t_1 \overset{y}{=} t_2 \land t_1 \overset{y'}{=} t_2 \land CT \mid S \mid \theta \rangle \rightarrow_{\text{Solve}} \langle t_1 \overset{y}{=} t_2 \land CT \mid S \land t_1 \overset{y}{=} t_2 \mid \theta \rangle \]
and
\[ \langle t_1 \overset{y}{=} t_2 \land t_1 \overset{y'}{=} t_2 \land CT \mid S \mid \theta \rangle \rightarrow_{\text{Solve}} \langle t_1 \overset{y}{=} t_2 \land CT \mid S \land t_1 \overset{y'}{=} t_2 \mid \theta \rangle, \]
we have that
\[ \langle t_1 \overset{y'}{=} t_2 \land CT \mid S \land t_1 \overset{y}{=} t_2 \mid \theta \rangle \rightarrow_{\text{Recover}} \langle CT \mid S \land t_1 \overset{y}{=} t_2 \mid \theta \rangle \]
and
\[ \langle t_1 \overset{y'}{=} t_2 \land CT \mid S \land t_1 \overset{y}{=} t_2 \mid \theta \rangle \rightarrow_{\text{Recover}} \langle CT \mid S \land t_1 \overset{y'}{=} t_2 \mid \theta \rangle. \]
Thus, \( \langle CT \mid S \land t_1 \overset{y}{=} t_2 \mid \theta \rangle \simeq \langle CT \mid S \land t_1 \overset{y'}{=} t_2 \mid \theta \rangle \) and the conclusion follows.

3.2. Correctness and Completeness

Before proving correctness and completeness of the above inference rules, we introduce the auxiliary concepts of a conflict position and of conflict pairs, and
three auxiliary lemmas. Also, note that for a given constraint $t \hat{=} t'$, the variable $x$ is a valid generalization of $t$ and $t'$, though generally not the least one.

The first lemma states that the range of the substitutions partially computed at any stage of a generalization derivation coincides with the set of the index variables of the configuration.

**Lemma 2.** Given terms $t$ and $t'$ and a fresh variable $x$ such that $\langle t \hat{=} t' \mid \emptyset \mid id \rangle \rightarrow^* \langle CT \mid S \mid \theta \rangle$ using the inference rules of Figure 1, then $\text{Index}(S \cup CT) \subseteq \text{Ran}(\theta)$, and $\text{Ran}(\theta) = \text{Var}(x\theta)$.

**Proof.** Immediate by construction. \hfill \Box

The following lemma establishes an auxiliary property that is useful for defining the notion of a conflict pair of terms.

**Lemma 3.** Given terms $t$ and $t'$ and a fresh variable $x$, $\langle t \hat{=} t' \mid \emptyset \mid id \rangle \rightarrow^* \langle u \hat{=} v \wedge CT \mid S \mid \theta \rangle$ using the inference rules of Figure 1, if there exists a position $p$ of $t$ and $t'$ such that $t|_p = u$, $t'|_p = v$, and $\forall p' < p$, $\text{root}(t|_{p'}) = \text{root}(t'|_{p'})$.

**Proof.** Straightforward by successive application of the inference rule Decompose of Figure 1. \hfill \Box

The notion of a conflict pair is the key idea for our generalization proof schema.

**Definition 2 (Conflict Position/Pair).** Given terms $t$ and $t'$, a position $p \in \text{Pos}(t) \cap \text{Pos}(t')$ is called a conflict position of $t$ and $t'$ if $\text{root}(t|_p) \neq \text{root}(t'|_p)$ and for all $q < p$, $\text{root}(t|_q) = \text{root}(t'|_q)$. Given terms $t$ and $t'$, the pair $(u, v)$ is called a conflict pair of $t$ and $t'$ if there exists at least one conflict position $p$ of $t$ and $t'$ such that $u = t|_p$ and $v = t'|_p$.

The following lemma states the appropriate connection between the constraints in a derivation and the conflict pairs of the initial configuration.

**Lemma 4.** Given terms $t$ and $t'$ and a fresh variable $x$, $\langle t \hat{=} t' \mid \emptyset \mid id \rangle \rightarrow^* \langle \langle CT \mid u \hat{=} v \wedge S \mid \theta \rangle \rangle$ using the inference rules of Figure 1, if there exists a conflict position $p$ of $t$ and $t'$ such that $t|_p = u$ and $t'|_p = v$.

**Proof.** ($\Rightarrow$) If $u \hat{=} v \in S$, then there must be two configurations $\langle u \hat{=} v \wedge CT_1 \mid S_1 \mid \theta_1 \rangle$, $\langle CT_2 \mid u \hat{=} v \wedge S_2 \mid \theta_2 \rangle$ such that

$$\langle t \hat{=} t' \mid \emptyset \mid id \rangle \rightarrow^* \langle u \hat{=} v \wedge CT_1 \mid S_1 \mid \theta_1 \rangle \rightarrow \langle CT_2 \mid u \hat{=} v \wedge S_2 \mid \theta_2 \rangle \rightarrow^* \langle \emptyset \mid S \mid \theta \rangle,$$

$u \hat{=} v \notin S_1$, $u \hat{=} v \notin CT_2$, and $\text{root}(u) \neq \text{root}(v)$. By Lemma 3, there exists a position $p$ of $t$ and $t'$ such that $t|_p = u$ and $t'|_p = v$. Since $\text{root}(u) \neq \text{root}(v)$, $p$ is a conflict position.
(⇐) By Lemma \[3\], there is a configuration \(\langle u \triangleq v \land CT_1 \mid S_1 \mid \theta_1 \rangle\) such that 
\(\langle t \triangleq t' \mid \emptyset \mid id \rangle \rightarrow^* \langle u \triangleq v \land CT_1 \mid S_1 \mid \theta_1 \rangle\), \(u \triangleq v \notin S_1\), and \(\text{root}(u) \neq \text{root}(v)\).

Then, the inference rule Solve is applied, i.e., \(\langle u \triangleq v \land CT_1 \mid S_1 \mid \theta_1 \rangle \rightarrow (CT_1 \mid u \triangleq v \land S_1 \mid \theta_1)\), and the constraint \(u \triangleq v\) will be part of \(S\) in the final configuration \(\langle \emptyset \mid S \mid \theta \rangle\).

\(\square\)

The following lemma establishes the link between the substitution component of a terminal configuration (simply called “computed substitution” from now on) and a proper generalization term.

**Lemma 5.** Given terms \(t\) and \(t'\) and a fresh variable \(x\), \(\langle x \triangleq t' \mid \emptyset \mid id \rangle \rightarrow^* \langle C \mid S \mid \theta \rangle\) using the inference rules of Figure 2 iff \(x\theta\) is a generalization of \(t\) and \(t'\).

**Proof.** By structural induction on the term \(x\theta\). If \(x\theta = x\), then \(\theta = id\) and the conclusion follows. If \(x\theta = f(u_1, \ldots, u_k)\), then the Decompose inference rule is applied and we have that \(t = f(t_1, \ldots, t_k)\) and \(t' = f(t'_1, \ldots, t'_k)\). By induction hypothesis, \(u_i\) is a generalization of \(t_i\) and \(t'_i\), for each \(i\). Now, if there is no variable shared between two different \(u_i\), then the conclusion follows.

Otherwise, for each variable \(z\) shared between two different terms \(u_i\) and \(u_j\), there is a constraint \(u_1 \triangleq u_2 \in S\) and, by Lemma 4, there are conflict positions \(p_i\) in \(t_i\) and \(t'_i\), and \(p_j\) in \(t_j\) and \(t'_j\) such that \(t_i|_{p_i} = t_j|_{p_j}\) and \(t'_i|_{p_i} = t'_j|_{p_j}\). Thus, the conclusion follows.

\(\square\)

Finally, correctness and completeness are proved as follows.

**Theorem 3 (Correctness and Completeness).** Given terms \(t\) and \(t'\) and a fresh variable \(x\), \(u\) is the lgg of \(t\) and \(t'\) iff \(\langle x \triangleq t' \mid \emptyset \mid id \rangle \rightarrow^* (\emptyset \mid S \mid \theta)\) using the inference rules of Figure 1 and \(u \simeq x\theta\).

**Proof.** We rely on the already known existence and uniqueness of the lgg of \(t\) and \(t'\) [Lassez et al., 1988] and reason by contradiction. Consider the normalizing derivation \(\langle t \triangleq t' \mid \emptyset \mid id \rangle \rightarrow^* (\emptyset \mid S \mid \theta)\). By Lemma 5, \(x\theta\) is a generalization of \(t\) and \(t'\). If \(x\theta\) is not the lgg of \(t\) and \(t'\) up to renaming, then there is a term \(u\) which is the lgg of \(t\) and \(t'\) and a substitution \(\rho\) which is not a variable renaming such that \(x\theta\rho = u\). By Lemma 2, \(\text{Ran}(\theta) = \text{Var}(x\theta)\), hence we can choose \(\rho\) with \(\text{Dom}(\rho) = \text{Var}(x\theta)\). Now, since \(\rho\) is not a variable renaming, either:

1. there are variables \(y, y' \in \text{Var}(x\theta)\) and a variable \(z\) such that \(y\rho = y'\rho = z\), or
2. there is a variable \(y \in \text{Var}(x\theta)\) and a non-variable term \(v\) such that \(y\rho = v\).

In case (1), there are two conflict positions \(p, p'\) for \(t\) and \(t'\) such that \(u|_{p} = z = u_{p'}\) and \(x\theta|_{p} = y\) and \(x\theta|_{p'} = y'.\) In particular, this means that \(t|_{p} = t|_{p'}\) and \(t'|_{p} = t'|_{p'}\). But this is impossible by Lemmas 4 and 2. In case (2), there is a
Decompose

\[ f \in (\Sigma \cup \mathcal{A}) \land f : [s_1] \times \ldots \times [s_n] \rightarrow [s] \]
\[ \langle f(t_1, \ldots, t_n) \rangle \triangleq f(s_1, \ldots, s_n) \land C \mid S \mid \theta \rangle \rightarrow \\
\langle t_1 \rangle_{[s_1]} \triangleq s_1 \land \ldots \land \langle t_n \rangle_{[s_n]} \triangleq s_n \land C \mid S \mid \theta\sigma \rangle \]

where \( \sigma = \{x : [s] \mapsto f(x_1 : [s_1], \ldots, x_n : [s_n])\} \), \( x_1 : [s_1], \ldots, x_n : [s_n] \) are fresh variables, and \( n \geq 0 \)

Solve

\[ \text{root}(t) \neq \text{root}(t') \land s' \in \text{LUBS}(LS(t), LS(t')) \land \exists y \exists z : s'' : \langle y : s' \rangle \\
\langle t \triangleq t' \land C \mid S \mid \theta \rangle \rightarrow \langle C \mid S \land t \triangleq t' \mid \theta\sigma \rangle \]

where \( \sigma = \{x : [s] \mapsto z : s'\} \) and \( z : s' \) is a fresh variable.

Recover

\[ \text{root}(t) \neq \text{root}(t') \]
\[ \langle t \triangleq t' \land C \mid S \land t \triangleq t' \mid \theta \rangle \rightarrow \langle C \mid S \land t \triangleq t' \mid \theta\sigma \rangle \]

where \( \sigma = \{x : [s] \mapsto y : s'\} \)

Figure 3: Rules for order-sorted least general generalization.

Let us mention that the generalization algorithm can also be used to compute (thanks to associativity and commutativity of symbol \( \land \)) the lgg of an arbitrary set of terms by successively computing the lgg of two elements of the set in the obvious way.

4. Order-sorted Least General Generalization

In this section, we generalize the unsorted generalization algorithm presented in Section 3 to the order-sorted setting.

We consider two terms \( t \) and \( t' \) having the same top sort, i.e., \( [LS(t)] = [LS(t')] \). Otherwise they are incomparable and no generalization exists. Starting from the initial configuration \( \langle t \triangleq t' \mid \emptyset \mid \text{id} \rangle \) where \( [s] = [LS(t)] = [LS(t')] \), configurations are transformed until a terminal configuration \( \langle \emptyset \mid S \mid \theta \rangle \) is reached. In the order-sorted setting, the lgg, in general, is not unique. Each terminal configuration \( \langle \emptyset \mid S \mid \theta \rangle \) provides an lgg of \( t \) and \( t' \) given by \( (x : [s])\theta \). A substitution \( \delta \) is called downgrading if each binding is of the form \( x : [s] \mapsto x' : s' \), where \( x \) and \( x' \) are variables and \( s' \leq s \).

The transition relation \( \rightarrow \) is given by the smallest relation satisfying the rules in Figure 3. The meaning of these rules is as follows.
\[ \text{lgg}(f(x:A), f(y:B)) \]
\[ \downarrow \] Initial Configuration
\[ \langle f(x:A) \triangleq f(y:B) \mid \emptyset \mid \text{id} \rangle \]
\[ \downarrow \] Decompose
\[ \langle x:A \triangleq y:B \mid \emptyset \mid \{ z:E \mapsto f(z_1:E) \} \rangle \]
\[ \text{Solve} \]
\[ \langle \emptyset \mid x:A \triangleq y:B \mid \{ z:E \mapsto f(z_2:C), z_1:E \mapsto z_2:C \} \rangle \]
\[ \langle \emptyset \mid x:A \triangleq y:B \mid \{ z:E \mapsto f(z_3:D), z_1:E \mapsto z_3:D \} \rangle \]

Figure 4: Computation trace for order–sorted generalization of terms \( f(x) \) and \( f(y) \)

\[ \text{Example 2.} \] Let \( t = f(x:A) \) and \( t' = f(y:B) \) be two terms where \( x \) and \( y \) are variables of sorts \( A \) and \( B \), respectively, and assume the sort hierarchy that is shown in Figure 5. The typed definition of \( f \) is \( f : E \to E \). Starting from the initial configuration \( \langle f(x:A) \triangleq f(y:B) \mid \emptyset \mid \text{id} \rangle \), we apply the inference rules of Figure 3 and the substitutions obtained by the lgg algorithm are \( \theta_1 = \{ z:E \mapsto \}

• The rule **Decompose** is the syntactic decomposition generating new constraints to be solved. Fresh variables are initially assigned a top sort, which will be appropriately “downgraded” when necessary.

• The rule **Recover** reuses a previously solved constraint, similarly to to the corresponding unsorted rule of Figure 1.

• The rule **Solve** checks that a constraint \( t \triangleq t' \in C \), with \( \text{root}(s) \neq \text{root}(t) \), is not already solved. Then the solved constraint \( t \triangleq t' \) is added to the store \( S \), and the substitution \( \{ x \mapsto z \} \) is composed with the substitution part, where \( z \) is a fresh variable with sort in the \textit{LUBS} of the least sorts of both terms. Note that this is the only additional source of non-determinism (besides the choice of the constraint to work on) in our inference rules, in contrast to Figure 1. This extra non–determinism causes our rules to be non–confluent in general. However, this is essential for our algorithm to work, since different final configurations \( \langle \emptyset \mid S_1 \mid \theta_1 \rangle, \ldots, \langle \emptyset \mid S_n \mid \theta_n \rangle \) correspond to different (least general) generalizations \( x\theta_1, \ldots, x\theta_n \).

**Figure 5: Sort hierarchy**
\[ f(z_2: C), z_1: E \mapsto z_2: C \] and \( \theta_2 = \{ z_1: E \mapsto f(z_3: D), z_1: E \mapsto z_3: D \} \). Note that \( \theta_1 \) and \( \theta_2 \) are incomparable, so that we have two possible lgs where \((z: E) \theta_1 = f(z_2: C)\) and \((z: E) \theta_2 = f(z_3: D)\). The computation of both solutions is illustrated in Figure 4.

4.1. Termination and Confluence

Termination of the transition system \((\text{Conf}, \rightarrow)\) is straightforward.

**Theorem 4 (Termination).** Every derivation stemming from an initial configuration \( (t \mapsto t' \mid \emptyset \mid \text{id}) \) using the inference rules of Figure 3 where \( s = [\text{LS}(t)] = [\text{LS}(t')] \) terminates with a configuration \( (\emptyset \mid S \mid \theta) \).

**Proof.** Similar to the proof of Theorem 1. \( \square \)

The transition system \((\text{Conf}, \rightarrow)\) is no longer confluent, as shown in Example 2. However, confluence can be recovered under appropriate conditions.

**Definition 3 (Top-sorted Constant).** Given an order-sorted signature \( \Sigma \), we say that a constant \( c : \text{nil} \rightarrow s \) is top-sorted if \( s = [s] \).

**Definition 4 (Top-sorted Variable).** A variable \( x : s \) is called top-sorted if \( s = [s] \).

**Definition 5 (Top-sorted Term).** A term \( t \) is called top-sorted if every variable and every constant in \( t \) are top-sorted.

The following result uses the assumption of a kind-completed order-sorted signature described in Section 2.

**Lemma 6.** Given a top-sorted term \( t \), \( \text{LS}(t) = [\text{LS}(t)] \).

**Proof.** By structural induction on \( t \). The cases when \( t \) is a variable or a constant are straightforward. If \( t = f(t_1, \ldots, t_n) \), then by induction hypothesis, \( \text{LS}(t_1) = [\text{LS}(t_1)], \ldots, \text{LS}(t_n) = [\text{LS}(t_n)] \), and given that \( f : [s_1] \times \cdots \times [s_n] \rightarrow [s] \), we have that \( \text{LS}(t) = [\text{LS}(t)] \). \( \square \)

**Lemma 7.** Given two top-sorted terms \( t, t' \), \( \text{LUBS}(\text{LS}(t), \text{LS}(t')) = \text{LS}(t) = \text{LS}(t') = [\text{LS}(t)] = [\text{LS}(t')] \).

**Proof.** By Lemma 6, \( \text{LS}(t) = [\text{LS}(t)] \) and \( \text{LS}(t') = [\text{LS}(t')] \) and, since \([\text{LS}(t)]\) is the top sort in the connected component, we conclude that \( \text{LUBS}(\text{LS}(t), \text{LS}(t')) = [\text{LS}(t)] = [\text{LS}(t')] \). \( \square \)

**Theorem 5 (Confluence).** The set of derivations stemming from an initial configuration \( (t \mapsto t' \mid \emptyset \mid \text{id}) \) using the inference rules of Figure 3 where \( t \) and \( t' \) are top-sorted terms and \( s = [\text{LS}(t)] = [\text{LS}(t')] \), contain a unique solution \( (\emptyset \mid S \mid \theta) \) up to renaming.

**Proof.** Similar to the proof of Theorem 2, but taking into account that Lemma 7 ensures that there is no non-determinism involved in the application of the inference rule Solve. \( \square \)
4.2. Order-sorted lgg computation by subsort specialization

Even if the set of least general generalizations of two terms is not generally a singleton, there is still a unique top-sorted generalization that can just be specialized into the appropriate subsorts. This enables a different approach to computing order-sorted least general generalizations by just removing sorts (i.e., upgrading variables to top sorts) in order to compute (unsorted) lgg’s, and then obtaining the right subsorts by a suitable post-processing. Obviously, the set of inference rules of Figure 3 has a better performance than this alternative method of first upgrading variables, computing the standard lgg’s, and then downgrading variables, since the inference rules of Figure 3 detect sort-based failures much earlier. Indeed, we do not use this approach in practice, but we only use it for the proofs of correctness and completeness of the inference rules given in Section 4.3 below. Note that this proof schema for correctness and completeness of inference rules is useful here for the order-sorted generalization and also for the order-sorted E-generalization of Section 6 below.

To simplify our notation, in the following we write \( t[u_1, \ldots, u_n] \) instead of \( ((t[u_1]) \cdots)[u_1, \ldots, u_n] \). The notion of conflict pair of Definition 2 can be extended to the order-sorted case in the obvious way, since two variables of different sorts having the same name, e.g. \( x_1 : s_1 \) and \( x_2 : s_2 \), are considered to be different.

**Definition 6 (Top-sorted Generalization).** Given terms \( t \) and \( t' \) such that \( LS(t) = LS(t') \), let \( (u_1, v_1), \ldots, (u_k, v_k) \) be the conflict pairs of \( t \) and \( t' \), and for each such conflict pair \( (u_i, v_i) \), let \( p_i^1, \ldots, p_i^{n_i} \) be the corresponding conflict positions (i.e., \( t[p_i^j] = u_i \) and \( t'[p_i^j] = v_i \) for \( 1 \leq j \leq n_i \)), and let \( s_i = LS(u_i) \) and \( s_i = LS(v_i) \). The top-sorted generalization of \( t \) and \( t' \) is defined by

\[
tsg(t, t') = ((t[x_1 : s_1, \ldots, p_1^{n_1}], \ldots, x_k : s_k, \ldots, p_k^{n_k})
\]

where \( x_1 : s_1, \ldots, x_k : s_k \) are fresh variables.

**Example 3.** Let us consider the terms \( t = f(x:A) \) and \( t' = f(y:B) \) of Example 2. We have that \( tsg(t, t') = f(z:E) \), since there is only one conflict pair \( (x:A, y:B) \) and \( |A| = |B| = E \).

Once the unique top-sorted lgg is generated, the order-sorted lgg’s are obtained by subsort specialization.

**Definition 7 (Sort-specialized Generalization).** Given terms \( t \) and \( t' \) such that \( LS(t) = LS(t') \), let \( (u_1, v_1), \ldots, (u_k, v_k) \) be the conflict pairs of \( t \) and \( t' \). We define

\[
sort-down-subs(t, t') = \{ \rho \mid Dom(\rho) = \{ x_1 : s_1, \ldots, x_k : s_k \} \land \forall 1 \leq i \leq k, \rho(x_i : s_i) = x_i : s'_i \land s'_i \in LUBS(LS(u_i), LS(v_i)) \}
\]

where all the \( x_i : s'_i \) are fresh variables. The set of sort-specialized generalizations of \( t \) and \( t' \) is defined as \( ssg(t, t') = \{ tsg(t, t') \rho \mid \rho \in sort-down-subs(t, t') \} \).

**Example 4.** Continuing Example 3, we have that \( ssg(t, t') = \{ f(z:C), f(z:D) \} \), with \( sort-down-subs(t, t') = \{ \{ x:E \mapsto z:C \}, \{ x:E \mapsto z:D \} \} \).
Theorem 6. Given terms $t$ and $t'$ such that $[LS(t)] = [LS(t')]$, it holds that 1) $tsg(t, t')$ is a generalization of $t$ and $t'$, and 2) $ssg(t, t')$ provides a minimal and complete set of order-sorted lggs.

Proof. It is immediate that $tsg(t, t')$ is a generalization of $t$ and $t'$, since for each conflict pair $(s, s')$, the term $tsg(t, t')$ contains a variable at the corresponding conflict position of $t$ and $t'$ which has the top sort associated to $s$ and $s'$.

We prove that $ssg(t, t')$ provides a minimal complete set of order-sorted lggs by contradiction. First, let us prove that it is complete by assuming that there is a generalization $u$ of $t$ and $t'$ s.t. there is no $u' \in ssg(t, t')$ with $u \leq u'$. By definition of $tsg(t, t')$, we either have that $u \leq tsg(t, t')$ or $tsg(t, t') \leq u$. If $u \leq tsg(t, t')$, there must be a term $u' \in ssg(t, t')$ such that $u \leq u'$. If $tsg(t, t') \leq u$, then at least one of the variables $x_i:s_i$ of a conflict pair must have been instantiated with a variable $z:s$ such that $s \leq s_i$, but then there must be a term $u' \in ssg(t, t')$ such that $u \leq u'$. Thus, the conclusion follows.

Second, let us prove that it is minimal by assuming that there are two generalizations $u, u'$ of $t$ and $t'$ s.t. $u \in ssg(t, t')$, $u' \in ssg(t, t')$, and $u < u'$. If $u < u'$, then at least one of the variables $x_i:s_i$ of $u$ corresponding to a conflict pair $(u_i, v_i)$ must have been instantiated with a variable $x'_i:s'_i$ of $u'$ such that $s'_i < s_i$, which is impossible by definition of $LUBS(LS(u_i), LS(v_i))$. □

4.3. Correctness and Completeness of the order-sorted lgg calculus

Before proving correctness and completeness of the order-sorted lgg calculus given in Figure 3, we provide some auxiliary notions and lemmata.

The first lemma links the constraints with positions in terms $t$ and $t'$ of a generalization problem.

Lemma 8. Given terms $t$ and $t'$ such that $[s] = [LS(t)] = [LS(t')]$, and a fresh variable $x:[s]$, $(t \triangleq t' | \emptyset | id) \rightarrow^* (u \triangleq v \land CT | S | \emptyset)$ using the inference rules of Figure 3 if there exists a position $p$ of $t$ and $t'$ such that $t|_p = u$ and $t'|_p = v$, and $[s] = [LS(u)] = [LS(v)]$.

Proof. Straightforward by successive application of the Decompose inference rule of Figure 3. □

The following lemma links constraints already solved (and thus saved in the store) with conflict positions of terms $t$ and $t'$ of a generalization problem.

Lemma 9. Given terms $t$ and $t'$ such that $[s] = [LS(t)] = [LS(t')]$, and a fresh variable $x:[s]$ such that $(t \triangleq t' | \emptyset | id) \rightarrow^* (\emptyset | S | \emptyset)$ using the inference rules of Figure 3, the constraint $u \triangleq v$ belongs to $S$ if there exists a conflict pair $(u, v)$ of $t$ and $t'$ such that $s' \in LUBS(LS(u), LS(v))$. □
Proof. \((\Rightarrow)\) If \(u \not\leq v \in S\), then there must be a sort \(s''\) and two configurations
\[\langle u \not\leq v \wedge CT_1 \mid S_1 \mid \theta_1 \rangle, \langle CT_2 \mid u \not\leq v \wedge S_2 \mid \theta_2 \rangle\]
such that
\[x: [s] \Rightarrow (t \not\leq t' \mid \emptyset \mid id) \Rightarrow^* \langle u \not\leq v \wedge CT_1 \mid S_1 \mid \theta_1 \rangle \Rightarrow (CT_2 \mid u \not\leq v \wedge S_2 \mid \theta_2) \Rightarrow^* \langle \emptyset \mid S \mid \theta \rangle,\]

\[u \not\leq v \not\in S_1, u \not\leq v \not\in CT_2, s' \leq s'', \text{ and } \text{root}(u) \neq \text{root}(v).\]
By Lemma 8, there exists a position \(p\) of \(t\) and \(t'\) such that \(t|_p = u, t'|_p = v\), and \(s'' = [LS(u)] = [LS(v)]\). Since \(\text{root}(u) \neq \text{root}(v)\), \(p\) is a conflict position. Then, by application of the inference rule Solve, we have that \(s' \in LUBS(LS(u), LS(v))\).

\((\Leftarrow)\) By Lemma 8, there exists a sort \([s'']\) and a configuration \(\langle u \not\leq v \wedge CT_1 | S_1 | \theta_1 \rangle\) such that \(t \not\leq t' \mid \emptyset \mid id \Rightarrow^* \langle u \not\leq v \wedge CT_1 | S_1 | \theta_1 \rangle\), \(u \not\leq v \not\in S_1\), and \(\text{root}(u) \neq \text{root}(v)\). Then, the inference rule Solve is applied, i.e., \([u \not\leq v \wedge CT_1 | S_1 | \theta_1 \rangle \Rightarrow (CT_1 | u \not\leq v \wedge S_1 | \theta_1)\), and \(s' \in LUBS(LS(u), LS(v))\). Thus, the constraint \(u \not\leq v\) will be part of \(S\) in the final configuration \(\langle \emptyset \mid S \mid \theta \rangle\).

Lemma 10. Given terms \(t\) and \(t'\) such that \([s] = [LS(t)] = [LS(t')]\), for all \(S\) and \(\theta\) such that \(t \not\leq t' \mid \emptyset \mid id \Rightarrow^* \langle \emptyset \mid S \mid \theta \rangle\) using the inference rules of Figure 3, there exists a downgrading substitution \(\delta\) such that \(\text{tsg}(t, t')\delta = (x: [s])\theta\).

Proof. By successive application of the Decompose inference rule of Figure 3.

Theorem 7 (Correctness and Completeness). Given terms \(t\) and \(t'\) such that \([s] = [LS(t)] = [LS(t')]\), and a fresh variable \(x: [s]\), it holds that \(u\) is an order-sorted lgg of \(t\) and \(t'\) iff there exists \(S\) and \(\theta\) such that \(t \not\leq t' \mid \emptyset \mid id \Rightarrow^* \langle \emptyset \mid S \mid \theta \rangle\) using the inference rules of Figure 3 and \(u \simeq (x: [s])\theta\).

Proof. We reason by contradiction.

\((\Rightarrow)\) Let us consider a store \(S\) and substitution \(\theta\) such that there is no term \(u\) and renaming \(\rho\) with \(u\rho = (x: [s])\theta\). By Theorem 6, \(\text{tsg}(t, t') \leq u\) with a downgrading substitution \(\delta_u\), i.e., \(\text{tsg}(t, t')\delta_u = u\). By Lemma 10, \(\text{tsg}(t, t') \leq (x: [s])\theta\) with a downgrading substitution \(\delta\), i.e., \(\text{tsg}(t, t')\delta = (x: [s])\theta\). Since \((x: [s])\theta\) and \(u\) are not renamed variants and both terms are sort-specializations of \(\text{tsg}(t, t')\), there must be one binding \(x: [s] \Rightarrow x': [s']\) in \(\delta\) and one binding \(x: [s] \Rightarrow x'': [s'']\) in \(\delta_u\) s.t. either \(s' < s''\), \(s'' < s'\), or \([s'] \neq [s'']\). But all three possibilities are impossible by construction, since \(s' < s''\) contradicts the fact that \(u\) is a lgg, \(s'' < s'\) contradicts Lemma 9, and \([s'] \neq [s'']\) contradicts both that \(u\) is a lgg of \(t\) and \(t'\) and Lemma 9.

\((\Leftarrow)\) This case can be proven similarly.
5. Least General Generalizations modulo E

When we have an equational theory $E$, the notion of least general generalization has to be broadened, because, there may exist $E$-generalizable terms that do not have any (syntactic) least general generalization. Similarly to the dual case of $E$-unification, we have to talk about a set of least general $E$-generalizations (Baader [1991]).

For a set $M$ of terms, we define the set of most specific generalizations of $M$ modulo $E$ as the set of maximal lower bounds of $M$ under $\prec_E$, i.e.,

$$\text{lgg}_E(M) = \{u \mid \forall m \in M, u \leq_E m \land \not\exists u' (u <_E u' \land \forall m \in M, u' \leq_E m)\}.$$  

Example 5. Consider terms $t = f(a,a,b)$ and $s = f(b,b,a)$ where $f$ is associative and commutative, and $a$ and $b$ are constants. Terms $u = f(x,x,y)$ and $u' = f(x,a,b)$ are generalizations of $t$ and $s$ but they are not comparable, i.e., no one is an instance of the other modulo the AC axioms of $f$.

5.1. Recursively enumerating the least general generalizations modulo $E$

Given a finite set of equations $E$, and two terms $t$ and $s$, we can always recursively enumerate the set that is by construction a complete set of generalizations of $t$ and $s$. For this, we only need to recursively enumerate all pairs of terms $(u, u')$ with $t =_E u$ and $s =_E u'$ and compute $\text{lgg}(u, u')$. Of course, this set $\text{gen}_E(t, s)$ may easily be infinite. However, if the theory $E$ has the additional property that each $E$-equivalence class is finite and can be effectively generated, then the above process becomes a terminating algorithm, generating a finite complete set of generalizations of $t$ and $s$.

In any case, for any finite set of equations $E$, we can always mathematically characterize a minimal complete set of $E$-generalizations, namely the set $\text{lgg}_E(t, s)$ defined as follows. Roughly speaking, the minimal and complete set $\text{lgg}_E(t, s)$ is just the minimal set than can be obtained from a complete (generally non-minimal) set $\text{gen}_E(t, s)$ by filtering only the maximal elements of the set with regard to the ordering $\prec_E$, as also noted in [Pottier 1989].

Definition 8. Let $t$ and $s$ be terms and let $E$ be an equational theory. A complete set of generalizations of $t$ and $s$ modulo $E$, denoted by $\text{gen}_E(t, t')$, is defined as follows:

$$\text{gen}_E(t, t') = \{v \mid \exists u, u', t =_E u, t' =_E u', v \in \text{lgg}(u, u')\}.$$  

The set of least general generalizations of $t$ and $s$ modulo $E$ is defined as follows:

$$\text{lgg}_E(t, s) = \text{maximal}_{\prec_E}(\text{gen}_E(t, s))$$

where $\text{maximal}_{\prec_E}(S) = \{s \in S \mid \not\exists s' \in S : s <_E s'\}$. Lggs are equivalent modulo renaming and, therefore, we remove from $\text{lgg}_E(t, t')$ renamed versions (modulo $E$) of terms.
Our modular $E$-generalization algorithm defined below computes a complete set of generalizations, i.e., the set $\text{gen}_E(t, t')$, that must be filtered out to obtain the least general generalizations, i.e., the set $\text{lgg}_E(t, t')$. Let us prove that the set $\text{gen}_E(t, t')$ is a complete set of $E$-lggs.

Lemma 11. Given terms $t$ and $t'$ in an equational theory $E$, if $u$ is an lgg modulo $E$ of $t$ and $t'$, then there exists $u' \in \text{gen}_E(t, t')$ such that $u' \simeq_E u$.

Proof. By contradiction. Let $u$ be a lgg of $t$ and $s$ modulo $E$ and assume that there is no $u' \in \text{gen}_E(t, t')$ such that $u' \simeq_E u$. Since $u \leq_E t$ and $u \leq_E s$, there exist substitutions $\sigma_t$ and $\sigma_s$ such that $u \sigma_t =_E t$ and $u \sigma_s =_E s$. But then, $u \in \text{lgg}(u \sigma_t, u \sigma_s)$ (i.e., without making use of the equations $E$) and, by definition, $u \in \text{gen}_E(t, s)$, which contradicts the assumption.

Now, the minimality and completeness result for $\text{lgg}_E(t, t')$ follows straightforwardly.

Theorem 8. Given terms $t$ and $t'$ in an equational theory $E$, $\text{lgg}_E(t, t')$ is a minimal, correct, and complete set of lggs modulo $E$ of $t$ and $t'$ (up to renaming).

Proof. Lemma 11 ensures that $\text{gen}_E(t, t')$ is a complete set of lggs. Minimality of the set $\text{lgg}_E(t, t')$ is ensured by maximality of the relation $<_E$. 

However, note that in general the relation $t <_E t'$ is undecidable, so that the above set, although definable at the mathematical level, might not be effectively computed. Nevertheless, when: (i) each $E$-equivalence class is finite and can be effectively generated, and (ii) there is an $E$-matching algorithm, then we also have an effective algorithm for computing $\text{lgg}_E(t, s)$, since the relation $t \leq_E t'$ is precisely the $E$-matching relation.

In summary, when $E$ is finite and satisfies conditions (i) and (ii), the above definitions give us a feasible, although horribly inefficient, procedure to compute a finite, minimal, and complete set of least general generalizations $\text{lgg}_E(t, s)$, because the cardinality of the $E$-equivalence classes can be exponential in the size of their elements, as in the case of associative-commutative theories [Pottier 1989]: for instance, if $f$ is AC, then the class $E$ for $f(a_1, f(a_2, ..., f(a_{n-1}, a_n)...) has $(2n - 2)!/(n - 1)!$ elements. This naive algorithm could be used when $E$ consists of associativity and/or commutativity axioms for some functions symbols, because such theories (a special case of our proposed parametric family of theories) all satisfy conditions (i)–(ii). However, when we add identity axioms, $E$-equivalence classes become infinite, so that the above approach no longer gives us a lgg algorithm modulo $E$.

In the following sections, we do provide a modular, minimal, terminating, sound, and complete algorithm for equational theories containing different axioms such as associativity, commutativity, and identity (and their combinations). This algorithm computes the set $\text{gen}_E(t, t')$ modulo $E$ and renaming. The set $\text{lgg}_E(t, s)$ of least general $E$-generalizations can be computed as in Definition 8. That is: first a complete set of $E$-generalizations is computed by the inference
rules given below, and then they are filtered to obtain \( \text{lgg}_E(t, s) \) by using the fact that, for all theories \( E \) in the parametric family of theories we consider in this paper, there is a matching algorithm modulo \( E \) that provides the relation \( <_E \). We consider that a given function symbol \( f \) in the signature \( \Sigma \) obeys a subset of axioms \( \text{ax}(f) \subseteq \{ A_f, C_f, U_f \} \). In particular, \( f \) may not satisfy any such axioms, i.e., \( \text{ax}(f) = \emptyset \). Note that, technically, variables of the original terms are handled in our rules as constants, thus without any attribute, i.e., for any variable \( x \in X \), we consider \( \text{ax}(x) = \emptyset \).

Let us provide our inference rules for equational generalization in a stepwise manner. First, \( \text{ax}(f) = \emptyset \) in Section 5.2, then, \( \text{ax}(f) = \{ C_f \} \) in Section 5.3, then, \( \text{ax}(f) = \{ A_f, C_f \} \) in Section 5.4, and finally, \( U_f \in \text{ax}(f) \) in Section 5.6. In each section, proofs of correctness and completeness are very similar to the ones in Section 3.2 and, thus, we define a key notion of conflict pair for each equational property (i.e., commutative conflict pairs, associative conflict pairs, associative-commutative conflict pairs, and identity conflict pairs) which is the basis for our overall proof scheme. For readability, we have provided complete proofs, even if they are in several aspects similar and differ mainly in the different conflict pair notions, which make it impossible to structure the proof in a parametric way.

### 5.2. Basic inference rules for least general \( E \)-generalization

Let us start with a set of basic rules that are the equational version of the syntactic generalization rules of Section 3. The rule \( \text{Decompose}_E \) applies to function symbols obeying no axioms, \( \text{ax}(f) = \emptyset \). Specific rules for decomposing constraints involving terms that are rooted by symbols obeying equational axioms, such as ACU and their combinations, are given below.

Concerning the rules \( \text{Solve}_E \) and \( \text{Recover}_E \), the main difference w.r.t. the corresponding syntactic generalization rules given in Section 3 is in the fact that the checks to the store consider the constraints modulo \( E \): in the rules below, we write \( (t \overset{y}{=} t') \in^E S \) to express that there exists \( u \overset{y}{=} u' \in S \) such that \( t =_E u \) and \( t' =_E u' \).

Finally, regarding the rule \( \text{Solve}_E \), note that this rule cannot be applied to any constraint \( t \overset{x}{=} s \) such that either \( t \) or \( s \) are rooted by a function symbol \( f \) with \( U_f \in \text{ax}(f) \). For function symbols with an identity element, a specially-tailored rule \( \text{Expand}_U \) is given in Section 5.6 that gives us the opportunity to solve a constraint (conflict pair) \( f(t_1, t_2) \overset{x}{=} s \), such that \( \text{root}(s) \neq f \), with a generalization \( f(y, z) \) more specific than \( x \), by first introducing the constraint \( f(t_1, t_2) \overset{x}{=} f(s, e) \).

Termination, correctness and completeness of the basic algorithm are straightforward by reasoning similarly to the syntactic case of Section 3.

**Theorem 9 (Termination).** Given an equational theory \((\Sigma, E)\), \( \Sigma \)-terms \( t \) and \( t' \) such that every symbol in \( t \) and \( t' \) is free, and a fresh variable \( x \), every derivation stemming from an initial configuration \( (t \overset{x}{=} t' \mid \emptyset \mid \text{id}) \) using the inference rules of Figure 6 terminates with a configuration \( (\emptyset \mid S \mid \theta) \).
\[ f \in (\Sigma \cup X) \land ax(f) = \emptyset \]
\[ \langle f(t_1, \ldots, t_n) \rangle_{x\sigma} = \langle f(t_1', \ldots, t_n') \rangle_{x\sigma} \]
\[ \langle \theta \rangle \quad \text{where} \quad \theta = \{ x \mapsto f(b, a), x_3 \mapsto b, x_4 \mapsto a \}, \text{thus we conclude that the lgg modulo } C \text{ of } t \text{ and } s \text{ is } x\theta = f(b, a). \]

**Theorem 10 (Correctness and Completeness).** Given an equational theory \( (\Sigma, E) \), \( \Sigma \)-terms \( t \) and \( t' \) such that every symbol in \( t \) and \( t' \) is free, and a fresh variable \( x \), then \( u \in gen_E(t, t') \) iff there is \( u' \) in \( \{ x\theta | (t \triangleq t' \mid \emptyset | \text{id} \rightarrow^* (\emptyset | S | \theta) \} \) using the inference rules of Figure 6 such that \( u \approx u' \).

**Proof.** It follows directly from Theorem 1.

5.3. **Least general generalization modulo** \( C \)

In this section we extend the basic set of equational generalization rules by adding a specific inference rule \( \text{Decompose}_{CE} \), given in Figure 7, for dealing with commutativity function symbols. This inference rule replaces the syntactic decomposition inference rule for the case of a binary commutative symbol \( f \), i.e., the two possible rearrangements of the terms \( f(t_1, t_2) \) and \( f(t_1', t_2') \) are considered. Just notice that this rule is (don’t know) non-deterministic, hence all four combinations must be explored.

**Example 6.** Let \( t = f(a, b) \) and \( s = f(b, a) \) be two terms where \( f \) is commutative, i.e., \( ax(f) = \{ C_f \} \). By applying the rules \( \text{Solve}_E \), \( \text{Recover}_E \), and \( \text{Decompose}_{CE} \) above, we end in a terminal configuration \( (\emptyset | S | \theta) \), where \( \theta = \{ x \mapsto f(b, a), x_3 \mapsto b, x_4 \mapsto a \} \), thus we conclude that the lgg modulo \( C \) of \( t \) and \( s \) is \( x\theta = f(b, a) \).

Termination is straightforward.
Theorem 11 (Termination). Given an equational theory \((\Sigma, E)\), \(\Sigma\)-terms \(t\) and \(t'\) such that every symbol in \(t\) and \(t'\) is free or commutative, and a fresh variable \(x\), every derivation stemming from an initial configuration \(\langle t \overset{\sigma}{=} t' \mid \emptyset \mid \text{id} \rangle\) using the inference rules of Figures 6 and 7 terminates with a configuration \(\langle \emptyset \mid S \mid \theta \rangle\).

Proof. Similar to the proof of Theorem 1 by considering the two possible rearrangements of each term. \(\square\)

In order to prove correctness and completeness of the lgg calculus modulo \(C\), similarly to Definition 2 we introduce the auxiliary concept of commutative conflict pair, and prove some useful results for this case.

First, we prove an auxiliary result stating that only (independently) fresh variables \(y\) appear in the index positions of the constraints in \(CT\) and \(S\) components of lgg configurations.

Lemma 12 (Uniqueness of Generalization Variables). Lemma 7 holds for \(t \overset{\sigma}{=} t'\) when the symbols in \(t\) and \(t'\) are free or commutative, for the inference rules of Figures 6 and 7.

The first lemma states that the range of the substitutions partially computed at any stage of a generalization derivation coincides with the set of the index variables of the configuration.

Lemma 13. Given terms \(t\) and \(t'\) such that every symbol in \(t\) and \(t'\) is free or commutative, and a fresh variable \(x\) such that \(\langle t \overset{\sigma}{=} t' \mid \emptyset \mid \text{id} \rangle \rightarrow^{*} \langle CT \mid S \mid \theta \rangle\), then \(\text{Index}(S \cup CT) \subseteq \text{Ran}(\theta)\), and \(\text{Ran}(\theta) = \text{Var}(x\theta)\).

Proof. Immediate by construction. \(\square\)

The following lemma establishes an auxiliary property that is useful for defining the notion of a commutative conflict pair of terms. The depth of a position is defined as \(\text{depth}(\Lambda) = 0\) and \(\text{depth}(i.p) = 1 + \text{depth}(p)\); in other words, it is the length of the sequence \(p\). Given a position \(p\) with depth \(n\), \(p|_k\) is the (prefix) position \(p\) at depth \(k \leq n\), i.e., \(p|_0 = \Lambda\), \((i.p)|_k = i.(p|_{k-1})\) if \(k > 0\). For instance, for \(p = 1.2.1.3\), \(p|_3 = 1.2.1\).
Lemma 14. Given terms $t$ and $t'$ such that every symbol in $t$ and $t'$ is free or commutative, and a fresh variable $x$, $(\langle t \bowtie t' \mid \emptyset \mid id \rangle \rightarrow^* \langle u \bowtie v \bowtie CT \mid S \mid \theta \rangle)$ using the inference rules of Figures 6 and 7 if and only if there exist a position $p \in Pos(t)$ and a position $p' \in Pos(t')$ such that $t|_p = u$, $t'|_{p'} = v$, $\text{depth}(p) = \text{depth}(p')$, and $\forall 1 \leq i \leq \text{depth}(p)$, $\text{root}(t|_p)_i = \text{root}(t'|_{p'})_i$.

PROOF. Straightforward by successive application of the inference rule Decompose of Figure 8 and the inference rule Decompose$^C_v$ of Figure 9. □

Definition 9 (Commutative Conflict Pair). Given terms $t$ and $t'$ such that every symbol in $t$ and $t'$ is free or commutative, the pair $(u, v)$ is called a commutative conflict pair of $t$ and $t'$ if and only if $u \neq v \bowtie v$ and there exist at least one position $p \in Pos(t)$ and at least one position $p' \in Pos(t')$ such that $t|_p = u$, $t'|_{p'} = v$, $\text{depth}(p) = \text{depth}(p')$, and $\forall 1 \leq i \leq \text{depth}(p)$, $\text{root}(t|_p)_i = \text{root}(t'|_{p'})_i$.

The following lemma states the appropriate connection between the constraints in a derivation and the commutative conflict pairs of the initial configuration.

Lemma 15. Given terms $t$ and $t'$ such that every symbol in $t$ and $t'$ is free or commutative, and a fresh variable $x$, $(\langle t \bowtie t' \mid \emptyset \mid id \rangle \rightarrow^* \langle CT \mid u \bowtie v \bowtie S \mid \theta \rangle)$ using the inference rules of Figures 6 and 7 if and only if $(u, v)$ is a commutative conflict pair of $t$ and $t'$.

PROOF. $(\Rightarrow)$ If $u \bowtie v \in S$, then there must be two configurations $\langle u \bowtie v \bowtie CT_1 \mid S_1 \mid \theta_1 \rangle$, $\langle CT_2 \mid u \bowtie v \bowtie S_2 \mid \theta_2 \rangle$ such that $\langle t \bowtie t' \mid \emptyset \mid id \rangle \rightarrow^* \langle u \bowtie v \bowtie CT_1 \mid S_1 \mid \theta_1 \rangle \rightarrow \langle CT_2 \mid u \bowtie v \bowtie S_2 \mid \theta_2 \rangle \rightarrow^* \langle \emptyset \mid S \mid \theta \rangle$, $u \bowtie v \notin S_1$, $u \bowtie v \notin CT_2$, and $\text{root}(u) \neq \text{root}(v)$. By Lemma 14, there exists a position $p \in Pos(t)$ and a position $p' \in Pos(t')$ such that $t|_p = u$, $t'|_{p'} = v$, $\text{depth}(p) = \text{depth}(p')$, and $\forall 1 \leq i \leq \text{depth}(p)$, $\text{root}(t|_p)_i = \text{root}(t'|_{p'})_i$. Therefore, $(u, v)$ is a commutative conflict pair.

$(\Leftarrow)$ By Lemma 14, there is a configuration $\langle u \bowtie v \bowtie CT_1 \mid S_1 \mid \theta_1 \rangle$ such that $\langle t \bowtie t' \mid \emptyset \mid id \rangle \rightarrow^* \langle u \bowtie v \bowtie CT_1 \mid S_1 \mid \theta_1 \rangle$, $u \bowtie v \notin S_1$, and $\text{root}(u) \neq \text{root}(v)$. Then, the inference rule Solve is applied, i.e., $\langle u \bowtie v \bowtie CT_1 \mid S_1 \mid \theta_1 \rangle \rightarrow \langle CT_1 \mid u \bowtie v \bowtie S_1 \mid \theta_1 \rangle$ and $u \bowtie v$ will be part of $S$ in the final configuration $\langle \emptyset \mid S \mid \theta \rangle$. □

The following lemma establishes the link between the computed substitution and a proper generalization term.

Lemma 16. Given terms $t$ and $t'$ such that every symbol in $t$ and $t'$ is free or commutative, and a fresh variable $x$, $(\langle t \bowtie t' \mid \emptyset \mid id \rangle \rightarrow^* \langle C \mid S \mid \theta \rangle)$, using the inference rules of Figures 6 and 7 if $x\theta$ is a generalization of $t$ and $t'$ modulo commutativity.
Proof. By structural induction on the term \( x\theta \). If \( x\theta = x \), then \( \theta = id \) and the conclusion follows. If \( x\theta = f(u_1, \ldots, u_k) \) and \( f \) is free, then the inference rule Decompose\(_F\) of Figure 6 is applied and we have that \( t = f(t_1, \ldots, t_k) \) and \( t' = f(t'_1, \ldots, t'_k) \). If \( x\theta = f(u_1, \ldots, u_k) \) and \( f \) is commutative, then the inference rule Decompose\(_C\) of Figure 7 is applied and we have that either: (i) \( t = f(t_1, t_2) \) and \( t' = f(t'_1, t'_2) \), or (ii) \( t = f(t_1, t_2) \) and \( t' = f(t'_2, t'_1) \), or (iii) \( t = f(t_2, t_1) \) and \( t' = f(t'_1, t'_2) \), or (iv) \( t = f(t_2, t_1) \) and \( t' = f(t'_2, t'_1) \). By induction hypothesis, \( u_i \) is a generalization of \( t_i \) and \( t'_i \), for each \( i \). Now, if for each pair of terms in \( u_1, \ldots, u_k \) there are no shared variables, then the conclusion follows. Otherwise, for each variable \( z \) shared between two different terms \( u_i \) and \( u_j \), there is a constraint \( w_1 \neq w_2 \in S \) and, by Lemma 15, there is a commutative conflict pair \( (w_1, w_2) \) in \( t_i \) and \( t'_i \). Thus, the conclusion follows. \( \square \)

Finally, correctness and completeness are proved as follows.

**Theorem 12 (Correctness and Completeness).** Given an equational theory \( (\Sigma, E) \), \( \Sigma \)-terms \( t \) and \( t' \) such that every symbol in \( t \) and \( t' \) is free or commutative, and a fresh variable, then \( u \in gen_E(t, t') \) iff there is \( u' \) in \( \{x\theta | (t \equiv t' \mid \emptyset \mid id) \rightarrow^* \langle S \mid \theta \rangle\} \) using the inference rules of Figures 4 and 5 such that \( u \approx_E u' \).

Proof. By contradiction. By Lemma 16, \( x\theta \) is a generalization of \( t \) and \( t' \). If \( x\theta \) is not a generalization of \( t \) and \( t' \) up to renaming, then there is a term \( u \) which is a generalization of \( t \) and \( t' \) and a substitution \( \rho \) which is not a variable renaming such that \( x\theta \rho = E u \). By Lemma 13, \( Ran(\theta) = Var(x\theta) \), hence we can choose \( \rho \) with \( Dom(\rho) = Var(x\theta) \). Since \( \rho \) is not a variable renaming, either:

1. there are variables \( y, y' \in Var(x\theta) \) and a variable \( z \) such that \( y\rho = y'\rho = z \), or
2. there is a variable \( y \in Var(x\theta) \) and a non-variable term \( v \) such that \( y\rho = v \).

In case 1, there are two positions \( p, p' \) in \( u \) such that \( u|_p = z = u|_{p'} \). Moreover, there is a position \( q \) in \( x\theta \) such that \( (x\theta)|_q = y \) and the pair \( (y, z) \) is a conflict pair of \( x\theta \) and \( u \). Similarly there is a position \( q' \) in \( x\theta \) such that \( (x\theta)|_{q'} = y' \) and the pair \( (y', z) \) is a conflict pair of \( x\theta \) and \( u \). But this also means that there is a position \( q_t \) in \( t \) such that \( t|_{q_t} = w_1 \) and the pair \( (w_1, z) \) is a conflict pair of \( t \) and \( u \); and there is a position \( q'_t \) in \( t' \) such that \( t'|_{q'_t} = w_2 \) and the pair \( (w_2, z) \) is a conflict pair of \( t' \) and \( u \). But this is impossible by Lemmas 15 and 13. In case 2, there is a position \( p \) such that \( (x\theta)|_p = y \) and, since \( y\rho = v \) and \( v \) is a non-variable term, then \( p \) is not involved in any conflict pair of \( t \) and \( t' \). But this is again impossible by Lemmas 15 and 13. \( \square \)

We recall again that in general the inference rules of Figures 4 and 7 together are not confluent, and different final configurations \( \langle \emptyset \mid S_1 \mid \theta_1 \rangle, \ldots, \langle \emptyset \mid S_n \mid \theta_n \rangle \) correspond to different generalizations \( x\theta_1, \ldots, x\theta_n \).
Decompose$_A$

\[
A_f \in \text{ax}(f) \land C_f \not\in \text{ax}(f) \land m \geq 2 \land n \geq m \land k \in \{1, \ldots, (n - m) + 1\}
\]

\[
\langle f(t_1, \ldots, t_n) \rangle \triangleq f(t'_1, \ldots, t'_m) \land CT \mid S \mid \theta \rightarrow
\]

\[
\langle f(t_1, \ldots, t_k) \rangle \triangleq t'_1 \land f(t_{k+1}, \ldots, t_n) \triangleq f(t'_2, \ldots, t'_m) \land CT \mid S \mid \theta \sigma \rangle
\]

where \( \sigma = \{ x \mapsto f(x_1, x_2) \} \), and \( x_1, x_2 \) are fresh variables

Figure 8: Decomposition rule for an associative (non–commutative) function symbol \( f \)

5.4. Least general generalization modulo \( A \)

In this section we provide a specific inference rule Decompose$_A$ for handling function symbols obeying the associativity axiom (but not the commutativity one). A specific set of rules for dealing with AC function symbols is given in the next subsection.

The Decompose$_A$ rule is given in Figure 8. We use flattened versions of the terms which use poly-variadic versions of the associative symbols, i.e., being \( f \) an associative symbol, with \( n \) arguments, and \( n \geq 2 \), flattened terms are canonical forms w.r.t. the set of rules given by the following rule schema

\[
f(x_1, \ldots, f(t_1, \ldots, t_n), \ldots, x_m) \rightarrow f(x_1, \ldots, t_1, \ldots, t_n, \ldots, x_m) \quad n, m \geq 2
\]

Given an associative symbol \( f \) and a term \( f(t_1, \ldots, t_n) \) we call \( f \)-alien terms (or simply alien terms) to those terms among \( t_1, \ldots, t_n \) that are not rooted by \( f \). In the following, being \( f \) an associative poly-variadic symbol, by convention \( f(t) \) represents the term \( t \) itself, since symbol \( f \) needs at least two arguments. The inference rule of Figure 8 replaces the syntactic decomposition inference rule for the case of an associative function symbol \( f \), where all prefixes of \( t_1, \ldots, t_n \) and \( t'_1, \ldots, t'_m \) are considered. Note that this rule is (don’t know) non-deterministic, hence all possibilities must be explored.

This inference rule for associativity is better than generating all terms in the corresponding equivalence class, as explained in Section 4, since we will eagerly stop the computation whenever we find a constraint \( t \not\equiv f(t_1, \ldots, t_n) \) such that root\((t) \neq f \) without considering all the combinations in the equivalence class of \( f(t_1, \ldots, t_n) \).

We give the rule Decompose$_A$ for the case when, in the generalization problem \( f(t_1, \ldots, t_n) \not\equiv f(s_1, \ldots, s_m) \), we have that \( n \geq m \). For the other way around, i.e., \( n < m \), a similar rule would be needed, that we omit since it is entirely similar. The following example illustrates the least general generalization modulo \( A \).

Example 7. Let \( t = f(f(a, c), b) \) and \( t' = f(c, b) \) be two terms where \( f \) is associative, i.e., \( \text{ax}(f) = \{ A_f \} \). By applying the rules Solve$_E$, Recover$_E$, and Decompose$_A$ above, we end in a terminal configuration \( \emptyset \mid S \mid \theta \), where \( \theta = \{ x \mapsto f(x_3, b), x_4 \mapsto b \} \), thus we obtain that the lgg modulo \( A \) of \( t \) and \( t' \) is \( f(x_3, b) \). The computation trace is shown in Figure 7.
$\text{lgg}_E(f(f(a, c), b), f(c, b))$, with $E = \{A_f\}$

Initial Configuration

$(f(a, c, b) \triangleleft f(c, b) | \emptyset | \emptyset)$

Decompose

$(a \triangleleft f(c, b) \triangledown b | \emptyset | \{x \mapsto f(x_1, x_2)\})$

$(f(a, c) \triangleleft c \wedge b \triangledown b | \emptyset | \{x \mapsto f(x_3, x_4)\})$

Solve

$(f(c, b) \triangledown b | a \triangledown c | \{x \mapsto f(x_1, x_2)\})$

$(b \triangledown b | f(a, c) \triangledown c | \{x \mapsto f(x_3, x_4)\})$

Decompose

$(\emptyset | a \triangledown c \wedge f(c, b) \triangledown b | \{x \mapsto f(x_1, x_2)\})$

$(\emptyset | f(a, c) \triangledown c | \{x \mapsto f(x_3, b), x_4 \mapsto b\})$

Figure 9: Computation trace for $A$–generalization of terms $f(f(a, c) b)$ and $(f(c, b))$.

Note that in the example above there is a unique lgg modulo $A$, although this is not true for some generalization problems as witnessed by the following example.

**Example 8.** Let $t = f(f(a, a), f(b, b))$ and $t' = f(f(b, b), b)$ be two terms where $f$ is associative, i.e., $\text{ax}(f) = \{A_f\}$. By applying the rules $\text{Solve}_E$, $\text{Recover}_E$, and $\text{Decompose}_A$ above, we end in two terminal configurations $\langle \emptyset | S_1 \| \theta_1 \rangle$ and $\langle \emptyset | S_2 \| \theta_2 \rangle$, where $\theta_1 = \{x \mapsto f(f(x, x), y)\}$ and $\theta_2 = \{x \mapsto f(f(y, b), b)\}$. Both are more general terms.

Termination is straightforward.

**Theorem 13 (Termination).** Given an equational theory $(\Sigma, E)$, $\Sigma$-terms $t$ and $t'$ such that every symbol in $t$ and $t'$ is free or associative, and $x$ a fresh variable, every derivation stemming from an initial configuration $\langle x \triangledown t' \| \emptyset \| \emptyset \rangle$ using the inference rules of Figures 6 and 8 terminates with a configuration $\langle \emptyset | S \| \emptyset \rangle$.

**Proof.** Similar to the proof of Theorem 1 by simply considering the flattened versions of the terms. □

In order to prove correctness and completeness of the lgg calculus modulo $A$, similarly to Definitions 2 and 9, we introduce the auxiliary concept of an associative conflict pair, and prove some related, auxiliary results.

First, we prove an auxiliary result stating that only (independently) fresh variables $y$ appear in the index positions of the constraints in $CT$ and $S$ components of lgg configurations.

**Lemma 17 (Uniqueness of Generalization Variables).** Lemma 1 holds for $t \triangleleft t'$ when the symbols in $t$, $t'$ are free or associative, for the inference rules of Figures 6 and 8.

The lemma below states that the range of the substitutions partially computed at any stage of a generalization derivation coincides with the set of the index variables of the configuration.
Lemma 18. Given terms $t$ and $t'$ such that every symbol in $t$ and $t'$ is free or associative, and a fresh variable $x$ such that $\langle t \hat{=} t' \mid \emptyset \mid \text{id} \rangle \rightarrow^* \langle CT_1 \mid S \mid \emptyset \rangle$ using the inference rules of Figures 6 and 8, if there exists a position $p$ or associative, and a fresh variable $x$ such that every symbol in flattened terms. Proof. Immediate by construction.

Lemma 19. Given flattened terms $t$ and $t'$ such that every symbol in $t$ and $t'$ is free or associative, and a fresh variable $x$, $\langle t \hat{=} t' \mid \emptyset \mid \text{id} \rangle \rightarrow^* \langle u \hat{=} v \wedge CT \mid S \mid \emptyset \rangle$ using the inference rules of Figures 6 and 8, if there exists a position $p$ or associative, and a fresh variable $x$ such that every symbol in flattened terms.

Proof. Straightforward by successive application of the inference rule Decompose of Figure 1 and the inference rule DecomposeA of Figure 8.

Definition 10 (Associative Conflict Pair). Given flattened terms $t$ and $t'$ such that every symbol in $t$ and $t'$ is free or associative, the pair $(u, v)$ is called an associative conflict pair of $t$ and $t'$ if there exist at least one position $p \in Pos(t')$ such that either:

1. $t|_p = u$, $t'|_{p'} = v$, $\text{depth}(p) = \text{depth}(p')$, and $\forall 1 \leq i \leq \text{depth}(p)$, $\text{root}(t|_{p|_i}) = \text{root}(t'|_{p'|_i});$

2. $t|_p = u$, $v = f(v_1, \ldots, v_n)$, $t'|_{p'} = f(w_1, \ldots, w_m, v_1, \ldots, v_n, w'_1, \ldots, w'_m)$, $f$ is associative, $\text{depth}(p) = \text{depth}(p') + 1$, and $\forall 1 \leq i \leq \text{depth}(p')$, $\text{root}(t|_{p|_i}) = \text{root}(t'|_{p'|_i});$

3. $u = f(u_1, \ldots, u_n)$, $t|_p = f(w_1, \ldots, w_m, u_1, \ldots, u_n, w'_1, \ldots, w'_m)$, $t'|_{p'} = v$, $f$ is associative, $\text{depth}(p') = \text{depth}(p) + 1$, and $\forall 1 \leq i \leq \text{depth}(p)$, $\text{root}(t|_{p|_i}) = \text{root}(t'|_{p'|_i});$

4. $u = f(u_1, \ldots, u_k)$, $t|_p = f(x_1, \ldots, x_m, u_1, \ldots, u_k)$, $v = f(v_1, \ldots, v_n)$, $t'|_{p'} = f(w_1, \ldots, w_m, v_1, \ldots, v_n)$, $f$ is associative, $\text{depth}(p) = \text{depth}(p')$, and $\forall 1 \leq i \leq \text{depth}(p)$, $\text{root}(t|_{p|_i}) = \text{root}(t'|_{p'|_i}).$
Note that the least general generalization of terms \( f(a, c, d, b) \) and \( f(a, e, e, b) \) is \( f(a, x_1, x_2, b) \) instead of \( f(a, x_1, b) \), which may seem the most natural choice. Only when the number of elements is different, a variable takes care of one element of the shortest list and the remaining elements of the longer list, e.g., the least general generalization of terms \( f(a, c, d, b) \) and \( f(a, e, e, e, c, b) \) is again \( f(a, x_1, x_2, b) \), where \( x_2 \) takes care of \( d \) and \( f(e, e, e) \).

The following lemma states the appropriate connection between the constraints in a derivation and the associative conflict pairs of the initial configuration.

**Lemma 20.** Given flattened terms \( t \) and \( t' \) such that every symbol in \( t \) and \( t' \) is free or associative, and a fresh variable \( x \), \( \langle \xi \triangleq t' \mid \emptyset \mid id \rangle \rightarrow^* \langle CT \mid u \triangleq v \land S \mid \theta \rangle \) using the inference rules of Figures 6 and 8 iff \( (u, v) \) is an associative conflict pair of \( t \) and \( t' \).

**Proof.** (\( \Rightarrow \)) If \( u \triangleq v \in S \), then there must be two configurations \( \langle u \triangleq v \land CT_1 \mid S_1 \mid \theta_1 \rangle, \langle CT_2 \mid u \triangleq v \land S_2 \mid \theta_2 \rangle \) such that

\[
\langle \xi \triangleq t' \mid \emptyset \mid id \rangle \rightarrow^* \langle u \triangleq v \land CT_1 \mid S_1 \mid \theta_1 \rangle \rightarrow \langle CT_2 \mid u \triangleq v \land S_2 \mid \theta_2 \rangle \rightarrow^* \langle \emptyset \mid S \mid \theta \rangle,
\]

\( u \triangleq v \notin S_1, u \triangleq v \notin CT_2 \), and \( \root(u) \neq \root(v) \). By Lemma 19, there exist a position \( p \in \pos(t) \) and a position \( p' \in \pos(t') \) such that either:

1. \( t\mid_p = u, t\mid_{p'} = v, \depth(p) = \depth(p'), \) and \( \forall 1 \leq i \leq \depth(p), \root(t\mid_{p\downarrow i}) = \root(t\mid_{p'\downarrow i}) \); or
2. \( t\mid_p = u, v = f(v_1, \ldots, v_n), t\mid_{p'} = f(w_1, \ldots, w_m, v_1, \ldots, v_n, w'_1, \ldots, w'_m), \)
   \( f \) is associative, \( \depth(p) = \depth(p') + 1 \), and \( \forall 1 \leq i \leq \depth(p'), \)
   \( \root(t\mid_{p\downarrow i}) = \root(t\mid_{p'\downarrow i}) \); or
3. \( u = f(u_1, \ldots, u_n), t\mid_p = f(w_1, \ldots, w_m, u_1, \ldots, u_n, w'_1, \ldots, w'_m), t\mid_{p'} = v, \)
   \( f \) is associative, \( \depth(p') = \depth(p) + 1 \), and \( \forall 1 \leq i \leq \depth(p), \)
   \( \root(t\mid_{p\downarrow i}) = \root(t\mid_{p'\downarrow i}) \).

Note that, since \( \root(u) \neq \root(v) \), the fourth case of Lemma 19 is not possible. Therefore, either \( (u, v) \) (or \( (u, f(v_1, \ldots, v_n)) \)) is an associative conflict pair.

(\( \Leftarrow \)) By Lemma 19, there is a configuration \( \langle u \triangleq v \land CT_1 \mid S_1 \mid \theta_1 \rangle \) such that

\[
\langle \xi \triangleq t' \mid \emptyset \mid id \rangle \rightarrow^* \langle u \triangleq v \land CT_1 \mid S_1 \mid \theta_1 \rangle, u \triangleq v \notin S_1, \) and \( \root(u) \neq \root(v) \).

Then, the inference rule Solve is applied, i.e., \( \langle u \triangleq v \land CT_1 \mid S_1 \mid \theta_1 \rangle \rightarrow \langle CT_1 \mid u \triangleq v \land S_1 \mid \theta_1 \rangle \) and \( u \triangleq v \) will be part of \( S \) in the final configuration \( \langle \emptyset \mid S \mid \theta \rangle \).

Finally, the following lemma establishes the link between the computed substitution and a proper generalization term.

**Lemma 21.** Given flattened terms \( t \) and \( t' \) such that every symbol in \( t \) and \( t' \) is free or associative, and a fresh variable \( x \), \( \langle \xi \triangleq t' \mid \emptyset \mid id \rangle \rightarrow^* \langle C \mid S \mid \theta \rangle \)
using the inference rules of Figures 6 and 8 iff $x\theta$ is a generalization of $t$ and $t'$ modulo associativity.

**Proof.** By structural induction on the term $x\theta$ (or $u$). If $x\theta = x$, then $\theta = id$ and the conclusion follows. If $x\theta = f(u_1, \ldots, u_k)$ and $f$ is free, then the inference rule Decompose$_E$ of Figure 6 is applied and we have that $t = f(t_1, \ldots, t_k)$ and $t' = f(t'_1, \ldots, t'_k)$. If $x\theta = f(u_1, \ldots, u_k)$ and $f$ is associative, then the inference rule Decompose$_A$ of Figure 8 is applied and we have that $t = f(u_1, \ldots, u_n)$, $t' = f(v_1, \ldots, v_m)$, and $k = \min(n, m)$. Let us consider the different values for $k$, $n$ and $m$.

- If $k = n = m$, then by induction hypothesis $t_i$ is a generalization of $u_i$ and $v_i$, for each $i \in \{1, \ldots, k\}$. Now, if there are no shared variables among all $t_i$, then the conclusion follows. Otherwise, for each variable $z$ shared between two different terms $t_i$ and $t_j$, there is a constraint $w_1 \not\equiv w_2 \in S$ and, by Lemma 20, there is a conflict pair $(w_1, w_2)$ in $t_i$ and $t'_j$. Thus, the conclusion follows.

- If $k = n$ and $\ell = m - n$, then there is an element $j \in \{1, \ldots, k\}$ such that by induction hypothesis $t_i$ is a generalization of $u_i$ and $v_i$ for each $i < j$, $t_j$ is a generalization of $u_j$ and $f(v_{j_1}, \ldots, v_{j_\ell})$, and $t_i$ is a generalization of $u_i$ and $v_{i+j}$ for each $i > j$. Now, if there are no shared variables among all $t_i$ s.t. $i \not= j$, then the conclusion follows. Otherwise, for each variable $z$ shared between two different terms $t_i$ and $t_j$ s.t. $i_1 \not= j$ and $i_2 \not= j$, there is a constraint $w_1 \not\equiv w_2 \in S$ and, by Lemma 20, there is a conflict pair $(w_1, w_2)$ in $t_i$ and $t'_j$. Thus, the conclusion follows. \hfill \Box

Finally, correctness and completeness are proved as follows.

**Theorem 14 (Correctness and Completeness).** Given an equational theory $(\Sigma, E)$, and flattened $\Sigma$-terms $t$ and $t'$ such that every symbol in $t$ and $t'$ is free or associative, and a fresh variable $x$, then $u \in gen_E(t, t')$ iff there is $u'$ in $
abla x \theta | \{ t \not\equiv t' \} \rightarrow^* \langle \emptyset | S | \theta \rangle$ using the inference rules of Figures 6 and 8 such that $u \simeq_E u'$.

**Proof.** Similar to Theorem 12. \hfill \Box

Recall that the inference rules of Figures 6 and Figure 8 together are not confluent, so that different final configurations $\langle \emptyset | S_1 | \theta_1 \rangle, \ldots, \langle \emptyset | S_n | \theta_n \rangle$ correspond to different generalizations $x\theta_1, \ldots, x\theta_n$.

5.5. Least general generalization modulo AC

In this section we provide a specific inference rule Decompose$_{AC}$ for handling function symbols obeying both the associativity and commutativity axioms. Note that we use again flattened versions of the terms, as in the associative case of Section 5.4. Actually, by considering AC function symbols as varyadic
Decompose$_{AC}$

\[
\begin{align*}
\{A_f, C_f\} \subseteq &\ ax(f) \land n \geq m \land \{i_1, \ldots, i_{m-1}\} \uplus \{i_m, \ldots, i_n\} = \{1, \ldots, n\} \\
&\ f(t_1, \ldots, t_n) \overset{x}{=} f(t'_1, \ldots, t'_m) \land C \mid S \mid \theta \rightarrow \\
&\ (t_1 \overset{x}{=} t'_1 \land \ldots \land t_{i_{m-1}} \overset{x}{=} t'_{m-1} \land f(t_{i_m}, \ldots, t_{n}) \overset{x}{=} t'_m) \land C \mid S \mid \theta \theta \sigma
\end{align*}
\]

where \( \sigma = \{x \mapsto f(x_1, \ldots, x_m)\} \), and \( x_1, \ldots, x_m \) are fresh variables.

Figure 10: Decomposition rule for an associative–commutative function symbol \( f \)

functions with no ordering among the arguments, an AC term can be represented by a canonical representative (Eker 2003; Hullot 1980) such that =$_{AC}$ is decidable.

The new decomposition rule for the AC case is similar to the decompose inference rule for associative function symbols, except that all permutations of \( f(t_1, \ldots, t_n) \) and \( f(s_1, \ldots, s_m) \) are considered. As before, the AC generalization of \( t \) and \( s \) are the maximal elements w.r.t. \(<_{AC}\) of the normal forms of \( t \overset{x}{=} t' \) w.r.t. the new extended generalization calculus. Just notice that this rule is (don’t know) non-deterministic, hence all possibilities must be explored.

Similarly to the rule \( \text{Decompose}_{A} \), we give the rule \( \text{Decompose}_{AC} \) for the case when, in the generalization problem \( f(t_1, \ldots, t_n) \overset{x}{=} f(s_1, \ldots, s_m) \), we have that \( n \geq m \). For the other way around, i.e., \( n < m \), a similar rule would be needed, that we omit since it is entirely similar. To simplify, we write \( \{i_1, \ldots, i_k\} \uplus \{i_{k+1}, \ldots, i_n\} = \{1, \ldots, n\} \) to denote that the sequence \( \{i_1, \ldots, i_n\} \) is a permutation of the sequence \( \{1, \ldots, n\} \) and, given an element \( k \in \{1, \ldots, n\} \), we split the sequence \( \{i_1, \ldots, i_n\} \) in the two parts, \( \{i_1, \ldots, i_k\} \) and \( \{i_{k+1}, \ldots, i_n\} \).

**Example 9.** Let \( t = f(a, f(a, b)) \) and \( s = f(f(b, b), a) \) be two terms where \( f \) is associative and commutative, i.e., \( ax(f) = \{A_f, C_f\} \). By applying the rules \( \text{Solve}_E \), \( \text{Recover}_E \), and \( \text{Decompose}_{AC} \) above, we end in two terminal configurations whose respective substitution components are \( \theta_1 = \{x \mapsto f(x_1, x_1, x_3), x_2 \mapsto x_1\} \) and \( \theta_2 = \{x \mapsto f(x_4, a, b), x_5 \mapsto a, x_6 \mapsto b\} \), thus we compute that the lgs modulo AC of \( t \) and \( s \) are \( f(x_1, x_1, x_3) \) and \( f(x_4, a, b) \). The corresponding computation trace is shown in Figure 11.

Termination is straightforward.

**Theorem 15 (Termination).** Given an equational theory \((\Sigma, E)\), \( \Sigma \)-terms \( t \) and \( t' \) such that every symbol in \( t \) and \( t' \) is free or associative-commutative, and \( x \) is a variable, every derivation stemming from an initial configuration \( \langle t \overset{x}{=} t' \mid \emptyset \mid id \rangle \) using the inference rules of Figures 6 and 10 terminates with a configuration \( \langle \emptyset \mid S \mid \theta \rangle \).

**Proof.** Similar to the proof of Theorem 1 [1].
In order to prove correctness and completeness of the lgg calculus modulo AC, similarly to Definitions 2, 9, and 10, we introduce the auxiliary concept of an associative-commutative conflict pair, and prove the appropriate auxiliary results.

First, we prove an auxiliary result stating that only (independently) fresh variables \( y \) appear in the index positions of the constraints in \( CT \) and \( S \) components of lgg configurations.

**Lemma 22 (Uniqueness of Generalization Variables).** Lemma 1 holds for \( x \sim x' \) when the symbols in \( t \), \( t' \) are free or associative-commutative, for the inference rules of Figures 9 and 10.

The lemma below states that the range of the substitutions partially computed at any stage of a generalization derivation coincides with the set of the index variables of the configuration.

**Lemma 23.** Given terms \( t \) and \( t' \) such that every symbol in \( t \) and \( t' \) is free or associative-commutative, and a fresh variable \( x \) such that \( \langle t \sim t' \mid \emptyset \mid \text{id} \rangle \rightarrow^* \langle CT \mid S \mid \theta \rangle \) using the inference rules of Figures 6 and 10, then \( \text{Index}(S \cup CT) \subseteq \text{Ran}(\theta) \), and \( \text{Ran}(\theta) = \text{Var}(x\theta) \).

**Proof.** Immediate by construction.

The following lemma establishes an auxiliary property that is useful for defining the notion of an associative-commutative conflict pair of terms.

**Lemma 24.** Given flattened terms \( t \) and \( t' \) such that every symbol in \( t \) and \( t' \) is free or associative-commutative, and a fresh variable \( x \), \( \langle t \sim t' \mid \emptyset \mid \text{id} \rangle \rightarrow^* \langle u \sim v \wedge CT \mid S \mid \theta \rangle \) using the inference rules of Figures 6 and 10, if there exist a position \( p \in \text{Pos}(t) \) and a position \( p' \in \text{Pos}(t') \) such that either:

1. \( t|_p = u, \ t'|_{p'} = v, \ \text{depth}(p) = \text{depth}(p') \), and \( \forall 1 \leq i \leq \text{depth}(p), \ \text{root}(t|_{p_i}) = \text{root}(t'|_{p'_{i}}) \); or
Definition 11 (Associative-commutative Conflict Pair). Given flattened terms $t$ and $t'$ such that every symbol in $t$ and $t'$ is free or associative-commutative, the pair $(u, v)$ is called an associative-commutative conflict of $t$ and $t'$ iff there exist at least one position $p$ or $p'$ in $t$ or $t'$ such that either:

1. $t|_p = u, v = f(v_1, ..., v_n), t'|_{p'} = f(w_1, ..., w_m), f$ is associative-commutative, for each $i \in \{1, ..., n\}$ there is $j \in \{1, ..., m\}$ s.t. $v_i =_E w_j$, depth$(p) = \text{depth}(p') + 1$, and $\forall 1 \leq i \leq \text{depth}(p')$, root$(t|_{p|_i}) = \text{root}(t'|_{p'|_i});$ or

2. $t|_p = u, v = f(v_1, ..., v_n), t'|_{p'} = f(w_1, ..., w_m), f$ is associative-commutative, for each $j \in \{1, ..., m\}$ there is $i \in \{1, ..., n\}$ s.t. $w_j =_E v_i$, depth$(p') = \text{depth}(p) + 1$, and $\forall 1 \leq i \leq \text{depth}(p), \text{root}(t|_{p|_i}) = \text{root}(t'|_{p'|_i}).$

Proof. Straightforward by successive application of the inference rules Decompose of Figure 10 and the inference rule Decompose$_{AC}$ of Figure 10.

Lemma 25. Given flattened terms $t$ and $t'$ such that every symbol in $t$ and $t'$ is free or associative-commutative, and a fresh variable $x$, $(t \triangleleft t' \mid \emptyset \mid \text{id}) \rightarrow^* \langle CT \mid u \triangleleft v \land S \mid \theta \rangle$ using the inference rules of Figures 6 and 10 iff $(u, v)$ is an associative-commutative conflict pair of $t$ and $t'$.

Proof. Similar to the proof of Lemma 20 but using Lemma 24 instead of Lemma 19 and Definition 11 instead of Definition 10.

The following lemma establishes the link between the computed substitution and a proper generalization term.

Lemma 26. Given flattened terms $t$ and $t'$ such that every symbol in $t$ and $t'$ is free or associative-commutative, and a fresh variable $x$, $(t \triangleleft t' \mid \emptyset \mid \text{id}) \rightarrow^* \langle C \mid S \mid \theta \rangle$ using the inference rules of Figures 7 and 10 iff $x \theta$ is a generalization of $t$ and $t'$ modulo associativity-commutativity.
\[ \text{Expand}_U \quad \text{root}(t) \equiv f \land U_f \in ax(f) \land \text{root}(t') \neq f \land t'' \in \{ f(e, t'), f(t', e) \} \]

\[ \langle t \equiv t' \land CT \mid S \mid \theta \rangle \rightarrow \langle t \equiv t'' \land CT \mid S \mid \theta \rangle \]

Figure 12: Inference rule for expanding function symbol \( f \) with identity element \( e \)

**Proof.** Similar to the proof of Lemma 21 but using Lemma 25 instead of Lemma 20 and Definition 11 instead of Definition 10.

Finally, correctness and completeness are proved as follows.

**Theorem 16 (Correctness and Completeness).** Given an equational theory \((\Sigma, E)\), flattened \( \Sigma \)-terms \( t \) and \( t' \) such that every symbol in \( t \) and \( t' \) is free or associative-commutative, and a fresh variable \( x \), then \( u \in \text{gen}_E(t, t') \) iff there is \( u' \in \{ x\theta \mid \langle t \equiv x \mid S \mid \theta \rangle \rightarrow^* \langle \emptyset \mid S \mid \theta \rangle \} \) using the inference rules of Figures 6 and 10 such that \( u \simeq_E u' \).

**Proof.** Similar to Theorem 12.

Recall that the inference rules of Figures 6 and 10 together are not confluent, so that different final configurations \( \langle \emptyset \mid S_1 \mid \theta_1 \rangle, \ldots, \langle \emptyset \mid S_n \mid \theta_n \rangle \) correspond to different generalizations \( x\theta_1, \ldots, x\theta_n \).

### 5.6. Least general generalization modulo \( U \)

Finally, let us introduce the inference rule of Figure 12 for handling function symbols \( f \) which have an identity element \( e \). This rule considers the identity axioms in a rather lazy or on-demand manner to avoid infinite generation of all the elements in the equivalence class. The rule corresponds to the case when the root symbol \( f \) of the term \( t \) in the left-hand side of the constraint \( t \equiv x \) has \( e \) as an identity element. A companion rule for handling the case when the root symbol \( f \) of the term \( t' \) in the right-hand side has \( e \) as an identity element is omitted, since that is entirely similar.

**Example 10.** Let \( t = f(a, b, c, d) \) and \( s = f(a, c) \) be two terms where \( ax(f) = \{ A_f, C_f, U_f \} \). By applying the rules Solve\( E \), Recover\( E \), Decompose\( AC \), and Expand\( U \) above, we end in a terminal configuration \( \langle \emptyset \mid S \mid \theta \rangle \), where \( \theta = \{ x \mapsto f(a, f(c, f(x_5, x_6))), x_1 \mapsto a, x_2 \mapsto f(c, f(x_5, x_6)), x_3 \mapsto c, x_4 \mapsto f(x_5, x_6) \} \), thus we compute that the lgg modulo \( ACU \) of \( t \) and \( s \) is \( f(a, c, x_5, x_6) \). The computation trace is shown in Figure 13.

Note that in the example above there is a unique lgg modulo \( U \), although this is not true for some generalization problems as witnessed by the following example.
\[ l_{\text{lgg}}(f(a, b, c, d), f(a, c)), \text{ with } E = \{C_1, A_1, U_1\} \]

\[ \downarrow \text{Initial Configuration} \]

\[ (f(a, b, c, d) \triangleq f(a, c) | \emptyset \mid \text{id}) \]

\[ \downarrow \text{Decompose}_{AC} \text{ (Other permutations are not shown)} \]

\[ (a \triangleq a \land f(b, c, d) \triangleq c | \emptyset | \{x \mapsto f(x_1, x_2)\}) \]

\[ \downarrow \text{Decompose} \]

\[ (f(b, c, d) \triangleq e | \emptyset | \{x \mapsto f(a(x_2), x_1 \rightarrow a)\}) \]

\[ \downarrow \text{Expand}_{U} \]

\[ \begin{align*}
& \left\{ e \triangleq c \land f(b, d) \triangleq e | \emptyset | \{x \mapsto f(a, f(x_3, x_4)), x_1 \rightarrow a, x_2 \rightarrow f(x_3, x_4)\} \right. \\
& \downarrow \text{Decompose} \\
& (f(b, d) \triangleq e | \emptyset | \{x \mapsto f(a, f(c, x_4)), x_1 \rightarrow a, x_2 \rightarrow f(c, x_4), x_3 \rightarrow c\}) \\
& \downarrow \text{Expand}_{U} \\
& \left. (f(b, d) \triangleq f(e, c) | \emptyset | \{x \mapsto f(a, f(c, x_4)), x_1 \rightarrow a, x_2 \rightarrow f(c, x_4), x_3 \rightarrow c\} \right)
\end{align*} \]

\[ \downarrow \text{Decompose}_{AC} \text{ (Other permutations are not shown)} \]

\[ (b \triangleq c \land d \triangleq c | \emptyset | \{x \mapsto f(a, f(c, f(x_3, x_6))), x_1 \rightarrow a, x_2 \rightarrow f(c, f(x_3, x_6)), x_3 \rightarrow c, x_4 \rightarrow f(x_5, x_6)\}) \]

\[ \downarrow \text{Solve} \]

\[ (a \triangleq e | b \triangleq c | \{x \mapsto f(a, f(c, f(x_5, x_6))), x_1 \rightarrow a, x_2 \rightarrow f(c, f(x_5, x_6)), x_3 \rightarrow c, x_4 \rightarrow f(x_5, x_6)\}) \]

\[ \downarrow \text{Solve} \]

\[ \emptyset | b \triangleq e \land d \triangleq e | \{x \mapsto f(a, f(c, f(x_5, x_6))), x_1 \rightarrow a, x_2 \rightarrow f(c, f(x_5, x_6)), x_3 \rightarrow c, x_4 \rightarrow f(x_5, x_6)\} \]

\[ \downarrow \text{maximal}_{ACU} \]

\[ \{x \mapsto f(a, f(c, f(x_5, x_6))), x_1 \rightarrow a, x_2 \rightarrow f(c, f(x_5, x_6)), x_3 \rightarrow c, x_4 \rightarrow f(x_5, x_6)\} \]

Figure 13: Computation trace for ACU–generalization of terms \(f(a, b, c, d)\) and \(f(a, c)\).

**Example 11.** Let \(t = f(f(a, a), f(b, a))\) and \(t' = f(f(b, b), a)\) be two terms such that \(\{A_1, U_1\} \subseteq ax(f)\). We end in two terminal configurations \(\emptyset | S_1 | \theta_1\) and \(\emptyset | S_2 | \theta_2\), where \(\theta_1 = \{x \mapsto f(f(x, x), f(y, a))\}\) and \(\theta_2 = \{x \mapsto f(y, f(b, a))\}\).

Both are more general terms.

Termination is slightly more difficult when there are symbols with identities.

**Theorem 17 (Termination).** Given an equational theory \((\Sigma, E)\), \(\Sigma\)-terms \(t\) and \(t'\) such that every symbol in \(t\) and \(t'\) is free or with identity element \(e\), and a fresh variable \(x\), every derivation stemming from an initial configuration \(\langle t \triangleq t' | \emptyset | \text{id} \rangle\) using the inference rules of Figures 6 and 12 terminates with a configuration \(\langle \emptyset | S | \theta \rangle\).

**Proof.** Let \(|u|\) be the number of symbol occurrences in the syntactic object \(u\). Let \(k\) be the minimum of \(|t|\) and \(|t'|\). \(k\) is an upper bound to the number of times that the inference rule Decompose\(_E\) of Figure 6 can be applied. Let \(\mathcal{K}\) be the maximum of \(|t|\) and \(|t'|\). Since the inference rule Expand\(_U\) adds a symbol \(f\) with an identity to one side of a constraint only when the other side already has such a symbol, \(\mathcal{K} - k\) is an upper bound to the number of times that the inference rule Expand\(_U\) followed by a decomposing rule of Figure 6 (or Figures 7, 8, and 10) can be applied. Finally, the application of rules Solve\(_E\)
and Recover$_E$ strictly decreases the size $|CT|$ of the CT component of the lgg configurations at each step, hence the derivation terminates.  

In order to prove correctness and completeness, we introduce the auxiliary concepts of an identity conflict pair, similarly to Definitions 2, 9, 10, and 11, plus some auxiliary results.

First, we prove an auxiliary result stating that only (independently) fresh variables $y$ appear in the index positions of the constraints in CT and S components of lgg configurations.

**Lemma 27 (Uniqueness of Generalization Variables).** Lemma 1 holds for $t \equiv t'$ when the symbols in $t$, $t'$ are free or with identity element $e$, for the inference rules of Figures 4 and 12.

The lemma below states that the range of the substitutions partially computed at any stage of a generalization derivation coincides with the set of the index variables of the configuration.

**Lemma 28.** Given terms $t$ and $t'$ such that every symbol in $t$ and $t'$ is free or with identity element $e$, and a fresh variable $x$ such that $\langle t \equiv t' | \emptyset | \text{id} \rangle \rightarrow^*$ $\langle CT | S | \theta \rangle$ using the inference rules of Figures 6 and 12, then Index($S \cup CT$) $\subseteq$ Ran($\theta$), and Ran($\theta$) = Var($x\theta$).

**Proof.** Immediate by construction.

The following lemma establishes an auxiliary property that is useful for defining the notion of an identity conflict pair of terms.

**Lemma 29.** Given terms $t$ and $t'$ such that every symbol in $t$ and $t'$ is free or with identity element $e$, and a fresh variable $x$, then $\langle t \equiv t' | \emptyset | \text{id} \rangle \rightarrow^*$ $\langle u \equiv v \lor CT | S | \theta \rangle$ using the inference rules of Figures 6 and 12 if and only if there exist a position $p \in \text{Pos}(t)$ and a position $p' \in \text{Pos}(t')$ such that either:

1. $t|_p = u$, $t'|_{p'} = v$, $\forall i \leq i \leq \min(\text{depth}(p), \text{depth}(p'))$, root($t|_{p|_i}$) = root($t'|_{p'|_i}$), and
   - if $p \geq p'$, then $\forall i \in \{\text{depth}(p'), \ldots, \text{depth}(p)\}$, root($t|_{p|_i}$) = $f$ s.t. $f$ has identity element $e$; or
   - if $p' > p$, then $\forall i \in \{\text{depth}(p), \ldots, \text{depth}(p')\}$, root($t'|_{p'|_i}$) = $f$ s.t. $f$ has identity element $e$; or
2. $t|_p = u$, $v = e$, $p' = p|_{\text{depth}(p)-1}$, root($t|_{p'}$) = $f$ s.t. $f$ has identity element $e$; and $\forall i \leq i \leq \text{depth}(p')$, root($t|_{p'|_i}$) = root($t'|_{p'|_i}$); or
3. $u = e$, $t'|_{p'} = v$, $p = p|_{\text{depth}(p')-1}$, root($t'|_p$) = $f$ s.t. $f$ has identity element $e$, and $\forall i \leq i \leq \text{depth}(p)$, root($t|_{p|_i}$) = root($t'|_{p'|_i}$).

**Proof.** Straightforward by successive application of the inference rule Decompose of Figure 11 and the inference rule Decompose$_U$ of Figure 12.
Definition 12 (Identity Conflict Pair). Given terms \( t \) and \( t' \) such that every symbol in \( t \) and \( t' \) is free or with identity element \( e \), the pair \((u, v)\) is called an identity conflict pair of \( t \) and \( t' \) iff there exist at least one position \( p \in \text{Pos}(t) \) and at least one position \( p' \in \text{Pos}(t') \) such that either:

1. \( t|_p = u, t'|_{p'} = v, u \neq E v, \forall i \leq \min(\text{depth}(p), \text{depth}(p')), \text{root}(t|_{p|_i}) = \text{root}(t'|_{p'|_i}) \), and
   - if \( p \geq p' \), then \( \forall i \in \{\text{depth}(p'), \ldots, \text{depth}(p)\} \), \( \text{root}(t|_{p|_i}) = f \) s.t. \( f \) has identity element \( e \); or
   - if \( p' > p \), then \( \forall i \in \{\text{depth}(p), \ldots, \text{depth}(p')\} \), \( \text{root}(t'|_{p'|_i}) = f \) s.t. \( f \) has identity element \( e \); or
2. \( t|_p = u, v = e, u \neq E e, p' = p|_{\text{depth}(p) - 1}, \text{root}(t|_{p'}) = f \) s.t. \( f \) has identity element \( e \), and \( \forall 1 \leq i \leq \text{depth}(p') \), \( \text{root}(t|_{p'|_i}) = \text{root}(t'|_{p'|_i}) \); or
3. \( u = e, t'|_{p'} = v, v \neq E e, p = p|_{\text{depth}(p) - 1}, \text{root}(t'|_p) = f \) s.t. \( f \) has identity element \( e \), and \( \forall 1 \leq i \leq \text{depth}(p) \), \( \text{root}(t|_{p|_i}) = \text{root}(t'|_{p'|_i}) \).

The following lemma states the appropriate connection between the constraints in a derivation and the identity conflict pairs of the initial configuration.

Lemma 30. Given terms \( t \) and \( t' \) such that every symbol in \( t \) and \( t' \) is free or has an identity element, and a fresh variable \( x \), \( \langle t \triangle u \ | \ \emptyset \ | \ \text{id} \rangle \rightarrow^* \langle C \ | \ S | \ \theta \rangle \) using the inference rules of Figures 6 and 12 iff \((u, v)\) is an identity conflict pair of \( t \) and \( t' \).

Proof. Similar to the proof of Lemma 20 but using Lemma 29 instead of Lemma 19 and Definition 12 instead of Definition 10.

The following lemma establishes the link between the computed substitution and a proper generalization term.

Lemma 31. Given terms \( t \) and \( t' \) such that every symbol in \( t \) and \( t' \) is free or has an identity element, and a fresh variable \( x \), \( \langle t \triangle u \ | \ \emptyset \ | \ \text{id} \rangle \rightarrow^* \langle C \ | \ S | \ \theta \rangle \), using the inference rules of Figures 6 and 12 iff \( x\theta \) is a generalization of \( t \) and \( t' \) modulo identity.

Proof. Similar to the proof of Lemma 21 but using Lemma 30 instead of Lemma 20 and Definition 12 instead of Definition 10.

Finally, correctness and completeness are proved as follows.

Theorem 18 (Correctness and Completeness). Given an equational theory \( (\Sigma, E) \), \( \Sigma \)-terms \( t \) and \( t' \) such that every symbol in \( t \) and \( t' \) is free or has an identity element, and a fresh variable \( x \), then \( u \in \text{gen}_E(t, t') \) iff there is \( u' \) in \( \{x\theta \ | \ \langle t \triangle u' \ | \ \emptyset \ | \ \text{id} \rangle \rightarrow^* (\emptyset \ | \ S | \ \theta)\} \) using the inference rules of Figures 6 and 12 such that \( u \simeq_E u' \).
Proof. Similar to Theorem 12.

Recall that the inference rules of Figures 6 and Figure 12 together are not confluent, hence different final configurations \( \langle \emptyset \mid S_1 \mid \theta_1 \rangle, \ldots, \langle \emptyset \mid S_n \mid \theta_n \rangle \) correspond to different generalizations \( x\theta_1, \ldots, x\theta_n \). Note that if the symbol \( f \) has an identity element \( e \) and is commutative or associative-commutative, then it is not necessary to consider both forms \( f(t', e) \) and \( f(e, t') \) in Figure 12.

5.7. A general ACU-generalization method

For the general case when different function symbols satisfying different associativity and/or commutativity and/or identity axioms are considered, we can use the inference rules above all together (inference rules of Figures 6, 7, 8, 10, and 12) with no need whatsoever for any changes or adaptations.

The key property of all the above inference rules is their locality: they are local to the given top function symbol in the left term (or right term in some cases) of the constraint they are acting upon, irrespective of what other function symbols and what other axioms may be present in the given signature \( \Sigma \) and theory \( E \). Such a locality means that these rules are modular, in the sense that they do not need to be changed or modified when new function symbols are added to the signature and new \( A \), and/or \( C \), and/or \( U \) axioms are added to \( E \). However, when new axioms are added to \( E \), some rules that applied before (for example decomposition for an \( f \) which before satisfied \( ax(f) = \emptyset \), but now has \( ax(f) \neq \emptyset \)) may not apply, and, conversely, some rules that did not apply before now may apply (because new axioms are added to \( f \)). But the rules themselves do not change! They are the same and can be used to compute the set of lgs of two terms modulo any theory \( E \) in the parametric family \( IE \) of theories of the form \( E = \bigcup_{f \in \Sigma} ax(f) \), where \( ax(f) \subseteq \{ A_f, C_f, U_f \} \). Termination of the algorithm is straightforward.

Theorem 19 (Termination). For an equational theory \((\Sigma, E)\) with \( E \in IE \), two \( \Sigma \)-terms \( t \) and \( t' \), and a fresh variable \( x \), every derivation stemming from an initial configuration \( \langle t \overset{x}{\equiv} t' \mid \emptyset \mid id \rangle \) using the inference rules of Figures 6, 7, 8, 10, and 12 terminates with a configuration \( \langle \emptyset \mid S \mid \theta \rangle \).

The correctness and completeness of our algorithm is ensured by:

Theorem 20 (Correctness and Completeness). Given an equational theory \((\Sigma, E)\) with \( E \in IE \), \( \Sigma \)-terms \( t \) and \( t' \), and a fresh variable \( x \), then \( u \in gen_E(t, t') \) iff there is \( u' \) in \( \{ x\theta \mid (t \overset{x}{\equiv} t' \mid \emptyset \mid id) \rightarrow^* (\emptyset \mid S \mid \theta) \} \) using the inference rules of Figures 6, 7, 8, 10, and 12 such that \( u \simeq_E u' \).

6. Order-Sorted Least General Generalizations modulo \( E \)

In this section, we generalize the unsorted modular equational generalization algorithm presented in Section 5 to the order-sorted setting.
Decompose \( f \in (\Sigma \cup \mathcal{X}) \land ax(f) = \emptyset \land f : [s_1] \times \ldots \times [s_n] \rightarrow [s] \)
\[
\langle f(t_1, \ldots, t_n) \rangle \triangleq f(t_1', \ldots, t_n') \land CT \mid S \mid \theta \rightarrow
\langle t_1\ [s_1] \rangle \triangleq t_1' \land \ldots \land t_n\ [s_n] \triangleq t_n' \land CT \mid S \mid \theta \sigma
\]
where \( \sigma = \{ x: [s] \rightarrow f(x_1:[s_1], \ldots, x_n:[s_n]) \} \), \( x_1:[s_1], \ldots, x_n:[s_n] \) are fresh variables, and \( n \geq 0 \)

Solve \( f = \text{root}(t) \land g = \text{root}(t') \land f \neq g \land U_f \not\in ax(f) \land U_g \not\in ax(g) \land \)
\[
\langle t \triangleq t' \land CT \mid S \mid \theta \rangle \rightarrow \langle CT \mid S \land t \triangleq t' \mid \theta \rangle
\]
where \( \sigma = \{ x: [s] \mapsto z:s' \} \) and \( z:s' \) is a fresh variable.

Recover \( \)
\[
\langle t \not\triangleq \text{root}(t') \land \exists y : t \triangleq t' \in^E S \rightarrow \langle CT \mid S \mid \theta \rangle \rightarrow \langle CT \mid S \mid \theta \sigma \rangle
\]
where \( \sigma = \{ x: [s] \mapsto y.s' \} \)

Figure 14: Basic inference rules for least general \( E \)-generalization

First of all, we assume that a kind-completed, pre-regular, order-sorted signature \( (\Sigma, S, <) \) has the same equational attributes for overloaded symbols, i.e., for any two operator declarations of symbol \( f \) with arity \( n \), \( f : s_1 \times \ldots \times s_n \rightarrow s \) and \( f : s'_1 \times \ldots \times s'_n \rightarrow s' \) such that \( s_i \leq s_i \) for \( 1 \leq i \leq n \), if an equation \( t = t' \) is applicable to \( f : s_1 \times \ldots \times s_n \rightarrow s \), it must also be applicable to \( f : s'_1 \times \ldots \times s'_n \rightarrow s' \).

As in Section 4, we consider two terms \( t \) and \( t' \) having the same top sort, otherwise they are incomparable and no generalization exists. Starting from the initial configuration \( \langle t \triangleq t' \mid \emptyset \mid id \rangle \) where \( [s] = [LS(t)] = [LS(t')] \), configurations are transformed until a terminal configuration \( \langle \emptyset \mid S \mid \theta \rangle \) is reached. Also, as in Section 5, when different function symbols satisfying different associativity and/or commutativity and/or identity axioms are considered, we can use the inference rules of Figures 11, 15, 16, 17 and 18 all together.

Note that we have just followed the same approach of Section 4 and extended the inference rules of Figures 6, 7, 8, 10 and 12 to Figures 14, 15, 16, 17 and 18 provided below.

Termination is straightforward.

**Theorem 21 (Termination).** Given a kind-completed, pre-regular, order-sorted equational theory \( (\Sigma, E) \) with the same equational attributes for overloaded symbols, terms \( t \) and \( t' \), and a fresh variable \( x \), every derivation stemming from an initial configuration \( \langle x : t \triangleq t' \mid \emptyset \mid id \rangle \) using the inference rules of Figures 14, 15
Decompose$_C$

\[ f : [s] \times [s] \rightarrow [s] \land C_f \in ax(f) \land A_f \notin ax(f) \land i \in \{1, 2\} \]

\[ \langle f(t_1, t_2) \rangle_{x:\{s\}} \triangleq f(t'_1, t'_2) \land CT \mid S \mid \theta \]

\[ \rightarrow \langle f(t_1, \ldots, t_n) \rangle_{x:\{s\}} \triangleq f(t'_{i+1}, \ldots, t'_n) \land CT \mid S \mid \theta \sigma \]

where \( \sigma = \{x:s \mapsto f(x_1:s, x_2:s)\} \), and \( x_1:s, x_2:s \) are fresh variables.

Figure 15: Decomposition rule for a commutative function symbol \( f \)

Decompose$_A$

\[ f : [s] \times [s] \rightarrow [s] \land A_f \in ax(f) \land C_f \notin ax(f) \land m \geq 2 \land n \geq m \land k \in \{1, \ldots, (n - m) + 1\} \]

\[ \langle f(t_1, \ldots, t_n) \rangle_{x:\{s\}} \triangleq f(t'_{i+1}, \ldots, t'_n) \land CT \mid S \mid \theta \]

\[ \rightarrow \langle f(t_1, \ldots, t_k) \rangle_{x:\{s\}} \triangleq t'_1 \land f(t_{k+1}, \ldots, t_n) \triangleq f(t'_{2}, \ldots, t'_n) \land CT \mid S \mid \theta \sigma \]

where \( \sigma = \{x:s \mapsto f(x_1:s, x_2:s)\} \), and \( x_1:s, x_2:s \) are fresh variables.

Figure 16: Decomposition rule for an associative (non-commutative) function symbol \( f \)

16, 17, and 18 terminates with a configuration \( \emptyset \mid S \mid \theta \).

Proof. Similar to the proofs of Theorems 1 and 17.

In order to prove correctness and completeness, Definitions 9, 10, 11, and 12 for \( E \)-conflict pairs are extended to the order-sorted case in the obvious way; recall that variables with the same name but different sorts, e.g. \( x:A \) and \( x:B \), are considered as different variables.

We follow the same proof schema of Section 4.2 and define order-sorted \( E \)-lggs computation by subsort specialization. That is, to compute generalizations by removing sorts (i.e., upgrading variables to top sorts), computing (unsorted) \( E \)-lggs, and then obtaining the right subsorts by a suitable post-processing. This approach is not used in practice, it is used only for the proofs of correctness and completeness of the inference rules.

First, for generalization in the modulo case, we introduce a special notation for subterm replacement when we have associative or associative-commutative conflict pairs.

Definition 13 (A-SubTerm Replacement). Given two flattened terms \( t \) and \( t' \) and an associative conflict pair \((u, v)\) with conflict positions \( p \in \text{Pos}(t) \) and \( p' \in \text{Pos}(t') \) such that \( t_p = u, v = f(v_1, \ldots, v_n), t'_{p'} = f(w_1, \ldots, w_m, v_1, \ldots, v_n, w'_1, \ldots, w'_m), \) and \( f \) is associative, we write \( t[x:s]_p \) and \( t'[x:s]_{p'} \) to denote the terms \( (t'[x:s]_{p'}) \).
Decompose\textsubscript{AC}

\[
f : \{s \times [s] \rightarrow [s] \wedge \{A_f, C_f\} \subseteq ax(f) \wedge n \geq m \wedge \{i_1, \ldots, i_{m - 1}\} \cap \{i_m, \ldots, i_n\} = \{1, \ldots, n\}\]
\[
\langle f(t_1, \ldots, t_n) \rangle^x_{[s]} \triangleq f(t'_1, \ldots, t'_{m}) \wedge C \mid S \mid \theta \rangle
\]
\[
\rightarrow \langle t_{i_1} \triangleq t'_1 \wedge \ldots \wedge t_{i_{m - 1}} \triangleq t'_{m - 1} \wedge f(t_{i_m}, \ldots, t_{i_n}) \triangleq t'_{m} \wedge C \mid S \mid \theta \sigma \rangle
\]

where \(\sigma = \{x[s] \mapsto f(x_1[s], \ldots, x_m[s])\}\), and \(x_1[s], \ldots, x_m[s]\) are fresh variables.

Figure 17: Decomposition rule for an associative–commutative function symbol \(f\)

\[
\text{Expand}_{U}
\]
\[
f : \{s \times [s] \rightarrow [s] \wedge U \in ax(f) \wedge root(t) \equiv f \wedge root(s) \neq f \wedge t'' \in \{f(e, t'), f(t', e)\}\]
\[
\langle t \triangleq t' \wedge CT \mid S \mid \theta \rangle \rightarrow \langle t \triangleq t'' \wedge CT \mid S \mid \theta \rangle
\]

Figure 18: Inference rule for expanding function symbol \(f\) with identity element \(e\)

**Definition 14 (AC-Subterm Replacement).** Given two flattened terms \(t\) and \(t'\) and an associative-commutative conflict pair \((u, v)\) with conflict positions \(p \in \text{Pos}(t)\) and \(p' \in \text{Pos}(t')\) such that \(t|_p = u, v = f(v_1, \ldots, v_n), t'|_{p'} = f(w_1, \ldots, w_m), f\) is associative-commutative, for each \(i \in \{1, \ldots, n\}\) there is \(j \in \{1, \ldots, m\}\) s.t. \(v_i = \bar{w}_j, we write \(t[[x:s]]_p = t[x:s]_p\) and \(t'||[x:s]|_{p'} = t'[f(w_1', \ldots, w_k', x:s)]_{p'}\) to denote the terms \(t[[x:s]]_p = t[x:s]_p\) and \(t'||[x:s]|_{p'} = t'[f(w_1', \ldots, w_k', x:s)]_{p'}\) where \(\{w_1', \ldots, w_k'\} = \{w \in \{w_1, \ldots, w_m\} \mid \exists i \in \{1, \ldots, n\}, w = \bar{v}_i\}\).

As in Section 4.2, we define order-sorted \(E\)-lgg computation by subsort specialization using a top-sorted generalization (see Definition 6) and a sort-specialized generalization (see Definition 16).

**Definition 15 (Top-sorted Equational Generalization).** Given a kind, completed, pre-regular, order-sorted equational theory \((\Sigma, E)\) with the same equational attributes for overloaded symbols, and flattened \(\Sigma\)-terms \(t\) and \(t'\) such that \([LS(t)] = [LS(t')], let (u_1, v_1), \ldots, (u_k, v_k)\) be the \(E\)-conflict pairs of \(t\) and \(t'\), and for each such conflict pair \((u_i, v_i)\), let \((p_1', \ldots, p_{n_{i'}}), q_1', \ldots, q_{n_{i'}}\) be the corresponding \(E\)-conflict positions, and let \(s_i = [LS(u_i)] = [LS(v_i)]\). We define the term denoting the top order-sorted equational least general generalization as

\[
tsg_E(t, t') = ((t|[x_1:s_1]|_{p_1', \ldots, p_{n_{i'}}, q_1', \ldots, q_{n_{i'}}} \cdots )|[x_k:s_k]|_{p_{n_k}} \cdots )\]

where \(x_1:s_1, \ldots, x_k:s_k\) are fresh variables.

The order-sorted equational \(E\)-lgg’s are obtained by subsort specialization.
Definition 16 (Sort-specialized Equational Generalization). Given a kind-completed, pre-regular, order-sorted equational theory \((\Sigma, E)\) with the same equational attributes for overloaded symbols, and flattened \(\Sigma\)-terms \(t\) and \(t'\) such that \([LS(t)] = [LS(t')]\), let \((u_1, v_1), \ldots, (u_k, v_k)\) be the conflict pairs of \(t\) and \(t'\). We define

\[
\text{sort-down-subs}_E(t, t') = \{ \rho \mid \text{Dom}(\rho) = \{x_1; s_1, \ldots, x_k; s_k\} \land \\
\forall 1 \leq i \leq k, \rho(x_i; s_i) = x_i; s_i' \land s_i' \in \text{LUBS}(LS(u_i), LS(v_i)) \}\]

where all the \(x_i; s_i'\) are fresh variables. The set of sort-specialized \(E\)-generalizations is defined as \(\text{ssg}_E(t, t') = \{ tsg_E(t, t')\rho \mid \rho \in \text{sort-down-subs}_E(t, t') \}\).

Now, we prove that sort-specialized \(E\)-generalizations are the same as order-sorted \(E\)-lggs.

**Theorem 22.** Given a kind-completed, pre-regular, order-sorted equational theory \((\Sigma, E)\) with the same equational attributes for overloaded symbols, and flattened \(\Sigma\)-terms \(t\) and \(t'\) such that \([LS(t)] = [LS(t')]\), \(tsg_E(t, t')\) is an order-sorted equational generalization of \(t\) and \(t'\), and \(\text{lgg}_E(t, t')\) provides a minimal complete set of order-sorted equational lggs.

**Proof.** Similar to the proof of Theorem 6. \(\square\)

Finally, we prove the correctness and completeness of the order-sorted, equational generalization algorithm.

**Theorem 23 (Correctness and Completeness).** Given a kind-completed, pre-regular, order-sorted equational theory \((\Sigma, E)\) with the same equational attributes for overloaded symbols, flattened \(\Sigma\)-terms \(t\) and \(t'\) such that \([s] = [LS(t)] = [LS(t')]\), and a fresh variable \(x; s\), \(u \in \text{lgg}_E(t, t')\) is an order-sorted equational lgg of \(t\) and \(t'\) iff \((t \not\equiv t' | \emptyset | \text{id}) \rightarrow^* (\emptyset | S | \emptyset)\) using the inference rules of Figures 14, 15, 16, 17, and 18 for some \(S\) and \(\emptyset\) and \(u \simeq_E (x; s)\).

**Proof.** Similar to the proof of Theorem 7. \(\square\)

7. Implementation

The different calculi proposed in this paper have been implemented in the high-performance, rewriting logic language Maude (Clavel et al., 2007). The whole implementation consists of about 700 lines of Maude code, and relies on Maude’s powerful reflective capabilities to obtain a straightforward translation of the inference system presented in this paper.

First, the module that contains the considered order-sorted theory\(^1\) and the input terms are lifted to the meta-level, and an initial configuration is constructed. Then, an exhaustive search is conducted by using Maude’s metaSearch.
function, which executes the inference rules in the calculi described above as meta-level rewrite rules in order to obtain the complete set of least general generalizations. Since the computed set is not minimal, a final filtering step is performed that allows us to get rid of those elements that do not satisfy the maximality property given in Definition 8. This is done by pairwise comparison of all elements in the set using the ordering $<_E$, discarding any term $u$ that subsumes modulo $E$ any other term $v$ in the set, i.e., $u <_E v$. We use Maude’s metaMatch for this task, since it provides a simple and efficient means to check the relation $<_E$.

Finally, in order to improve the efficiency of the algorithm without compromising its correctness, we implement the AC decomposition process by using a next-permutation routine that is inspired in C++’s STL, rather than carrying out a simpler, naïve generation of all permutations. The generation of unique permutations exponentially reduces the cost of permuting the arguments, which drastically improves performance for the case of heavily repeated subterms.

The front-end of the implementation is a new Full Maude function, get lggs, which is publicly available at [http://www.dsic.upv.es/grupos/elp/FMlgg.html](http://www.dsic.upv.es/grupos/elp/FMlgg.html) For instance, consider the following Full Maude module (we refer the reader to [Clavel et al., 2007](#) for Maude and Full Maude syntax):

```maude
(mod fACU-OS is
  sorts E A B C D Empty .
  subsort Empty < A B .
  subsort A < C D .
  subsort B < C D .
  subsort C < E .
  subsort D < E .
  op a : -> A .
  op b : -> B .
  op c : -> C .
  op d : -> D .
  op e : -> Empty .
  op f : Empty Empty -> Empty [assoc comm id: e] .
  op f : E E -> E [assoc comm id: e] .
endm)
```

This module is automatically extended to its kind-complete version by Maude. It defines five constants $a$, $b$, $c$, $d$, $e$ and four binary symbols sharing the same name $f$ but with different signatures corresponding to the subsort structure of Figure 5. All four versions of symbol $f$ (plus its kind extension $f : [E] \rightarrow [E]$) are associative-commutative and with identity symbol the constant $e$. Now, we can type the following generalization problem in Full Maude obtaining the six possible order-sorted $E$-lggs.

```maude
(get lggs in fACU-OS : f(b,b,a) =? f(a,a,b) .)
```

48
Lgg 1  
\( f(X_1:C,b,a) \)

Lgg 2  
\( f(X_1:D,b,a) \)

Lgg 3  
\( f(X_1:C,X_1:C,X_3:C) \)

Lgg 4  
\( f(X_1:C,X_1:C,X_3:D) \)

Lgg 5  
\( f(X_1:D,X_1:D,X_3:C) \)

Lgg 6  
\( f(X_1:D,X_1:D,X_3:D) \)

No more lgg.

We have also made available a meta-level function `metaGeneralize` which is useful for tools using generalization.

Additionally, a web-based facility for running the tool is available at [http://www dsic upv es grupos elp weblgg html](http://www dsic upv es grupos elp weblgg html). Figure [19](#) shows a screen capture for the E-lggs of terms \( f(b,b,a) \) and \( f(a,a,b) \) without sort information.

8. Conclusion and Future Work

We have presented an order-sorted, modular equational generalization algorithm that computes a minimal and complete set of least general generalizations for two terms modulo any combination of associativity, commutativity and identity axioms for the binary symbols in the theory. Our algorithm is directly applicable to any many-sorted and order-sorted declarative language and equational reasoning system (and also, a fortiori, to untyped languages and systems which have only one sort). As shown in the examples, the algorithms we propose are effective to compute \( E \)-generalizations, which would be unfeasible in a naïve way.

In our own work, we plan to use the proposed order-sorted equational generalization algorithm as a key component of a narrowing-based partial evaluator (PE) for programs in order-sorted rule-based languages such as OBJ, CafeOBJ, and Maude. This will make available for such languages useful narrowing-driven PE techniques developed for the untyped setting in, e.g., [Albert et al., 1999; Alpuente et al., 1998a,b, 1999]. We are also considering adding this generalization mechanism to an inductive theorem prover such a Maude’s ITP ([Clavel and Palomino, 2005]) to support automatic conjecture of lemmas. This will provide a typed analogue of similar automatic lemma conjecture mechanisms in untyped inductive theorem provers such as Nqthm ([Boyer and Moore, 1980b]) and its ACL2 successor ([Kaufmann et al., 2000a]).
Acknowledgements

We gratefully acknowledge Pedro Ojeda for initial implementations of the order-sorted and equational generalization algorithms. We are also thankful to Hassan Aït-Kaci and Temur Kutsia for useful remarks on (Alpuente et al., 2009a,b).
