January 28, 2010

Abstract

This paper presents a new nonlinear dyadic subdivision scheme eliminating the Gibbs oscillations close to discontinuities. Its convergence, stability and order of approximation are analyzed. It is proved that this scheme converges towards limit functions Hölder continuous with exponent larger than 1.299. Numerical estimates provide a Hölder exponent of 2.438. This subdivision scheme is the first one that simultaneously achieves the control of the Gibbs phenomenon and has limit functions with Hölder exponent larger than 1.

Key Words. Nonlinear subdivision scheme, limit function, regularity, stability, Gibbs phenomenon.

1 Introduction

Subdivision schemes are useful tools for generating smooth curves and surfaces. For convergent schemes, starting from discrete sets of control points...
and using basic rules of low complexity, curves or surfaces can be obtained as
limits (called limit functions) of sequences of points generated by recursive
application of the subdivision scheme.

A simple example of a subdivision scheme is the family of interpo-
latory subdivision schemes, based on local Lagrange’s interpolation that has
been derived and analyzed in [11]. Another example is the family of spline
subdivision schemes related to spline spaces [8].

The four-point interpolatory scheme [16], [15], is a convergent linear
scheme of the first family, involving four-point stencils at each subdivision,
for which the limit functions are at least in the space $C^2$ (see definitions
1 and 2 in Section 3). The Chaikin algorithm [7] is an example of a spline
subdivision scheme, with lower complexity than the previous example and
converging towards $C^2$ functions.

For applications, for instance to computer-aided geometric design or ima-
ge processing, complexity and convergence/regularity are not the only qua-
ity criteria. On the one hand, the order of approximation, which charac-
terizes the precision of the scheme, is crucial. On the other hand, oscillations
that could occur in the limit functions in the vicinity of strongly varying
data (coming from the sampling of discontinuous functions), called Gibbs
oscillations, are undesirable.

In the last decade, various attempts to improve the properties of linear
subdivision schemes have lead to nonlinear subdivision schemes. For such
schemes, the subdivision rules become data dependant; in addition to the
previously defined criteria, a stability property should be added to ensure
that the nonlinear scheme is linearly affected by perturbations of the data
(for linear schemes, the stability is a direct consequence of the convergence).

For nonlinear subdivision schemes, few general results of convergence or
stability are available; see for instance [5], [9], [12], [22], [10], [19] and [17].

A large family of nonlinear subdivision schemes comprising e.g. ENO,
WENO or PPH schemes [9], [4], is built from schemes constructed as a
perturbation of the four-point linear interpolatory $C^2$- Lagrange scheme
based on centered degree 3 polynomial interpolation. These schemes are
interpolatory subdivision schemes and are constructed to avoid the Gibbs
oscillations occurring classically for linear interpolatory schemes (see Figure
1 in Section 6). The schemes of this family are unfortunately characterized
by a low regularity of the limit functions, typically $C^{1-}$. Moreover, the ENO
scheme is unstable.

In [14], a new linear and non-interpolatory four-point subdivision scheme
has been presented. Its refinement rule is based on local cubic interpolation
followed by a shift of $1/4$ or, in other words, an evaluation at positions
1/4 and 3/4 rather than the standard evaluation at 1/2 that leads to the interpolatory scheme. This new scheme has been shown to be convergent towards a $C^2$ curve.

The aim of this paper is to analyze a new scheme formulated using the same trick (shift of 1/4) for the PPH-type schemes [4] which are derived by modifying the classical four-point interpolatory subdivision scheme substituting the arithmetic mean with the harmonic mean (see formula 2 in Section 2). After the definition of the scheme in Section 2 we successively analyze its convergence (Section 3), its stability (Section 4) and its order of approximation (in Section 5). Its behavior in presence of strongly varying data (Gibbs oscillations) is analyzed in Section 6. The last section is devoted to concluding remarks.

2 A new nonlinear subdivision scheme

As mentioned above, the starting point of our work is the construction of N. Dyn, M.S. Floater and K. Hormann in [14]. There, a new linear and non-interpolatory four-point dyadic subdivision scheme that generates $C^2$ curves is presented. Its refinement rule is based on the local cubic Lagrange interpolation based on the values $\{f_{n-1}, f_n, f_{n+1}, f_{n+2}\}$ at the positions $\{-1, 0, 1, 2\}$ followed by an evaluation at positions 1/4 and 3/4. For all $f \in \mathcal{C}^\infty(\mathbb{Z})$, the scheme is then given by

\[
(Sf)_{2n} = -\frac{7}{128}f_{n-1} + \frac{105}{128}f_n + \frac{35}{128}f_{n+1} - \frac{5}{128}f_{n+2},
\]

\[
(Sf)_{2n+1} = -\frac{5}{128}f_{n-1} + \frac{35}{128}f_n + \frac{105}{128}f_{n+1} - \frac{7}{128}f_{n+2}.
\]

(1)

Following [4] where a nonlinear scheme is derived by modifying the classical four-point interpolatory subdivision scheme substituting the harmonic mean for the arithmetic mean, we first obtain two new formulations of the scheme (1).

1

\[
(Sf)_{2n} = \frac{49}{64}f_n + \frac{14}{64}f_{n+1} + \frac{1}{64}f_{n+2} - \frac{7}{64} \frac{(d^2f_n + d^2f_{n+1})}{2},
\]

\[
(Sf)_{2n+1} = \frac{15}{64}f_n + \frac{50}{64}f_{n+1} - \frac{1}{64}f_{n+2} - \frac{5}{64} \frac{(d^2f_n + d^2f_{n+1})}{2}.
\]

2

\[
(Sf)_{2n} = -\frac{1}{64}f_{n-1} + \frac{50}{64}f_n + \frac{15}{64}f_{n+1} - \frac{5}{64} \frac{(d^2f_n + d^2f_{n+1})}{2},
\]
\[(Sf)_{2n+1} = \frac{1}{64} f_{n-1} + \frac{14}{64} f_n + \frac{49}{64} f_{n+1} - \frac{7}{64} (d^2 f_n + d^2 f_{n+1}) / 2,\]

where \((d^2 f_n)\), the second order difference, is defined by \(d^2 f_n = f_{n+1} - 2f_n + f_{n-1}\).

The two formulations differ essentially in the points \(f_k, n-1 \leq k \leq n+2\) contributing to the first three components of the right-hand side of 1 and 2.

Using the same strategy as in [4], we define the new nonlinear subdivision scheme \(S_{PPHA}\) associated to (1) by

1. If \(|d^2 f_n| \geq |d^2 f_{n+1}|\),
   \[
   (S_{PPHA} f)_{2n} = \frac{49}{64} f_n + \frac{14}{64} f_{n+1} + \frac{1}{64} f_{n+2} - \frac{7}{64} \text{pph}(d^2 f_n, d^2 f_{n+1}),
   \]
   \[
   (S_{PPHA} f)_{2n+1} = \frac{15}{64} f_n + \frac{50}{64} f_{n+1} - \frac{1}{64} f_{n+2} - \frac{5}{64} \text{pph}(d^2 f_n, d^2 f_{n+1}),
   \]

and if \(|d^2 f_n| < |d^2 f_{n+1}|\),

1. \[
   (S_{PPHA} f)_{2n} = -\frac{1}{64} f_{n-1} + \frac{50}{64} f_n + \frac{15}{64} f_{n+1} - \frac{5}{64} \text{pph}(d^2 f_n, d^2 f_{n+1}),
   \]
   \[
   (S_{PPHA} f)_{2n+1} = \frac{1}{64} f_{n-1} + \frac{14}{64} f_n + \frac{49}{64} f_{n+1} - \frac{7}{64} \text{pph}(d^2 f_n, d^2 f_{n+1}),
   \]

where \(\text{pph}\) stands for the harmonic mean defined by

\[
(x, y) \in \mathbb{R}^2 \mapsto \text{pph}(x, y) := \frac{xy}{x+y} (\text{sgn}(xy) + 1),
\]

with \(\text{sgn}(x) = 1\) if \(x \geq 0\) and \(\text{sgn}(x) = -1\) if \(x < 0\).

The motivation for the substitution of the arithmetic mean by the harmonic mean is the elimination of oscillations near strongly varying data thanks to the fact that

\[
|\text{pph}(x, y)| \leq 2 \min(|x|, |y|),
\]

replaces

\[
\left| \frac{x+y}{2} \right| \leq \max(|x|, |y|).
\]

Before making a detailed analysis of the properties of the new scheme \(S_{PPHA}\) we summarize the most important properties of the harmonic mean in the following proposition (properties 1 to 9 are proved in [5] and property 10 is straightforward).
Proposition 1 Properties of the harmonic mean:
For all \((x, y) \in \mathbb{R}^2\), the harmonic mean \(\text{PPH}(x, y)\) satisfies
1. \(\text{PPH}(x, y) = \text{PPH}(y, x)\).
2. \(\text{PPH}(x, y) = 0\) if \(xy \leq 0\).
3. \(\text{PPH}(-x, -y) = -\text{PPH}(x, y)\).
4. \(\text{PPH}(x, y) = \frac{\text{sign}(x) + \text{sign}(y)}{2} \min(|x|, |y|) \left[ 1 + \frac{|x-y|}{x+y} \right] \).
5. \(|\text{PPH}(x, y)| \leq \max(|x|, |y|)\).
6. \(|\text{PPH}(x, y)| \leq 2 \min(|x|, |y|)\).
7. For \(x, y > 0\), \(\min(x, y) \leq \text{PPH}(x, y) \leq \frac{x+y}{2}\).
8. If \(x = O(1)\), \(y = O(1)\), \(|y-x| = O(h)\) and \(xy > 0\) then \(|\frac{x+y}{2} - \text{PPH}(x, y)| = O(h^2)\).
9. \(|\text{PPH}(x_1, y_1) - \text{PPH}(x_2, y_2)| \leq 2 \max(|x_1 - x_2|, |y_1 - y_2|)\).
10. For all \((c_1, c_2) \in \mathbb{R}^2\),
    \[
    |c_1 x - c_2 \text{PPH}(x, y)| \leq \max(|c_1|, |c_2|) \max(|x|, |y|) \text{ if } c_1 c_2 \geq 0, \\
    |c_1 x - c_2 \text{PPH}(x, y)| \leq (|c_1| + |c_2|) \max(|x|, |y|) \text{ if } c_1 c_2 < 0.
    \]

3 Convergence and Regularity
We recall the following definitions.

Definition 1 Convergence of a subdivision scheme:
A dyadic subdivision scheme \(S\) is said to be uniformly convergent if
\[
\forall f \in l^\infty(\mathbb{Z}), \exists S^\infty f \in C^0(\mathbb{R}) \text{ s.t. } \lim_{j \to +\infty} \sup_{n \in \mathbb{Z}} |(S^j f)_n - S^\infty f(n2^{-j})| = 0.
\]

Definition 2 \(C^\alpha\)-convergence of a subdivision scheme:
A convergent subdivision scheme \(S\) is said to be \(C^\alpha\)-convergent if for all \(f \in l^\infty(\mathbb{Z}), S^\infty f \in C^\alpha\) where
for $0 < \alpha \leq 1$,

$$C^{\alpha^-} = \{ f \ \text{continuous, bounded and verifying} \ \forall \alpha_1 < \alpha, \ \exists C > 0, \ s.\ t. \ \forall x, y \in \mathbb{R},$$

$$|f(x) - f(y)| \leq C|x - y|^\alpha_1 \},$$

and for $\alpha > 1$, writing $\alpha = p + r > 0$ with $p \in \mathbb{N}$ and $0 \leq r < 1$,

$$C^{\alpha^-} = \{ f \ \text{with} \ f^{(p)} \in C^r \}.$$  

**Definition 3** $L^\infty$ stability of the limit function:

Let $S$ be a linear uniformly convergent subdivision scheme and let $\phi$ be its limit function defined by $\phi = S^\infty \delta$ with $\delta_0 = 0 \ \forall n \in \mathbb{N}\ \backslash\ \{0\}$ and $\delta_0 = 1$. The limit function $\phi$ is said to be $L^\infty$ stable if:

$$\exists A, B > 0 \ s.t. \ \forall f \in l^\infty(\mathbb{Z}), A||f||_\infty \leq || \sum_{n \in \mathbb{Z}} f_n \phi(.- n)||_{L^\infty} \leq B||f||_\infty,$$

where $||f||_\infty = \sup_{n \in \mathbb{Z}} \{|f_n|\}$.

In order to derive the convergence, we rewrite the nonlinear subdivision scheme $S_{\text{PPHA}}$ as a perturbation of a classical two-point linear subdivision scheme, $S_C$, introduced by G. Chaikin in [7] and defined by

$$ (S_C f)_{2n} = \frac{3}{4}f_n + \frac{1}{4}f_{n+1}, \quad (4) $$

$$ (S_C f)_{2n+1} = \frac{1}{4}f_n + \frac{3}{4}f_{n+1}. $$

The scheme $S_C$ is known to be convergent with a regularity $C^{2-}$ (i.e. for any $f \in l^\infty(\mathbb{Z}), S_C^\infty f \in C^{2-}$). Moreover, its limit function is $L^\infty$ stable.

Writing

**If** $|d^2 f_n| \geq |d^2 f_{n+1}|$,

$$ (S_{\text{PPHA}} f)_{2n} = \frac{3}{4}f_n + \frac{1}{4}f_{n+1} + \frac{1}{64}d^2 f_{n+1} - \frac{7}{64} \text{PPH}(d^2 f_n, d^2 f_{n+1}) $$

$$ (S_{\text{PPHA}} f)_{2n+1} = \frac{1}{4}f_n + \frac{3}{4}f_{n+1} - \frac{1}{64}d^2 f_{n+1} + \frac{5}{64} \text{PPH}(d^2 f_n, d^2 f_{n+1}) $$

**and if** $|d^2 f_n| < |d^2 f_{n+1}|$,

$$ (S_{\text{PPHA}} f)_{2n} = \frac{3}{4}f_n + \frac{1}{4}f_{n+1} - \frac{1}{64}d^2 f_n - \frac{5}{64} \text{PPH}(d^2 f_n, d^2 f_{n+1}) $$

$$ (S_{\text{PPHA}} f)_{2n+1} = \frac{1}{4}f_n + \frac{3}{4}f_{n+1} + \frac{1}{64}d^2 f_n - \frac{7}{64} \text{PPH}(d^2 f_n, d^2 f_{n+1}) $$

6
we get that \( S_{\text{PPHA}} \) can be expressed as

\[
S_{\text{PPHA}} f = S_{c} f + F(d^2 f).
\]  

(5)

Introducing the function

\[
R(x, y) = \begin{cases} 
  y - \text{PPH}(x, y) & \text{if } |x| \geq |y|, \\
  -x + \text{PPH}(x, y) & \text{if } |x| < |y|,
\end{cases}
\]

(6)

the expression of \( F \) reads

\[
F(d^2 f)_{2n} = \frac{1}{64} R(d^2 f_n, d^2 f_{n+1}) - \frac{6}{64} \text{PPH}(d^2 f_n, d^2 f_{n+1}),
\]

(7)

\[
F(d^2 f)_{2n+1} = -\frac{1}{64} R(d^2 f_n, d^2 f_{n+1}) - \frac{6}{64} \text{PPH}(d^2 f_n, d^2 f_{n+1}).
\]

(8)

Before analyzing the convergence and the stability of \( S_{\text{PPHA}} \), we establish the following useful properties of the function \( R \): 

**Proposition 2** Properties of the function \( R \):

1. For all \((x, y) \in \mathbb{R}^2\), \(|R(x, y)| \leq \max(|x|, |y|)\).
2. For all \((x_1, y_1), (x_2, y_2) \in \mathbb{R}^2\),

\[
|R(x_1, y_1) - R(x_2, y_2)| \leq \max(|x_1 - x_2|, |y_1 - y_2|).
\]

**Proof**

Property 1 is a direct consequence of Proposition 1-10. To get Property 2 we note that the function \( R \) is continuous and we prove that its first-order partial derivatives \( R_x \) and \( R_y \) exist and satisfy \(||R_x|| + ||R_y|| \leq 1\) almost everywhere.

Indeed, if \( x \cdot y > 0 \)

\[
R_x(x, y) = \begin{cases} 
  -\frac{2y^2}{(x+y)^2} & \text{if } |x| > |y|, \\
  \frac{2x^2 + 2xy - 2y^2}{(x+y)^2} & \text{if } |x| < |y|
\end{cases}
\]

(9)

\[
R_y(x, y) = \begin{cases} 
  \frac{y^2 + 2xy - x^2}{(x+y)^2} & \text{if } |x| > |y|, \\
  -\frac{2y^2}{(x+y)^2} & \text{if } |x| < |y|
\end{cases}
\]

(10)

and if \( x \cdot y \leq 0 \)

\[
R_x(x, y) = \begin{cases} 
  0 & \text{if } |x| > |y|, \\
  -1 & \text{if } |x| < |y|
\end{cases}
\]

(11)
\[ R_y(x, y) = \begin{cases} 
1 & \text{if } |x| > |y|, \\
0 & \text{if } |x| < |y|. 
\end{cases} \tag{12} \]

Therefore, by direct calculation, \( ||R_x|| + ||R_y|| \) is bounded almost everywhere by one that concludes the proof. \[ \square \]

To analyze the convergence of \( S_{PPHA} \), we use the following result proved in [3], [2]:

Let \( S_{NL} \) be a subdivision scheme defined by

\[ \forall f \in l^\infty(\mathbb{Z}), \ \forall n \in \mathbb{Z} \quad (S_{NL}f)_n = (Sf)_n + F(\delta f)_n, \tag{13} \]

where \( F \) is a nonlinear operator defined on \( l^\infty(\mathbb{Z}) \), \( \delta \) is a linear and continuous operator on \( l^\infty(\mathbb{Z}) \) and \( S \) is a linear and convergent subdivision scheme with an \( L^\infty \) stable limit function. Then,

**Theorem 1** If \( F, S \) and \( \delta \) given in (13) verify:

\[ \exists M > 0 \ s.t. \ \forall f \in l^\infty(\mathbb{Z}) \quad ||F(f)||_\infty \leq M||f||_\infty, \tag{14} \]

\[ \exists c < 1 \ s.t. \ \forall f \in l^\infty(\mathbb{Z}) \quad ||\delta S(f) + \delta F(\delta f)||_\infty \leq c||\delta f||_\infty, \tag{15} \]

then the subdivision scheme \( S_{NL} \) is uniformly convergent. Moreover, if \( S \) is \( C^\alpha \) convergent then, \( S_{NL} \) is \( C^\beta \) convergent with \( \beta = \min(\alpha, -\log_2(c)) \).

Using Theorem 1, we will prove the following result:

**Theorem 2** The nonlinear subdivision scheme \( S_{PPHA} \) is \( C^\beta \) convergent with \( \beta \geq -\log_2(\frac{13}{64}) > 1. \)

**Proof**

For the perturbation \( F \) defined by (7) and (8), it is easy to see using Proposition 1-5 and Proposition 2-1 that for all \( f \in l^\infty(\mathbb{Z}) \),

\[ ||F(f)||_\infty \leq \frac{7}{64}||f||_\infty, \tag{16} \]

i.e. hypothesis (14).

We now consider hypothesis (15) related, in this case, to the contraction of the second-order differences \( (d^2 f) \). To simplify the notations, we call
\( f^1 = \text{SPPHA}(f) \), thus

\[
(d^2 f^1)_{2n} = \frac{1}{64} (16(d^2 f)_n - 6 \text{PPH}(d^2 f_{n-1}, d^2 f_n) + 6 \text{PPH}(d^2 f_n, d^2 f_{n+1}) \\
- R(d^2 f_{n-1}, d^2 f_n) - 3 R(d^2 f_n, d^2 f_{n+1})) \\
\]

\[
(d^2 f^1)_{2n+1} = \frac{1}{64} (16(d^2 f)_{n+1} + 6 \text{PPH}(d^2 f_n, d^2 f_{n+1}) - 6 \text{PPH}(d^2 f_{n+1}, d^2 f_{n+2}) \\
+ 3 R(d^2 f_n, d^2 f_{n+1}) + R(d^2 f_{n+1}, d^2 f_{n+2}))
\]

Using properties 5 and 10 of Proposition 1 as well as property 1 of Proposition 2 we deduce that for all \( f \in l^\infty(\mathbb{Z}) \)

\[ ||d^2 f^1||_{\infty} \leq \frac{13}{32} ||d^2 f||_{\infty}. \quad (17) \]

Therefore, hypothesis (15) of Theorem 1 is satisfied and consequently, the convergence of \( \text{SPPHA} \) is achieved.

For the regularity, we again use Theorem 1. According to the values \( \alpha = 2 \) and \( c = \frac{13}{32} \) we get the regularity constant \( \beta = \min (2, -\log_2 \left( \frac{13}{32} \right)) \approx 1.299 \). □

**Numerical Regularity**

Following [21], the regularity of a limit function can be evaluated numerically. Using \( S_1 \) and \( S_2 \) the subdivision schemes for the differences of order 1 and 2 associated to \( \text{SPPHA} \) (which can be derived due to the specific definition of \( \text{SPPHA} \)), the following quantities are estimated for \( k = 1, 2 \) and different values of \( j \):

\[
-\log_2 \left( 2^k \left( \frac{||(S_{k+1}^j f)_{n+1} - (S_k^j f)_n||_{\infty}}{||(S^j_k f)_{n+1} - (S^j_k f)_n||_{\infty}} \right) \right).
\]

They provide an estimate for \( \beta_1 \) and \( \beta_2 \) such that the limit functions belong to \( C^{1+\beta_1-} \) and \( C^{2+\beta_2-} \). From Table 1, the numerical estimate of the regularity is \( C^{2.438-} \). Recalling that the corresponding numerical estimate for the linear scheme [14] is \( C^{2.67-} \), we observe that the nonlinear perturbation has a very weak influence on the regularity.

**4 Stability**

We first recall the following definition.
Table 1: Numerical estimates of the limit functions regularity $C^{1+\beta_1-}$ and $C^{2+\beta_2-}$ for $S_{PPHA}$.

**Definition 4** Stability of a convergent scheme:

A convergent subdivision scheme is stable if

$$\exists C < +\infty \text{ s.t. } \forall f^0, g^0 \in L^\infty(\mathbb{Z}), \quad ||S^\infty f - S^\infty g||_{L^\infty} \leq C||f^0 - g^0||_\infty.$$

As for the convergence, to derive the stability of $S_{PPHA}$ we use the following Theorem of [2].

**Theorem 3** If $F, S$ and $\delta$ given in (13) verify: $\exists M > 0, c < 1$ such that $\forall f, g \in l^\infty(\mathbb{Z})$,

$$||F(f) - F(g)||_\infty \leq M||f - g||_\infty,$$  \hspace{1cm} (19)

$$||\delta(S_{NL}f - S_{NL}g)||_\infty \leq c||\delta(f - g)||_\infty,$$  \hspace{1cm} (20)

then the nonlinear subdivision scheme $S_{NL}$ is stable.

Using Theorem 3, we will prove the following result:

**Theorem 4** The scheme $S_{PPHA}$ is stable.

**Proof**

We check the hypotheses of Theorem 3.

First, we start with hypothesis (19) for $F$.
Using the expressions of $F$, (7) and (8), Proposition 1-9 and Proposition 2-2, we get for all $f, g \in l^\infty(\mathbb{Z})$

$$||F(f) - F(g)||_\infty \leq \frac{1 + 7 \cdot 2}{64}||f - g||_\infty.$$  \hspace{1cm} (Case 1) or $k = 2n$ (Case 2). Only Case 1 is considered since the bound expressions are similar in both cases. Using Proposition 1-9 as well as Proposition 2-2 we get
\[64|(d^2 f^1)_{2n+1} - (d^2 g^1)_{2n+1}| \leq 16|((d^2 f)_{n+1} - (d^2 g)_{n+1})|
+6|\text{PPH}(d^2 f_n, d^2 f_{n+1}) - \text{PPH}(d^2 g_n, d^2 g_{n+1})|
+6|\text{PPH}(d^2 f_{n+1}, d^2 f_{n+2}) - \text{PPH}(d^2 g_{n+1}, d^2 g_{n+2})|
+3|R(d^2 f_n, d^2 f_{n+1}) - R(d^2 g_n, d^2 g_{n+1})|
+|R(d^2 f_{n+1}, d^2 f_{n+2} - R(d^2 g_{n+1}, d^2 g_{n+2})|
\leq (16 + 12 + 12 + 3 + 1)||((d^2 f) - (d^2 g))||_{\infty}
= 44||((d^2 f) - (d^2 g))||_{\infty}.

Thus, the hypotheses of Theorem (20) are verified and the stability of \(S_{\text{PPHA}}\) is established.

\[\Box\]

5 Order of approximation

In this section, we consider the reproduction of polynomials and the order of approximation of \(S_{\text{PPHA}}\).

We recall the following definitions.

**Definition 5** Reproduction of polynomials:

A dyadic subdivision scheme \(S\) is said to reproduce polynomials of degree \(k\) if for all polynomial \(P\) of degree \(k\) and for all sequence \(f\) such that \(\forall n \in \mathbb{Z}, f_n = P(n)\) then:

\[\exists \tilde{P}\] a polynomial of degree \(k\) such that \((Sf)_n = \tilde{P}(2^{-1}n)\).

**Definition 6** Order of approximation:

A dyadic subdivision scheme \(S\) is said to have an order \(k\) of approximation if for all function \(g \in C^k\) and all \(h > 0\), \(f = g(h)\) implies that

\[|Sf - g(2^{-1}h)| \leq C h^k.\]

We then have the following result:

**Proposition 3** Reproduction of polynomials:

\(S_{\text{PPHA}}\) reproduces the polynomials of degree 2 with the translation of \(\frac{1}{4}\).
We remark that for any $P$, polynomial of degree 2, and $p = (P(n))_{n \in \mathbb{Z}}$, we have
\[ \text{PPH}(d^2 p_n, d^2 p_{n+1}) = \frac{d^2 p_n + d^2 p_{n+1}}{2}. \]
Therefore, for any initial sequence $p = (p_n)_{n \in \mathbb{Z}}$, $S_{\text{PPHA}}(p)$ coincides with the application to $p$ of the linear scheme [14]. In particular, the results of N. Dyn, M.S. Floater and K. Hormann [14] can be applied and the property of definition 5 is satisfied with $\tilde{P}(.) = P(\cdot + 1/4)$.

Concerning the order of approximation the following result holds.

**Proposition 4** Order of approximation:
For any function $g \in C^4([0, 1])$ and $h > 0$, if $f = (g((n - 1/2)h))_{n \in \mathbb{Z}}$, then if $d^2 f_n d^2 f_{n+1} > 0$ for all $n \in \mathbb{Z}$, then
\[ ||S_{\text{PPHA}} f_n - g(2^{-1}hn)||_\infty = O(h^4), \]
otherwise
\[ ||S_{\text{PPHA}} f_n - g(2^{-1}hn)||_\infty = O(h^3). \]

**Proof**
According to Proposition 1, if for all $n \in \mathbb{N}$, $d^2 f_n d^2 f_{n+1} > 0$ then
\[ |\text{PPH}(d^2 f_n, d^2 f_{n+1}) - \frac{d^2 f_n + d^2 f_{n+1}}{2}| = O(h^4). \]
Therefore, if $S$ stands for the linear scheme defined in [14], according to the definition of $S_{\text{PPHA}}$,
\[ ||S_{\text{PPHA}} f - S f||_\infty = O(h^4). \]
Since (see [14]) the scheme $S$ is of order of approximation 4 we get the result when $d^2 f_n d^2 f_{n+1} > 0$. Otherwise, the reproduction of polynomials leads to
\[ ||S_{\text{PPHA}} f_n - g(2^{-1}h(n))||_\infty = O(h^3). \]

**Remark 1** Following [21] one can also establish, using the stability of $S_{\text{PPHA}}$ that $||S_{\text{PPHA}}^\infty f - g||_\infty = O(h^3)$. 

12
6 Elimination of the Gibbs phenomenon

In this section, we focus on the behavior of the scheme in the presence of strongly varying data. The reference framework deals with the sampling of a step function as shown on Figure 1. As can be seen on the left in Figure 1, high-order linear schemes suffer from an oscillating behavior called Gibbs phenomenon.

According to D. Gottlieb and C.W. Shu [18], given a punctually discontinuous function $f$ and its sampling $f^h$ defined by $f^h_n = f(nh)$, the Gibbs phenomenon deals with the convergence of $S_\infty(f^h)$ towards $f$ when $h$ goes to 0. It can be characterized by two features ([18]):

1. Away from the discontinuity the convergence is rather slow and for any point $x$,
   \[ |f(x) - S_\infty(f^h)(x)| = O(h). \]

2. There is an overshoot, close to the discontinuity, that does not diminish with the reduction of $h$. Thus,
   \[ \max |f(x) - S_\infty(f^h)(x)| \text{ does not tend to zero with } h. \]

![Figure 1](image.png)

Figure 1: Comparison of limit functions for the same initial sequence (sampling of function (23)). Left, the linear scheme (1), right, the nonlinear scheme $S_{PPHA}$

We will now prove that the nonlinear scheme $S_{PPHA}$ does not suffer from the Gibbs phenomenon oscillations, as can be guessed from Figure 1.

We indeed have the following:
**Proposition 5** Elimination of Gibbs oscillations:
Given $0 \leq \xi \leq h$, let $f$ be any function defined by:

\[
\forall x \leq \xi, f(x) = f_-(x) \text{ with } f_- \in C^4([-\infty, \xi]), \\
\forall x \geq \xi, f(x) = f_+(x) \text{ with } f_+ \in C^4([\xi, +\infty]),
\]

with $f_-(\xi) > f_+(\xi)$.

If $h$ is sufficiently small to ensure that $d^2 f_0 < 0$ and $d^2 f_1 > 0$ we have:

- if $|x| \geq 3h$, $|f(x + \frac{1}{2}h) - S_{\text{PPHA}}^\infty(f^h)(x)| = O(h^3)$,
- if $|x| \leq 3h$, there exists $\alpha_h = 0(h)$ such that $f_-(0) + \alpha_h \geq S_{\text{PPHA}}^\infty(f^h)(x) \geq f_+(h) - \alpha_h$.

**Proof**

For any iteration $j$, there exists $p_j^-, p_j^+$ such that, for all $n \not\in [2p_j^-, 2p_j^+]$ the evaluation of $S_{\text{PPHA}}^{j+1}(f)_n$ is performed starting only from regular data. For $j = 0, p_0^- = -1, p_0^+ = 2$ and by induction, $p_j^- = -2^{j+1} - 2^j + 2, p_j^+ = 2^{j+1} + 2^j - 1$. Therefore, according to Proposition 4, for $x \geq 3h$, $|f(x + \frac{1}{2}h) - S_{\text{PPHA}}^\infty(f^h)(x)| = O(h^3)$.

To prove the second part of the proposition, we first consider the initial data and iterate the scheme.

We recall that, by hypothesis, for all $i \geq 0, f_+ = f_+ + O(h)$ and $f_0 = f_+ + O(h)$. Computing the second differences gives that $d^2 f_0 = O(h^2), d^2 f_2 = O(h^2)$ while $d^2 f_0 = f_1 - f_0 + O(h)$ and $d^2 f_1 = -(f_1 - f_0) + O(h)$. Applying the scheme $S_{\text{PPHA}}$ provides:

\[
(S_{\text{PPHA}}f)_{-2} = \frac{3}{4} f_{-1} + \frac{1}{4} f_0 + O(h^2), \\
(S_{\text{PPHA}}f)_{-1} = \frac{1}{4} f_{-1} + \frac{3}{4} f_0 + O(h^2), \\
(S_{\text{PPHA}}f)_0 = \frac{3}{4} f_0 + \frac{1}{4} f_1 + \frac{1}{64} (f_0 - f_1) + O(h), \\
(S_{\text{PPHA}}f)_1 = \frac{3}{4} f_0 + \frac{1}{4} f_{n+1} - \frac{1}{64} (f_0 - f_1) + O(h).
\]

One should notice that all these points belong to an interval of the form $[f^+ - O(h), f^- + O(h)]$. Without loss of generality, we focus on negative indices. A direct evaluation of second order differences gives:
\[ d^2 S_{\text{PPHA}} f_0 = (S_{\text{PPHA}} f)_1 - 2(S_{\text{PPHA}} f)_0 + (S_{\text{PPHA}} f)_{-1} = \frac{13}{64} (f_1 - f_0) + O(h), \]
\[ d^2 S_{\text{PPHA}} f_{-1} = (S_{\text{PPHA}} f)_0 - 2(S_{\text{PPHA}} f)_{-1} + (S_{\text{PPHA}} f)_{-2} = \frac{17}{64} (f_1 - f_0) + O(h), \]

and an other application of the scheme provides:

\[ (S^2_{\text{PPHA}} f)_n = (S^2_{SC} f)_n + O(h^2), n \in [2p_1^- - 3], \]
\[ (S^2_{\text{PPHA}} f)_{-2} = \frac{3}{4} \left( \frac{3}{4} f_{-1} + \frac{1}{4} f_1 \right) + \frac{3}{4} f_0 + \frac{c_1}{64} (f_0 - f_1) + O(h), \]
\[ (S^2_{\text{PPHA}} f)_{-1} = \frac{3}{4} \left( \frac{1}{4} f_{-1} + \frac{3}{4} f_1 \right) + \frac{3}{4} f_0 + \frac{c_2}{64} (f_0 - f_1) + O(h), \]
\[ (S^2_{\text{PPHA}} f)_0 = \frac{3}{4} f_0 + \frac{1}{4} f_1 + \frac{1}{2} \frac{17}{64} (f_0 - f_1) + O(h), \]

with \( c_1 = \frac{1}{4} - \frac{13}{64} - 5 \text{PPH} \left( \frac{13}{64}, \frac{17}{64} \right) \) and \( c_2 = \frac{3}{4} + \frac{13}{64} - 7 \text{PPH} \left( \frac{13}{64}, \frac{17}{64} \right) \) \((c_i < 0)\).

From this stage, we are now able to prove that Gibbs oscillations can not appear.

Since after two iterations the second order differences are bounded by \( \frac{17}{64} (f_1 - f_0) + O(h) \), thanks to (17),

\[ \forall j \geq 2, \forall n \in [p_{j-1}^- - 3], d^2 S_{\text{PPHA}} f_n \leq (\frac{13}{32})^j \frac{17}{64} (f_0 - f_1) + O(h). \]

According to (16) and due to the stability of \( S_C \) we get that the total perturbation is bounded for all \( j \geq 2 \) by

\[ \frac{7}{64} \sum_{m=1}^{\infty} \left( \frac{13}{32} \right)^m \frac{17}{64} (f_0 - f_1) = \frac{7}{64} \frac{13}{19} \frac{17}{64} (f_0 - f_1). \]

(21)

**Lower bound:**

Due to the “corner cutting property” of the scheme \( S_C \), for all \( j \geq 2 \), and all \( n \in [2p_{j-1}^- - 0] \), we get that

\[ S_{C}^{-2} (S^2_{\text{PPHA}} f)_n \in [f_0 + 0(h), \min\{ (S^2_{\text{PPHA}} f)_n, n \in [2p_1^- - 0] \} \}]. \]

Adding the total perturbation (21) we obtain finally that for all \( j \) and all \( n \in [2p_{j-1}^- - 0], (S_{\text{PPHA}} f)_n \geq f_+ - O(h) \).
Upper bound:

Taking into account the regularity of $f$ on $]-\infty, \xi[$ and the data after two iterations, a direct calculation gives that for $n \in [p_{j-1}, 2^j - 1]$,

$$(S_{ppha}^j f)_n = (S_C^j f)_n + O(h^2),$$

while for $n \in [2^j, 0]$,

$$(S_{ppha}^j f)_n \leq A_j f_{-1} + B_j f_1 + \frac{3}{4} f_0 + \frac{7}{64} \frac{13}{19} \frac{17}{64} (f_0 - f_1) + O(h). \quad (22)$$

Here, $A_{j+1}$ and $B_{j+1}, j \geq 2$ are provided from a convex combination of $A_j$ and $B_j$, therefore, according to their values for $j = 2$, $A_j, B_j \in \left[\frac{1}{16}, \frac{1}{4}\right]$ and $A_j + B_j = \frac{1}{4}$.

Rewriting the right hand side term of (22) we get that

$$(S_{ppha}^j f)_n \leq A_j (f_1 - f_0) + B_j (f_1 - f_0) + f_0 + \frac{7}{64} \frac{13}{19} (f_0 - f_1) + O(h) \leq f_0.$$

Therefore for all $n \in [p_{j-1}, 0], (S_{ppha}^j f)_n \leq f_\text{-} + O(h)$, that concludes the proof.

□

Before finishing this paper, we return to Figure 1 and to the comparison between the limit functions obtained with $S_{ppha}$ and the limit function obtained with linear subdivision schemes starting from the sampling $f^h$ of the discontinuous function:

$$f(x) = \begin{cases} sin(\pi x) & \text{for } x \in [0, 0.5[ \\ -sin(\pi x) & \text{for } x \in [0.5, 1]. \end{cases} \quad (23)$$

It appears from Figure 1 that the limit function of the nonlinear scheme $S_{ppha}$ (right) behaves much better close to the discontinuity than do the limit functions associated to the linear scheme of comparable complexity (left). Moreover, from Proposition 4 we know that the limit function of the scheme $S_{ppha}$ is, in regular regions, of higher order than the Chaikin scheme corresponding function.

## 7 Conclusions

In this paper, a new nonlinear subdivision scheme has been defined. It has many desirable properties. It is convergent with a regularity proved to be
at least $C^{1.209}$ and numerically estimated at $C^{2.438}$. By construction, it is adapted to the presence of isolated discontinuities, and the Gibbs phenomenon is eliminated. The scheme is also stable, a property that, due to nonlinearity, is not a consequence of the convergence. Moreover, its order of convergence is 3. Given that it is constructed from a four-point centered stencil, all these properties make this scheme an excellent candidate for various applications. An example is given in Figure 2 devoted to 2D curve generation.
