Type	Article scientifique dans une revue à comité de lecture
Année	2013
Langue	Anglais
Date	Août 2013
Numéro	3
Pagination	683-694
Volume	199
Titre de la revue	New Phytologist
ISSN	1469-8137
Mots-clés	aminopeptidase [9], carboxypeptidase [10], leaf senescence [11], nitrate availability [12], nitrogen remobilization [13], selective autophagy [14]

Autophagy is present at a basal level in all plant tissues and is induced during leaf ageing and in response to nitrogen (N) starvation. Nitrogen remobilization from the rosette to the seeds is impaired in autophagy mutants. This report focuses on the role of autophagy in leaf N management and proteolysis during plant ageing. Metabolites, enzyme activities and protein contents were monitored in several autophagy-defective (*atg*) Arabidopsis mutants grown under low and high nitrate conditions.

Results showed that carbon (C) and N statuses were affected in *atg* mutants before any senescence symptoms appeared. *atg* mutants accumulated larger amounts of ammonium, amino acids and proteins than wild type, and were depleted in sugars. Over-accumulation of proteins in *atg* mutants was selective and occurred despite higher endopeptidase and carboxypeptidase activities. Specific over-accumulation of the ribosomal proteins S6 and L13 subunits, and of catalase and glutamate dehydrogenase proteins was observed. *atg* mutants also accumulated peptides putatively identified as degradation products of the Rubisco large subunit and glutamine synthetase 2 (GS2). Incomplete chloroplast protein degradation resulting from autophagy defects could explain the higher N concentrations measured in *atg* rosettes and defects in N remobilization.

It is concluded that autophagy controls C : N status and protein content in leaves of Arabidopsis.
