Abbreviated title for running headlines: Calix[6]tris-carboxylic acid receptors for ammonium ions

Abstract

The ability of calix[6]arene tris-carboxylic acid derivatives to include ammonium guests has been investigated both in solution and in the solid state. NMR studies and crystallographic data showed that the highly flexible calix[6]arene structures can be shaped in a well defined cone conformation thanks to the formation of an ion-paired cap between the carboxylate
groups of the calixarene and their ammonium counter-ions. The resulting supramolecular edifices exhibit remarkable host-guest properties toward ammonium ions even in polar and protic solvents. The recognition process has been rationalized in the solid state by the combination of hydrogen bonding, electrostatic and CH–π interactions, and a remarkable C3-complementarity between the well-organized binding carboxylates of the host and the ammonium guest. Very interestingly, the endo-cavity complexation of large polycyclic ammonium ions as well as bioactive ammonium ions has been clearly demonstrated through NMR spectroscopy. Finally, the tuning of the nature of the ammonium ions involved in the supramolecular cap led to highly responsive molecular receptors.

Introduction

The recognition of ammonium ions by synthetic receptors is a topic of great interest since it can lead to a better understanding of biological recognition processes and to the development of efficient sensors toward bioactive molecules. Calix[6]arenes are attractive cavity-shaped platforms for the design of such hosts. Indeed, the introduction of a binding site devoted to ammonium ions can be readily achieved through the alkylation of their phenolic units with appropriate functional groups and, in contrast to the smaller calix[4]arenes, the size of their cavity is suitable for the deep inclusion of relatively large organic molecules. However, the host-guest properties of calix[6]arenes toward ammonium ions were scarcely studied. This is mainly due to their high conformational flexibility which usually needs to be restricted in order to obtain receptors with a well-defined cavity. Thus, only a few examples of calix[6]arenes bearing ester groups as well as crown ether or aza-cryptand units have been described. With such receptors, the host-guest recognition may involve π-cationic, CH–π, π–π interactions and hydrogen-bonding. The use of electrostatic interactions for the binding of ammonium ions by calix[6]arene hosts was also reported. Notably, the extraction ability
of organo-soluble tOctyl-calix[6]arene hexa-acetic acid derivatives toward biological amino compounds such as nucleobases, amino acids or catecholamines was recently studied\textsuperscript{12} but the nature of the host-guest adducts remained unclear and the endo-cavity complexation of the ammonium ions was not evidenced.

We have shown that the conformational behaviour of calix[6]arenes can be controlled by the grafting of three ammonium arms on their narrow rim.\textsuperscript{13} The resulting calix[6]tris-ammoniums are constrained in cone conformation through an ion-paired cap formed by the assembly of their cationic arms and the counter-anions. In organic media, these simple polarized hosts behave as remarkable endo-receptors since, besides its structural role, the supramolecular cap provides an efficient binding site for polar neutral guests through charge-dipole interactions and hydrogen bonding (Figure 1, left). In order to design calix[6]arene based receptors able to include ammonium ions in their cavity, we were interested in studying the opposite way for the rigidification of the calixarene core, \textit{i.e.} an ion-paired cap consisting in three carboxylate arms and their counter-cations. With such poly-carboxylate receptors, strong electrostatic interactions were notably expected for the stabilization of the host-guest adducts.\textsuperscript{14} Our first aim was to contribute to the understanding of the factors which govern the recognition of ammonium ions by poly-anionic hosts possessing a hydrophobic cavity. On the other hand, we wanted to study the feasibility of developing simple and efficient sensors for biologically important ammonium ions.

In the present work, we describe the remarkable host-guest properties of calix[6]tris-acid derivatives 1\textsuperscript{15} and 2\textsuperscript{16} (Figure 1, right) toward ammonium ions. In contrast to 1, the open cavity of calix[6]tris-acid 2 was expected to allow the inclusion of large ammonium guests.

Results

$^1$H NMR study of the host-guest properties of calix[6]tris-acid 1 toward ammonium ions.

First, the ability of calix[6](COOH)$_3$ 1 (Figure 2a) to host small ammonium ions R’NH$_3^+$ (with R’ = Et and Pr) was investigated by $^1$H NMR spectroscopy at 294 K. Thus, the addition of 1 equiv. of R’NH$_2$ into a CDCl$_3$ solution of 1 led to a broadening of its NMR signals and the formation of a new species displaying signals below 0 ppm (Figure 2b with R’ = Pr). These high-field resonances suggest the endo-cavity complexation of a R’NH$_3^+$ molecule formed by deprotonation of the COOH groups of the host 1. With 2 equiv. of R’NH$_2$, all the NMR signals sharpened and the new species remained the only one observable in solution. It displayed a $C_{3v}$-symmetrical profile characteristic of the endo-complexes 1$^{2H+}$,R’NH$_3^+$⊃⊃ ⊃⊃ ⊃⊃ R’NH$_3^+$ (Figure 2c with R’ = Pr, Scheme 1). Indeed, beside the resonances of the host and one equivalent of exo-R’NH$_3^+$, high-field signals show the strong binding of exactly one equiv. of the R’NH$_3^+$ guest in the heart of the calixarene cavity ($\delta_{\text{CH}_3} = -1.38$ and $-1.75$ ppm for R’
= Et and Pr respectively). In contrast to calix[6](COOH)$_3$ 1, the endo-complexes 1$^{2H+,R’NH_3^+}$-$\supset$R$’NH_3^+$ possess two sharp doublets for the ArCH$_2$ methylene protons, showing a cone-cone inversion of their calixarene skeleton that is slower than the NMR time scale. Moreover, both their ArH and tBu signals are largely differentiated (0.68 < $\Delta \delta_{\text{ArH}}$ < 0.78 and 0.59 < $\Delta \delta_{\text{tBu}}$ < 0.64 ppm) while those of 1 are characteristic of a straight cone conformation ($\Delta \delta_{\text{ArH}} = 0.05$ and $\Delta \delta_{\text{tBu}} = 0.04$ ppm, see the structure displayed in Figure 1). All these NMR data clearly indicate that, upon complexation of the ammonium guest, the calixarene structure of 1$^{2H+}$ adopts a more rigid and flattened cone conformation with the methoxy groups expelled toward the outside of the cavity ($\delta_{\text{OMe}} = 3.82$ and 3.85 ppm for R’ = Et and Pr respectively) (See the insert displayed in Scheme 1). The addition of a third equiv. of R’NH$_2$ led to a high-field shift of the CH$_2$COO signal of the calixarene host (from 4.42 for 1$^{2H+}$ to 4.34 ppm for 1$^{3H+}$ in the case of R’ = Pr for instance) indicating the total deprotonation of the carboxylic groups and thus the formation of the endo-complexes 1$^{3H+\cdot2R’NH_3^+\cdotR’NH_3^+}$ (Figure 2d with R’ = Pr, Scheme 1). Indeed, the CH$_2$COO resonance did not change upon the subsequent addition of a large excess of R’NH$_2$. Surprisingly, the addition of picrate salts of either ethylammonium or propylammonium (i.e. EtNH$_3^+,\text{Pic}^-$ or PrNH$_3^+,\text{Pic}^-$) to a CDCl$_3$ solution of 1 also led to their inclusion and two equiv. of ammonium ions were needed for the formation of the endo-complexes 1$^{R’NH_3^+\cdot2R’NH_3^+\cdot2\text{Pic}^-}$ (with R’ = Et or Pr) as the only observable species (Scheme 1). It is noteworthy that the ethyl ester and primary amide derivatives of 1 [i.e. calix[6](COOEt)$_3$ and calix[6](CONH$_2$)$_3$] were unable to include these ammonium ions under similar conditions. Finally, the endo-complex 1$^{H+,R’NH_3^+\cdotR’NH_3^+\cdot\text{Pic}^-}$ (with R’ = Pr) was also obtained by the addition of 1 equiv. of R’NH$_3^+,\text{Pic}^-$ and 1 equiv. of its corresponding free amine to a CDCl$_3$ solution of 1 (Scheme 1).

These NMR studies emphasize the remarkable ability of calix[6]tris-acid 1 for the endo-complexation of small ammonium ions. Similarly to the calix[6]tris-ammonium receptors
(Figure 1, left), the crucial rigidification of the calixarene structure clearly takes place thanks to the assembly of a supramolecular cap that closes the narrow rim. Indeed, the exo-binding of at least one ammonium ion (i.e. exo-R'NH₃⁺) is required for the formation of the endo-complexes. Very interestingly, either the carboxylic or the carboxylate groups can efficiently elaborate this cap since it has been evidenced that the calix[6]tris-acid 1 can host small ammonium ions whatever its protonation state (Scheme 1). This highlights the versatility of the calix[6]tris-acid 1 in the recognition of ammonium ions.

**Figure 2.** ¹H NMR spectra (300 MHz, CDCl₃) at 294 K: (a) calix[6]tris-acid 1; (b) Mixture of 1 and 1²⁺PrNH₃⁺⊃⊃PrNH₃⁺ obtained upon the addition of 1 equiv. PrNH₂ to 1; (c) 1⁻²⁺PrNH₃⁺⊃⊃PrNH₃⁺ obtained upon the addition of 2 equiv. PrNH₂ to 1; (d) 1⁻³⁺PrNH₃⁺⊃⊃PrNH₃⁺ obtained upon the addition of 3 equiv. PrNH₂ to 1. ●: exo-PrNH₃⁺. ▼: included PrNH₃⁺. Residual solvent has been labeled “S”.

Scheme 1. The four different ways for the endo-complexation of ammonium ions with calix[6]tris-acid 1 (in CDCl₃).

Characterization of the endo-complex 1⁻[^3H+,2EtNH₃+]⁻EtNH₃⁺⁻⁻ in the solid state.

Upon slow diffusion of ether, X-ray quality crystals of the endo-complex 1⁻[^3H+,2EtNH₃+]⁻EtNH₃⁺⁻⁻ were grown at 4 °C out of a CHCl₃ solution of the calix[6]tris-acid 1 and 3 equiv. of EtNH₂. The resulting molecular structure displayed in Figure 3 provides a rare example of a calixarene including an ammonium guest deeply in its cavity. The calixarene adopts a flattened cone conformation with the carboxylates arms directed toward the inside of the cavity, the tBu groups of the anisol moieties closing the entrance of the cavity at the large rim. The presence of three ethylammonium molecules as well as the short and quasi-equivalents C-O bond lengths of the CO₂ groups (dC-O = 1.188 to 1.266 Å) attest that the three carboxylic groups are deprotonated (Figure 3, top left). One ethylammonium molecule stands in the heart of the cavity and orients its dipolar moment along the C₃v axis of the calixarene denoting dipole-charge interactions with the tris-anionic binding site. Moreover,
the three carboxylate groups point specifically toward the NH$_3^+$ group of the guest at H bond distances (dO$_{10}$···N$_2$ = 2.817 Å, dO$_{2}$···N$_2$ = 2.781 Å and dO$_{6}$···N$_2$ = 2.776 Å). Thus, the C$_3$-binding geometry displayed by the carboxylates allows a remarkable preorganization for the recognition of the ammonium guest (Figure 3, top right). As previously observed on closely related host-guest adducts, the methyl group of the guest is oriented toward an aromatic ring of the calixarene at a perpendicular distance of ca. 3.61 Å, attesting a stabilizing CH-π interaction. All these features emphasize a strong complementarity in terms of size, shape and electronic structures between the calixarene host and its ammonium guest. The two other ethylammonium molecules (exo-EtNH$_3^+$) bridge the three carboxylate groups thanks to ion-paired interactions and to the establishment of four hydrogen bonds (dO$_{10}$···N$_6$ = 2.730 Å, dO$_{2}$···N$_6$ = 2.707 Å, dO$_{7}$···N$_4$ = 2.729 Å and dO$_{3}$···N$_4$ = 2.808 Å). Hence, as shown in solution through the NMR studies, the role of these exo-EtNH$_3^+$ molecules consists in assembling the carboxylate arms in a supramolecular cap which shapes the calixarene structure in the required cone conformation and furthermore provides a well preorganized binding site for ammonium ions. Very interestingly, intermolecular H bonds are observable in the lattice. They involve the exo-EtNH$_3^+$ molecules and the carboxylate groups of two calix[6]arenes which are assembled in a tail-to-tail fashion (dO$_{11}$···N$_4$ = 2.735 Å, dO$_{11}$···N$_6$ = 2.830 Å) (Figure 3, bottom). Thus, in the solid state, two calix[6]arene subunits share their exo-ammonium ions, providing four additional intermolecular H bonds which further stabilize the supramolecular edifice. This denotes a cooperative process since each of the six ammonium molecules involved in the dimeric self-assembly establishes its maximum of H bond interactions.
Figure 3. X-ray structure of $1^{3}\text{H}^+,2\text{EtNH}_3^+ \supset \supset \text{EtNH}_3^+$ displaying the H bonds (dark dashed lines) between the NH$_3^+$ and COO$^-$ groups and the CH-$\pi$ interaction (blue dashed line) between the methyl group of the guest and an aromatic ring of the host. Hydrogen atoms and solvents of crystallization were omitted for clarity. The calixarene host and the ammonium ions are depicted respectively in capped stick and ball and stick models. Top left: side view of the monomeric subunit. Top right: top view of the monomeric subunit; exo-ammonium ions were omitted for clarity. Bottom: side view of the dimeric assembly; the molecules have been colorized by symmetry equivalence.

NMR studies of the endo-complexation of various ammonium ions by calix[6]tris-acids 1 and 2.

Similarly to 1, the host-guest behavior of calix[6]tris-acid 2 toward PrNH$_3^+$ was investigated by $^1$H NMR spectroscopy in CDCl$_3$ at 294 K. In this case, 3 equiv. of PrNH$_2$ were needed for
the exclusive formation of an endo-complex. Moreover, no ammonium ion inclusion could be
detected after the introduction of an excess of PrNH₃⁺,Pic⁻ in a CDCl₃ solution of 2, even at
low temperature (260 K). These results show that, in contrast to 1, the calix[6]tris-acid 2 has
to be totally deprotonated (i.e. 2⁻³H⁺) for an efficient endo-complexation of ammonium ions.

Hence, in a second set of NMR experiments, we tested the ability of the hosts 1⁻³H⁺ and 2⁻³H⁺ for the recognition of ammonium ions of various size, shape and structure. In particular, we wanted to study if an inclusion of biologically important ammonium ions was possible inside the hydrophobic cavity of these receptors. The ammonium ions which were successfully endo-complexed are displayed in Scheme 2. In all cases, free and included guests were seen in slow exchange indicating their strong binding by the calixarene host. The observed NMR complexation induced upfield shifts (CIS)²³ attest to the deep inclusion of the guests in the cavity (for the CIS, see the values displayed in Scheme 2). Thus, host 1⁻³H⁺ was able to endo-complex a β-hydroxy ammonium ion [derived from (±)-1-amino-propan-2-ol]²⁴ as well as a secondary cyclic ammonium ion (i.e. pyrrolidinium). Upon similar conditions (CDCl₃, 294K), bulkier ammonium ions derived from trimethylamine, piperidine (PIPNH) and phenethylamine (PEANH₂) were not detected in the cavity of 1⁻³H⁺. In these cases, the calixarene structure displayed high-field shifted resonances for the methoxy groups showing that they partially occupied the hydrophobic cavity. However, the endo-complexation of PEANH₂ and PIPNH was successfully achieved with host 2⁻³H⁺, thus leading to the corresponding endo-complexes 2⁻³H⁺,²PEANH⁺ ⊃⊃ ⊃⊃ PEANH₃⁺ and 2⁻³H⁺,²PIPNH⁺ ⊃⊃ ⊃⊃ PIPNH₂⁺.²⁵ This result clearly demonstrates that the removal of the t-Bu groups of the anisol moieties is an efficient strategy for the opening of the calixarene cavity and the binding of large guests. Similarly, the corresponding ammonium ions of the bulky tryptamine, 6-methoxytryptamine and of an organosoluble dopamine derivative (i.e. 3,4-dimethoxyphenethylamine) were also endo-complexed by host 2⁻³H⁺. Finally, to our delight, the inclusion of biological polyamines
such as spermine and spermidine was also detected inside the cavity of $2^{-3\text{H}^+}$. In the case of the spermidine, two endo-complexes were observed in a $ca.$ 1:1 ratio showing two different ways of binding (Scheme 2).

Scheme 2. Endo-complexation of ammonium ions by receptors $1^{-3\text{H}^+}$, $2^{-3\text{H}^+}$ in CDCl$_3$ and NMR complexation induced upfield shifts (CIS) of various ammonium guests.

The stability of the endo-complexes $1^{-3\text{H}^+}, 2^{-3\text{H}^+}$ was evaluated by NMR spectroscopy. Their $^1\text{H}$ NMR spectra was not affected over a large temperature range (223-330 K). In particular, the $in$ and $out$ guest exchange was still slower than the NMR time scale at high temperature (330 K), confirming a strong association with the hosts. Surprisingly, these host-guest adducts reveal to be remarkably resistant in polar and protic solvents which usually compete for H-bonding. Indeed, the endo-complexes $1^{-3\text{H}^+}, 2^{-3\text{H}^+}$ also survived in pure CD$_3$OD and 50 % of the endo-complex was still present in a $ca.$ 4:1 DMSO-D$_6$/D$_2$O solution after addition of an excess of PrNH$_2$ ($ca.$ 30 equiv.). In contrast, the endo-complex $1^{\text{PrNH}_3^+, 2\text{Pic}^-}$, which
possesses a cap maintained only through H-bonding, was destroyed by the addition of a small amount of CD$_3$OD (≈ 1%) into the CDCl$_3$ solution. This last result emphasizes the superiority of the ionic interactions in the stabilization of these host-guest adducts.

**Tuning of the ion-paired cap.**

As shown above, the endo-complexation of an ammonium guest in the cavity of the calix[6]tris-acids 1 and 2 requires the exo-complexation of at least one bridging exo-ammonium ion for the assembly of the supramolecular cap. Thus, the next degree of sophistication consisted in the elaboration of receptors displaying a supramolecular cap constructed with an exo-ammonium ion which differs from the included one. Indeed, with such receptors, the design of highly responsive sensors for ammonium ions can be envisaged.

For this, our strategy was based on the formation of the cap thanks to a bulky ammonium ion (i.e. tBuNH$_3^+$) unable to be included in the cavity. Hence, the tris-tBuNH$_3^+$ salts of 1 and 2, namely 1$^{-3}$H+,3tBuNH$_3^+$ and 2$^{-3}$H+,3tBuNH$_3^+$ were isolated in 82 % and 98 % yields respectively (Scheme 3). Their $^1$H NMR spectra in CDCl$_3$ reflected C$_3v$-symmetrical species rigidified in a major cone conformation and no inclusion of tBuNH$_3^+$ was observed (Figure 4a, for 2$^{-3}$H+,3tBuNH$_3^+$).

For R = NO$_2$: 1 or 2

For R = tBu: 1$^{-3}$H+,3tBuNH$_3^+$ (R = tBu)

For R = NO$_2$: 1$^{-3}$H+,2tBuNH$_3^+$ (R = NO$_2$)
Scheme 3. Preparation and host-guest properties (in CDCl$_3$) of the receptors $1^{-3H+},3tBuNH_3^+$ and $2^{-3H+},3tBuNH_3^+$. i) $tBuNH_2 (> 3$ equiv.), CHCl$_3$, $82\%$ and $98\%$ respectively.

The host-guest behavior of both salts was investigated by $^1$H NMR spectroscopy. The addition of 1 equiv. of PrNH$_2$ into a CDCl$_3$ solution of either $1^{-3H+},2tBuNH_3^+$ or $2^{-3H+},2tBuNH_3^+$ led to the corresponding endo-complexes $1^{-3H+},2tBuNH_3^+ \varpi \text{PrNH}_3^+$ and $2^{-3H+},2tBuNH_3^+ \varpi \text{PrNH}_3^+$ as the only observable species. Thus, this very selective recognition process was associated to the release of one equivalent of $tBuNH_2$. The driving force for the counter-ion exchange and the inclusion of the ammonium ion should stand in part in the establishment of additional CH-$\pi$ interactions in the host-guest adduct. It is noteworthy that upon addition of less than one equivalent of the PrNH$_2$, no exo-PrNH$_3^+$ could be detected. Hence, the association constant of PrNH$_3^+$ toward $1^{-3H+},2tBuNH_3^+$ was estimated to be at least $1.2 \times 10^5$ M$^{-1}$. Similarly, only 1 equiv. of the bulky phenethylamine was necessary for the exclusive formation of the endo-complex $2^{-3H+},2tBuNH_3^+ \varpi \text{PEANH}_3^+$ (Figure 4b).

Figure 4. $^1$H NMR spectra (300 MHz, CDCl$_3$) at 294 K. (a) $2^{-3H+},3tBuNH_3^+$; (b) $2^{-3H+},2tBuNH_3^+ \varpi \text{PEANH}_3^+$ obtained upon the addition of 1 equiv. of PEANH$_2$ to $2^{-3H+},3tBuNH_3^+$. ▼: included PEANH$_3^+$. Residual solvent has been labeled “S”.
Conclusion

In conclusion, we have shown that calix[6]tris-acids 1 and 2 behave as remarkable hosts for ammonium ions under experimental conditions for which the calix[6]tris-ester and tris-amide derivatives are inefficient. In particular, the inclusion of large biological ammonium ions was achieved with the calix[6]tris-acid 2 which possesses an open cavity. As evidenced through NMR studies and a X-ray structure, the preorganization of the molecular receptors in a well-defined rigid cone conformation takes place thanks to the self-assembly of a supramolecular cap that closes the narrow rim of the calixarene and thus provides a suitable interaction site for ammonium ions. This required cap is formed through the association of the terminal carboxylate or carboxylic groups and exo-ammonium ions via hydrogen bonding and ion-paired interactions. The X-ray structure of an host-guest complex showed, on one hand, a remarkable $C_3$-complementarity between the well-organized binding carboxylates of the host and the ammonium guest and, on the other hand, a cooperative tail-to-tail dimeric self-assembly of two calixarenes subunits. The host-guest adducts possessing an ion-paired cap revealed to be highly stable in polar and protic solvents. Finally, the assembly of the cap was also performed with a bulky ammonium ion unable to enter into the cavity. In this case, it led to molecular receptors able to respond, through a very selective process, to only one equivalent of an ammonium ion present in solution. All this work highly contributes to the rationalization of ammonium ions complexation by macrocyclic receptors in organic media. In addition, it shows the efficiency of the calix[6]arene platform, along with ionic interactions, for the recognition of ammonium ions in protic media and thus opens interesting perspectives for the elaboration of sensors for bioactive ammonium ions in aqueous media as well as self-assembled nano-size objects.
Experimental Section

General Experimental Methods: CHCl₃ was distilled over P₂O₅ under argon. All reactions were performed under an inert atmosphere. ¹H and ¹³C NMR spectra were recorded at 300 and 75 MHz respectively. Chemical shifts are expressed in ppm. J values are given in Hz. Traces of residual solvent were used as internal standard. IR spectra were recorded on a Perkin-Elmer IRFT Paragon 1000 apparatus. Elemental analyses were performed at the Laboratoire de Microanalyse Organique (IRCOF, Mont Saint Aignan, France). Calix[6]tris-acids 1 and 2 were prepared according to the literature.¹⁵,¹⁶

1⁻³H+,³tBuNH₃⁺. Calix[6]tris-acid 1 (30 mg, 0.025 mmol) was dissolved in CHCl₃ (0.4 mL) and tBuNH₂ (16 µL, 0.15 mmol) was added. After 5 min of stirring at room temperature, Et₂O (1 mL) was added and the resulting precipitate was isolated by centrifugation, washed with Et₂O (2 x 0.2 mL) and then dried over vacuum to yield 1⁻³H+,³tBuNH₃⁺ (29 mg, 82 %) as a white solid. mp: 270 °C; (Found: C, 70.1; H, 9.3; N, 2.6. Calc. for C₇₅H₉₃O₁₂,3C₄H₁₂N,4.5H₂O: C, 70.1; H, 9.3; N, 2.8%); υ_{max}(KBr)/cm⁻¹ 3680 to 3120, 1694, 1595, 1482, 1415; δH(300 MHz; CDCl₃) 0.85 (27 H, s, tBu_calix), 1.30 (27 H, s, tBu_calix), 1.40 (27 H, s, tBu_NH₃⁺), 2.41 (9 H, br s, OMe), 3.42 (6 H, d, J₁₅=A₁₅), 4.45 (6 H, s, OCH₂), 4.50 (6 H, d, J₁₆=A₁₆), 6.91 (6 H, s, ArH), 7.18 (6 H, s, ArH). δC(75 MHz; CDCl₃) 28.1, 29.9, 31.1, 31.5, 34.0, 34.2, 51.5, 60.6, 124.2, 127.9, 132.7, 133.4, 146.1, 146.3, 151.2, 153.7, 174.3.

2⁻³H+,³tBuNH₃⁺. Calix[6]tris-acid 2 (30 mg, 0.026 mmol) was dissolved in CHCl₃ (1 mL) and tBuNH₂ (55 µL, 0.52 mmol) was added. After 30 min of stirring at room temperature, the solution was concentrated to dryness under reduced pressure. The resulting solid was washed with Et₂O (2 x 0.2 mL) and then dried over vacuum to yield 2⁻³H+,³tBuNH₃⁺ (35 mg, 98 %) as a beige solid. mp: 160 °C (decomp.); (Found: C, 58.0; H, 6.8; N, 5.7. Calc. for C₆₃H₆₆N₃O₁₈,3C₄H₁₂N,CHCl₃,4H₂O: C, 58.25; H, 7.1; N, 5.4%); υ_{max}(KBr)/cm⁻¹ 3700 to
3160, 1700 to 1550, 1480, 1405, 1344; \( \delta_{\text{H}} \) (300 MHz; CDCl\(_3\)) 1.32 (27 H, s, \( t^\text{Bu}_\text{NH}_3^+ \)), 1.39 (27 H, s, \( t^\text{Bu}_\text{calix} \)), 3.52 (6 H, d, J 16, ArCH\(_{eq}\)), 3.80 (9 H, s, OMe), 4.16 (6 H, br s, OCH\(_2\)), 4.57 (6 H, d, J 15, ArCH\(_{ax}\)), 7.18 (12 H, s, ArH).

**X-ray structure determination of complex 1\(^{-3}\text{H}^+,2\text{EtNH}_3^+\rightarrow\text{EtNH}_3^+\).** Diffraction data were measured on a Bruker-Nonius KappaCCD diffractometer.\(^{28}\) Crystals were unstable upon standing to air and were rapidly fished out from their mother liquor using a cryoloop and frozen under a cold nitrogen stream. Data sets consist of 180 frames, 1 degree-rotation each (exposure time: 60 s per frame). Frames were processed using the DENZO/HKL package.\(^{29}\) The structures were solved by direct methods and refined using SHELXL.\(^{30}\) Refinement details: the complex co-crystallized with highly disordered solvent molecules which were modelled as two ether molecules with occupancy equal to 0.5 and 0.7 respectively and one water molecule with occupancy 0.3. Two \( \text{t}^\text{ert} \)-butyl groups were also splitted on two sites because of static disorder with occupancy equal to 0.3 and 0.7 respectively for the two sites of one \( \text{t}^\text{ert} \)-butyl and occupancy equal to 0.4 and 0.6 respectively for the two sites of the second \( \text{t}^\text{ert} \)-butyl. All hydrogen atoms were introduced in the calculation with their isotropic thermal factor riding on that of the bonded atom but not refined. Those of the disordered \( \text{t}^\text{ert} \)-butyl groups were omitted from the calculation as well as those of the disordered ether and water molecules. Crystal data: C\(_{86.8}\)H\(_{130.6}\)Cl\(_3\)O\(_{13.5}\)N\(_3\), \( \text{M}_w = 1538.49 \), monoclinic, colorless crystal (0.4 \( \times \) 0.3 \( \times \) 0.2 mm\(^3\)), \( a = 19.8304(2) \) Å, \( b = 18.5246(2) \) Å, \( c = 30.4264(3) \) Å, \( \beta = 123.3431(5)^\circ \), \( V = 9337.32(17) \) Å\(^3\), space group P 2\(_1\)/c, \( Z = 4 \), \( \rho = 1.094 \) g cm\(^{-3}\), \( \mu(\text{MoK}\alpha) = 1.55 \) cm\(^{-1}\), 70626 reflections measured at 223 K in the 0.8-28.56\(^\circ\) 0 range, 23109 unique, 1039 parameters refined on \( F^2 \) to final indices R[12181 refl. : \( F^2>4\sigma(F^2) \)] = 0.1362, wR[23109 refl.] = 0.4066 [\( w = 1/[(\sigma^2(\text{Fo})+(0.1777P)^2+21.7766P)/3] \)]. The last residual Fourier positive and negative peaks were equal to 1.115 and -0.605 respectively.

The CIF file for the X-ray structure of $\text{1}^{\cdot}\text{3H}^+,\text{2EtNH}_3^+ \supset \text{EtNH}_3^+$ has been deposited at the CCDC with entry number CCDC 299787. NOESY spectrum of $\text{1}^{\cdot}\text{3H}^+,\text{2PrNH}_3^+ \supset \text{PrNH}_3^+$, $^1\text{H}$ NMR spectra of $\text{1}^{\cdot}\text{3H}^+,\text{3tBuNH}_3^+ \supset \text{PrNH}_3^+$ (CDCl$_3$, 294 K), $\text{1}^{\cdot}\text{3H}^+,\text{2PrNH}_3^+ \supset \text{PrNH}_3^+$ (CDCl$_3$, 294 K), $\text{1}^{\cdot}\text{3H}^+,\text{2tBuNH}_3^+ \supset \text{PrNH}_3^+$ (CDCl$_3$, 294 K), $\text{2}^{\cdot}\text{3H}^+,\text{2PrNH}_3^+ \supset \text{PrNH}_3^+$ (CD$_3$OD, 260 K), $\text{2}^{\cdot}\text{3H}^+,\text{2tBuNH}_3^+ \supset \text{PrNH}_3^+$ (CD$_3$OD, 295 K), $\text{1} + \text{PIPNH} \supset \text{PrNH}_3^+$ (CDCl$_3$, 260 K), $\text{2}^{\cdot}\text{3H}^+,\text{2tBuNH}_3^+ \supset \text{PrNH}_3^+$ (CDCl$_3$, 294 K), $\text{1}^{\cdot}\text{3H}^+,\text{2tBuNH}_3^+ \supset \text{PrNH}_3^+$ (CDCl$_3$, 294 K), $\text{2}^{\cdot}\text{3H}^+,\text{2tBuNH}_3^+ \supset \text{PrNH}_3^+$ (CDCl$_3$, 294 K), $\text{1} + \text{PIPNH} \supset \text{PrNH}_3^+$ (CDCl$_3$, 260 K), $\text{2}^{\cdot}\text{3H}^+,\text{2PIPNH}_2^+ \supset \text{PrNH}_3^+$ (CDCl$_3$, 260 K) and the procedure for the determination of the association constant of PrNH$_3^+$ toward $\text{1}^{\cdot}\text{3H}^+,\text{2tBuNH}_3^+$.

Acknowledgments. We thank Pr. Olivia Reinaud for helpful discussions. Part of this work was supported by the French Ministry of Research and New Technologies.

Resonances at $\delta_{\text{CH}_2\text{N}} = 3.22$ and 3.03 ppm (for $R'$ = Et and Pr respectively) clearly indicate the presence of one equivalent of exo-$R'\text{NH}_3^+$. Since the *in* and *out* exchange of the ammonium ion is slower than the NMR time scale at 294 K, the host-guest complex should possess a high $K_{\text{ass}}$ value.
Similarly, the NH$_3^+$ signal of the included guests was down-field shifted. This is in good agreement with an increasing acidity of the ammonium group of the guests upon a total deprotonation of the hosts.

20 In the case of the propylammonium ion, a NOESY experiment confirmed that the high-field peaks belong to a guest PrNH$_3^+$ and allowed us to attribute all the resonances of the guest (See the Supporting Information).

21 It is noteworthy that, at low temperature, no endo-complexation of small neutral polar molecules (*i.e.* EtOH, DMF or imidazolidin-2-one) was observed with 1 or 1$^3$H$_3$+ (formed by addition of 3 equiv. of the bulky tBuNH$_2$), showing that these hosts include ammonium guests specifically.

22 An additional hydrogen bond involving a carboxylate group and a molecule of CHCl$_3$ is observed in the X-ray structure. Hence, the stabilization of the dimeric self-assembly takes place through a network of 20 hydrogen bonds.

23 The CIS values were determined after addition of an excess of the free amine R'NH$_2$ into a CDCl$_3$ solution of the calixarene host (*i.e.* 1 or 2). CIS were defined as $\Delta\delta = \delta(\text{complexed ammonium ion}) - \delta(\text{free amine})$.

24 It is noteworthy that the chirality of the racemic guest is not sensed by the calixarene core, since the host-guest adduct displays a $C_{3v}$ symmetrical NMR pattern.

25 The NMR pattern of the calixarene core of 2$^3$H$_3$+PIP$_2$NH$_2^+$ reveals to be dissymmetric at 294 K (see the Supporting Information) but reflects a pseudo-$C_{3v}$ symmetry at 330 K. It may be rationalized by a slow exchange (compared to the NMR time scale) of this bulky secondary ammonium ion between the three binding carboxylates.
The NMR studies of their stability were conducted in DMSO-d$_6$ at 294 K after addition of a slight excess of PrNH$_2$ (5 equiv.) to 1 and 2 and in CD$_3$OD at 260 K after addition of an excess of PrNH$_2$ (ca. 20 equiv.) to 1 and 2.

The $^1$H NMR spectra of $^1$-3H+,3tBuNH$_3^+$ and $^2$-3H+,3tBuNH$_3^+$, recorded upon similar conditions (CDCl$_3$, 294 K, 3.5 mM), show that these compounds possess opposite flattened cone conformation. Indeed, in contrast to $^2$-3H+,3tBuNH$_3^+$ (Figure 4a), the methoxy groups of $^1$-3H+,3tBuNH$_3^+$ are directed toward the inside of the cavity.

Stéphane Le Gac,\textsuperscript{a} Michel Giorgi\textsuperscript{b} and Ivan Jabin\textsuperscript{a,*}

Fig. S1. NOESY (CDCl$_3$, 294 K) spectrum of $1^\text{-}^{3}\text{H}^+,2\text{PrNH}_3^+\supset\supset\supset\supset\supset\supset\supset\supset\supset\supset\Pr\text{NH}_3^+$. 
Fig. S2. $^1$H NMR spectra (300 MHz, CDCl$_3$) at 294 K: (a) $\text{1}^{-3}\text{H}^+,3\text{tBuNH}_3^+$; (b) $\text{1}^{-3}\text{H}^+,2\text{tBuNH}_3^+$ obtained upon the addition of one equiv. of PrNH$_2$ to $\text{1}^{-3}\text{H}^+,3\text{tBuNH}_3^+$. ▼: included PrNH$_3^+$. Residual solvent and water have been labeled "S" and "W" respectively.

**Determination of the association constant (Kass) of PrNH$_3^+$ toward $\text{1}^{-3}\text{H}^+,2\text{tBuNH}_3^+$.**

This constant was estimated to be at least 1.2 x 10$^5$ M$^{-1}$ based on the following equilibrium:

$$
\text{1}^{-3}\text{H}^+,3\text{tBuNH}_3^+ + \text{PrNH}_2 \rightleftharpoons \text{1}^{-3}\text{H}^+,2\text{tBuNH}_3^+ \supset \supset \text{PrNH}_3^+
$$

As the $^1$H NMR spectrum of a 1:1 mixture of $\text{1}^{-3}\text{H}^+,3\text{tBuNH}_3^+$ and PrNH$_2$ revealed the formation of $\text{1}^{-3}\text{H}^+,2\text{tBuNH}_3^+ \supset \text{PrNH}_3^+$ as the only observable species (see Fig. S2), the concentrations at the equilibrium of $\text{1}^{-3}\text{H}^+,3\text{tBuNH}_3^+$ and PrNH$_2$ have been estimated to be ≤ 0.05 x C$_0$ and the concentration of $\text{1}^{-3}\text{H}^+,2\text{tBuNH}_3^+ \supset \text{PrNH}_3^+$ has been estimated to be ≥ to 0.95 x C$_0$.

$$
\text{Kass} \geq \frac{[0.95 \times C_0]}{[0.05 \times C_0]^2}
$$

Thus, Kass ≥ 1.2 x 10$^5$ M$^{-1}$
Fig. S3. $^1$H NMR spectrum (300 MHz, DMSO-d$_6$) at 296 K of $[^{3}\text{H}_3,2\text{PrNH}_3]^+\text{PrNH}_3^+\supseteq\text{PrNH}_3^+$. ▼: free PrNH$_2$. Residual solvent and water have been labeled "S" and "W" respectively.
Fig. S4. $^1$H NMR spectrum (300 MHz, CD$_3$OD) at 260 K of $2^{-3}\text{H}^+\cdot\text{PrNH}_3^+\supset\supset\supset\text{PrNH}_3^+$. ▼: free PrNH$_2$. Residual solvent, reference (1,1,2,2-tetrachloroethane) and water have been labeled "S", "R" and "W" respectively.
