Estimating the order of vanishing at infinity of Drinfeld quasi-modular forms.

Federico Pellarin
September 26, 2010

Abstract. We introduce and study certain deformations of Drinfeld quasi-modular forms by using rigid analytic trivialisations of corresponding Anderson’s t-motives. We show that a sub-algebra of these deformations has a natural graduation by the group $\mathbb{Z}^2 \times \mathbb{Z}/(q-1)\mathbb{Z}$ and an homogeneous automorphism, and we deduce from this and other properties multiplicity estimates.

1 Introduction, results.

Let $E_4, E_6$ be the Eisenstein series of weights 4, 6 respectively, rescaled so that they have limit 1 as the imaginary part of the variable tends to infinity; let us denote by $M$ the two-dimensional $\mathbb{C}$-algebra $\mathbb{C}[E_4, E_6]$. We have $M = \oplus_w M_w$, where $M_w$ denotes the $\mathbb{C}$-vector space of classical modular forms $SL_2(\mathbb{Z})$ of weight $w$.

Let $E_2$ be the so-called “false” Eisenstein series of weight 2 (rescaled), and let us consider, for $l, w$ non-negative integers with $w > 0$ even, the non-zero finite dimensional $\mathbb{C}$-vector space $\widetilde{M}^{\leq l}_w = M_w \oplus M_{w-2} E_2 \oplus \cdots \oplus E_2^l M_{w-2l}$ of classical quasi-modular forms of weight $w$ and depth $\leq l$.

The local behaviour at infinity of quasi-modular forms yields an embedding $\widetilde{M}^{\leq l}_w \to \mathbb{C}[q]$, where $q = e^{2\pi i z}$, $z \in \mathcal{H}$ being the variable in the complex upper-half plane. Let $f$ be in $\widetilde{M}^{\leq l}_w \setminus \{0\}$. Then, we may write $f = q^{\nu_\infty(f)} g$ with $g$ a unit of $\mathbb{C}[q]$, for an integer $\nu_\infty(f) \geq 0$ which is uniquely determined; this is the order of vanishing at infinity of $f$.

A simple resultant argument suffices to show that

$$\nu_\infty(f) \leq 3 \dim_{\mathbb{C}} \widetilde{M}^{\leq l}_w.$$  (1)
Now, let $q = p^e$ (1) be a power of a prime number $p$ with $e > 0$ an integer, let $\mathbb{F}_q$ be the finite field with $q$ elements. Let us write $A = \mathbb{F}_q[\theta]$ and $K = \mathbb{F}_q(\theta)$, with $\theta$ an indeterminate over $\mathbb{F}_q$, and define an absolute value $| \cdot |$ on $K$ by $|a| = q^{\deg a}$, $a$ being in $K$, so that $|\theta| = q$. Let $K_{\infty} := \mathbb{F}_q((1/\theta))$ be the completion of $K$ for this absolute value, let $K_{\text{alg}}$ be an algebraic closure of $K_{\infty}$, let $C$ be the completion of $K_{\text{alg}}$ for the unique extension of $| \cdot |$ to $K_{\text{alg}}$, and let $K_{\text{alg}}$ be the algebraic closure of $K$ in $C$.

Following Gekeler in [11], we denote by $\Omega$ the rigid analytic space $C \setminus K_{\infty}$ and write $\Gamma$ for $\text{GL}_2(A)$, group that acts on $\Omega$ by homographies. In this setting we have three functions $E, g, h : \Omega \to C$, holomorphic in the sense of [9, Definition 2.2.1], such that, for all $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma$ and $z \in \Omega$:

\[
\begin{align*}
g(\gamma(z)) &= (cz + d)^q g(z), \\
h(\gamma(z)) &= (cz + d)^{q+1} \det(\gamma)^{-1} h(z), \\
E(\gamma(z)) &= (cz + d)^2 \det(\gamma)^{-1} \left( E(z) - \frac{e}{\tilde{\pi}(cz + d)} \right) \quad (2)
\end{align*}
\]

where $\gamma(z) = (az + b)/(cz + d)$ and $\tilde{\pi}$ is a fundamental period of Carlitz module, defined by the convergent product:

\[
\tilde{\pi} := \theta(-\theta)^{-\frac{1}{q^2}} \prod_{i=1}^{\infty} (1 - \theta^{1-q^i})^{-1} \in K_{\infty}((-\theta)^{-\frac{1}{q^2}}) \setminus K_{\infty},
\]

a choice of a $(q - 1)$-th root of $-\theta$ having been made once and for all (2).

The functional equations above tell that $g, h$ are Drinfeld modular forms, of weights $q - 1$, $q + 1$ and types 0, 1 respectively. For $w$ integer and $m \in \mathbb{Z}/(q - 1)\mathbb{Z}$, we denote by $M_{w,m}$ the $C$-vector space of Drinfeld modular forms of weight $w$ and type $m$.

After [2], the function $E$ is not a Drinfeld modular form. In [11], Gekeler calls it “False Eisenstein series” of weight 2 and type 1; it is easy to show that $E, g, h$ are algebraically independent. For $l, w$ non-negative integers and $m$ a class of $\mathbb{Z}/(q - 1)\mathbb{Z}$, we introduce the $C$-vector space of Drinfeld quasi-modular forms of weight $w$, type $m$ and depth $\leq l$:

\[
\tilde{M}_{w,m}^{\leq l} = M_{w,m} \oplus M_{w-2,m-1} E \oplus \cdots \oplus M_{w-2l,m-l} E^l.
\]

Let $\epsilon_{\text{car}} : C \to C$ be the Carlitz exponential function (see below, [13]) and let us write $u : \Omega \to C$ for the “parameter at infinity” of $\Omega$, that is, the function $u(z) = 1/\epsilon_{\text{car}}(\tilde{\pi} z)$; the $C$-algebra $\tilde{M}$ embeds in $C[[u]]$ (cf. [11]).

If $w, m, l$ are such that the finite dimensional vector space $\tilde{M}_{w,l}^{\leq l}$ does not vanish, any $f$ non-zero in $\tilde{M}_{w,l}^{\leq l}$ can be written, for $u = u(z)$, as $f(z) = u^{\nu_{\infty}(f)} \phi$ with $\phi$ a unit of the ring $C[[u]]$ (convergence when $|u|$ is small enough) for some non-negative integer $\nu_{\infty}(f)$ uniquely determined; the order of vanishing at infinity of $f$.

The aim of this paper is to prove the following analog of [11]:

**Theorem 1** Let $l$ be a positive integer. There exist two constants $c_1, c_2$, with $c_1$ depending on $l, q$ and $c_2$ depending on $q$, with the following property. If $w \geq c_1$ and $M_{w,m}^{\leq l} \neq (0)$ then, for all $f \in \tilde{M}_{w,m}^{\leq l} \setminus \{0\}$,

\[
\nu_{\infty}(f) \leq c_2 \dim C \tilde{M}_{w,m}^{\leq l}.
\]

---

1 The double use of the letter $q$ in this paper will not be a source of confusion; other harmless abuses of notation will appear in this paper.

2 See [21 Section 2.1], where the notation $\exists$ is adopted; there is an analogy with the number $2\pi i$. 

---

2
Our result is completely explicit; if $l > 0$ and $f \in \tilde{M}_{w,m}^{\leq l}$ is a non-zero Drinfeld quasi-modular form, we will prove that
\[ \nu_{\infty}(f) \leq 16q^3(3 + 2q)^2lw, \tag{3} \]
provided that
\[ w \geq 4l(2q(q + 2)(3 + 2q)l + 3(q^2 + 1))^{3/2}, \tag{4} \]
which obviously implies the Theorem by a simple computation of the dimension of $\tilde{M}_{w,m}^{\leq l}$.

In [3] we conjectured that for all $z \in \Omega$ at least three of the four numbers $u(z), E(z), g(z), h(z)$ are algebraically independent over $K$. If true, this statement would be an analog of Nesterenko’s celebrated theorem on the algebraic independence of values of Eisenstein’s series and the parameter at infinity (see [18, Chapter 3, Theorem 1.1] and [17]). In the attempt of proving this conjecture, it turned out very difficult to adopt Nesterenko’s original scheme of proof. Indeed, Drinfeld quasi-modular forms, while sharing several superficial similarities with classical quasi-modular forms, essentially behave in a different way. The main difficulties encountered are the following:

Absolute values of coefficients of $u$-expansions of Drinfeld quasi-modular forms grow “too rapidly” depending on the index; if $f = \sum c_i u^i$ is such a form, then the estimate $|c_i| \ll e^{c_i}$ is best possible (in the classical case, we would have $|c_i| \ll i^c$).

The algebra $\tilde{M}$ is endowed with higher derivatives (this was studied in the joint work [3]); however, this structure alone does not seem to easily deliver a suitable analogue of the separation property [5, Lemma, p. 212], useful for multiplicity estimates in differential algebras.

These difficulties suggest that the algebra $\tilde{M}$ is not an appropriate environment to study the arithmetic of values of Drinfeld quasi-modular forms. Theorem [1] could superficially look like a mere copy of the elementary inequality (3). Before our proof, it was however very resistant to any attempt to prove it. The main motivation of this paper is to find new structures allowing to prove Theorem [1].

In this paper, we introduce a new class of functions (deformations of Drinfeld quasi-modular forms), endowed with certain automorphic properties and a “Frobenius structure”. The theory we introduce is strongly influenced by that of Anderson’s $t$-motives. The idea of appealing to Anderson’s theory is very natural; however, a new entity occurs here, making this paper useful: the functions we deal with have automorphic properties; they generate an algebra graded by the group $\mathbb{Z}^2 \times \mathbb{Z}/(q - 1)\mathbb{Z}$. Similar objects in the classical theory do not seem to be already known.

The main properties of our functions are listed in Proposition [2] below for the sake of commodity (this proposition will not be applied directly). With the help of all these properties and a transcendence proof, we deduce Theorem [1].

In order to present Proposition [2] we require some further preparation.

Let $t$ be an independent indeterminate, let us temporarily denote by $\mathbb{T}$ the subring of formal series of $C[[t]]$ converging for all $t \in C$ such that $|t| < r$ for a certain real number $r > q$ (3). In Section [3] we will construct a function
\[ E : \Omega \to \mathbb{T} \]
such that, for $t \in C$ and $z \in \Omega$ with $|t|$ and $|u|$ small enough (and with $u = u(z)$), the value $E(z)(t)$ is that of a convergent double series in $C[[t, u]]$. More precisely, we will show (Proposition

---

3 Later, we will see that $r \geq q^d$ and we will then use the notation $\mathbb{T}_{< q^d}$. 

---
the existence of polynomials $c_i \in \mathbb{F}_q[t, \theta]$ such that there is a locally convergent expansion
\[
E(z)(t) = u \sum_{i \geq 0} c_i(t) u^{i(q-1)} \in u \mathbb{F}_q[t, \theta][[u^{q-1}]].
\] (5)

We identify $E$ with the formal series at the right-hand side of (5).

We will use the following extension of Anderson’s $\mathbb{F}_q[t]$-linear map $\tau : C[[t, u]] \rightarrow C[[t, u]]$:
\[
\tau \sum_{m,n \geq 0} c_{m,n} t^m u^n := \sum_{m,n \geq 0} c^{\tau}_{m,n} t^m u^{qn}
\]
the $c_{m,n}$’s being in $C$.

Let $F$ be the formal series $\tau E \in u \mathbb{F}_q[t, \theta][[u^{q(q-1)}]]$, it converges locally at $(0, 0)$, and extends to a well defined function $\Omega \rightarrow \mathbb{T}$. Let us denote by $M^\dagger$ the algebra $\mathbb{T}[g, h, E, F]$, that we will often identify with its image in $C[[t, u]]$. We have the following Proposition (4):

**Proposition 2** The algebra $M^\dagger \subset C[[t, u]]$ enjoys the following properties.

1. The dimension of $M^\dagger$ is four, so that the formal series $g, h, E, F$ are algebraically independent over $C((t))$ and define a basis of $M^\dagger$.
2. The basis $(g, h, E, F)$ of $M^\dagger$ above is constituted by formal series in $\mathbb{F}_q[t, \theta][[u]]$ (it is integral over $\mathbb{F}_q[t, \theta]$).
3. The algebra $M^\dagger$ is graded by the group $G = \mathbb{Z}^2 \times \mathbb{Z}/(q-1)\mathbb{Z}$. In other words, $M^\dagger = \bigoplus_{(\mu, \nu, m) \in G} M^\dagger_{\mu, \nu, m}$. We further have $M^\dagger_{0,0,0} = \mathbb{T}$ and $M^\dagger_{0,0,m} = M_{\mu, \nu} \otimes_C \mathbb{T}$. For this graduation, the “degrees” of $g, h, E$ and $F$ are respectively the following elements of $G$: $(q - 1, 0, 0), (q + 1, 0, 1), (1, 1, 1)$ and $(q, 1, 1)$.
4. For any $f \in M^\dagger_{\mu, \nu, m}$, the formal series $\varepsilon(f) = f|_{t=\theta}$ is a well defined Drinfeld quasi-modular form of $M_{\mu, \nu, m} \leq \mu$, and we have a surjective $C$-linear map $\varepsilon : M^\dagger \rightarrow M$ such that $\varepsilon(E) = E$; in this sense, $E$ is a deformation of $E$.
5. The algebra $M^\dagger$ is stable under the action of $\tau$: more precisely, $\tau$ induces $\mathbb{F}_q[t]$-linear maps $M^\dagger_{\mu, \nu, m} \rightarrow M^\dagger_{\mu', \nu', m'}$.
6. Let $f$ be in $M^\dagger$, let us assume that $f = \sum_{i \geq 0} c_i u^i$ with $c_i \in \mathbb{F}_q[t, \theta]$. Then, $\deg E c_i \leq c \log i$ where $c$ is a constant depending on $f$ only.

The properties described in Proposition 2 a variant of Siegel’s Lemma (Proposition 52) and a transcendence construction will be used to prove Theorem 11.

### 2 Anderson’s functions

As $A$-lattice of rank $r > 0$ we mean a free sub-$A$-module of $C$ of rank $r$, discrete in the sense that, given a compact subset of $C$, only finitely many elements of it lie in. Let $A \subset C$ be

---

It results from the combination of the six Propositions [9, 10, 11, 20, 21] and [24] and elementary considerations. The Proposition is stated to ease the access of the paper, but later, we will require the full statement of the six propositions above. Throughout these six propositions, many other properties of the functions $E, F$ and of the algebra $M^\dagger$ will be highlighted.
an $A$-lattice of rank $r$ and let us consider, for $\zeta \in C$, the exponential function associated to $\Lambda$, defined by the product:

$$e_\Lambda(\zeta) := \zeta \prod_{\omega \in \Lambda \setminus \{0\}} \left(1 - \frac{\zeta}{\omega}\right),$$

(6)

which converges for all $\zeta \in C$. For $\lambda \in C^\times$, the product expansion (6) implies:

$$e_{\lambda \Lambda}(\zeta) = \lambda e_\Lambda(\lambda^{-1} \zeta).$$

(7)

There exist elements $1 = \alpha_0(\Lambda), \alpha_1(\Lambda), \alpha_2(\Lambda), \ldots \in C$, depending on $\Lambda$ only, such that:

$$e_\Lambda(\zeta) = \sum_{n \geq 0} \alpha_n(\Lambda) \zeta^n,$$

(8)

the series having infinite radius of convergence (cf. \cite{[1]} \cite{[13]}).

The construction of the exponential function by (6) is the main tool to prove that the category whose objects are homothecy classes of $A$-lattices of rank $r$ and morphisms are inclusions, is dually equivalent to the category whose objects are isomorphism classes of Drinfeld $A$-modules of rank $r$ and morphisms are isogenies (see \cite{[1]} Section (2.6) or \cite{[21]} Section 2). For $\Lambda$ as above, there is a Drinfeld $A$-module $\phi_\Lambda$ such that

$$\phi_\Lambda(\alpha)e_\Lambda(\zeta) = e_\Lambda(a\zeta)$$

(9)

(for all $\zeta \in C$ and $a \in A$), which is uniquely determined by its value $\phi_\Lambda(\theta) \in \textbf{End}_{\text{alg.}}(G_\mathfrak{a}(C))$ in $\theta$. This value is a polynomial of degree $r$ in $\tau$, which we recall, is the Frobenius endomorphism $\tau : c \mapsto c^q$. On the other side, to any Drinfeld $A$-module $\phi$ of rank $r$, a lattice $\Lambda_\phi$ of rank $r$ can be associated, so that the functors $\Lambda \mapsto \phi_\Lambda$ and $\phi \mapsto \Lambda_\phi$ are inverse of each other up to isomorphisms.

Let $t$ be a new indeterminate. With $\Lambda$ an $A$-lattice of rank $r > 0$ and $e_\Lambda$ as in (6), let us consider $\omega \in \Lambda \setminus \{0\}$ and introduce, following Anderson in \cite{[1]} the formal series:

$$s_{\Lambda, \omega}(t) := \sum_{i=0}^{\infty} e_\Lambda(\frac{\omega}{q^{i+1}}) t^i.$$

(10)

For a positive real number $r$, we denote by $\mathbb{T}_{<r}$ the sub-$C$-algebra of $C[[t]]$ whose elements are formal series $\sum_{n \geq 0} c_n t^n$ that converge for any $t \in C$ with $|t| < r$. We denote by $\mathbb{T}_{>0}$ the sub-$C$-algebra of $C[[t]]$ whose series converge in some open disk containing 0, and we notice that all the series of $\mathbb{T}_{<q^r}$ converge at $t = \theta$. We also denote by $\mathbb{T}_{\infty}$ the sub-$C$-algebra of series that converge everywhere in $C$.

If $r_1 > r_2 > 0$, we have

$$\mathbb{T}_{>0} \supset \mathbb{T}_{<r_2} \supset \mathbb{T}_{<r_1} \supset \mathbb{T}_{\infty}.$$

The Tate algebra of formal series of $C[[t]]$ converging for all $t$ such that $|t| \leq 1$ will be denoted by $\mathbb{T}$; it is contained in $\mathbb{T}_{<1}$ and contains $\mathbb{T}_{<1+\epsilon}$ for all $\epsilon > 0$.

It is easy to verify that, with $\Lambda$ and $\omega \in \Lambda$ as above, $s_{\Lambda, \omega} \in \mathbb{T}_{<q} \subset \mathbb{T}$. If $\Lambda \subset K_{\infty}^{\text{alg.}}$, it can be proved that $s_{\Lambda, \omega}(t) \in K_{\infty}^{\text{alg.}}[[t]]$.

We extend the operator $\tau$ from $C$ to $C[[t]]$ as follows:

$$f = \sum_{n \geq 0} c_n t^n \mapsto \tau f := \sum_{n \geq 0} c_{\tau n} t^n.$$
We will also write \( f^{(k)} \) for \( \tau^k f, k \in \mathbb{Z} \) (the operator \( \tau^{-1} \) is well defined). One checks that \( \tau \) sends \( \mathbb{T}_{< r} \) to \( \mathbb{T}_{< r^a} \). The extension \( \tau \) so constructed defines \( \mathbb{F}_q \)-automorphisms of \( \mathbb{T}_{> 0} \). If \( \Lambda \) is an \( A \)-lattice of rank \( r \) and if \( \phi_\Lambda \) is the Drinfeld \( A \)-module of rank \( r \) in \([9]\), then, for all \( a_1, a_2 \in A \) and \( \omega_1, \omega_2 \in \Lambda \),
\[
\phi_\Lambda(a_1) s_{\Lambda, \omega_1} + \phi_\Lambda(a_2) s_{\Lambda, \omega_2} = s_{\Lambda, a_1 \omega_1 + a_2 \omega_2} = \overline{a}_1 s_{\Lambda, \omega_1} + \overline{a}_2 s_{\Lambda, \omega_2}.
\]
(10)

These identities, which hold in \( \mathbb{T} \), are proved in \([21]\) Section 4.2.2.

From \([7]\) it immediately follows that, for \( \lambda \in C^\times \),
\[
s_{\Lambda, \omega}(t) = \lambda s_{\Lambda, \omega}(t).
\]
(11)

We also have the series expansion (cf. \([21]\) Section 4.2.2)
\[
s_{\Lambda, \omega}(t) = \sum_{n=0}^{\infty} \frac{\alpha_n(\Lambda) \omega^n}{\theta \theta^n - t},
\]
(12)

uniformly convergent in every compact subset of \( C \setminus \{\theta, \theta^q, \ldots\} \), and \( s_{\Lambda, \omega}(t) - \omega/(\theta - t) \) extends to a rigid holomorphic function for \( |t| < q^a \). We will then often say that \( s_{\Lambda, \omega} \) has a simple pole of residue \(-\omega\) in \( t = \theta \). Notice that other poles occur at \( t = \theta^q, \theta^{q^2}, \ldots \), but we will never need to focus on them in this paper.

**Example: rank one case.** For \( \Lambda = \overline{\pi} A \) (rank 1), the exponential function \((8)\) is:
\[
e_{\text{Car}}(\zeta) = \sum_{n \geq 0} \zeta^n \frac{q^n}{d^n},
\]
(13)

where \( d_0 := 1 \) and \( d_i := [i][i−1]q \cdots [1]q^{i−1} \), recalling that \([i] = \theta^i − \theta \) if \( i > 0 \). The relations \([9]\) become, for all \( a \in A \),
\[
\phi_{\text{Car}}(a) e_{\text{Car}}(\zeta) = e_{\text{Car}}(a \zeta),
\]
where \( \phi_{\text{Car}} \) is Carlitz’s module defined by
\[
\phi_{\text{Car}}(\theta) = \theta t^a + \tau \in \textbf{End}_{\mathbb{F}_q \text{-lim.}}(G_a)
\]
(see Section 4 of \([11]\)).

We will write \( s_{\text{Car}} = s_{A, \overline{\pi}} \). The function \( s_{\text{Car}} \) has a simple pole in \( \theta \) with residue \(-\overline{\pi}\).

By \((10)\) (cf. \([21]\) Section 4.2.5)), the following \( \tau \)-difference equation holds:
\[
s^{(1)}_{\text{Car}}(t) = (t - \theta) s_{\text{Car}}.
\]
(14)

After \([9]\) Theorem 2.2.9, \( \mathbb{T} \) is a principal ideal domain. This property can be used to verify that the subfield of constants \( L^\tau := \{l \in L, \tau l = l\} \), where \( L \) is the fraction field of \( \mathbb{T} \), is equal to \( \mathbb{K} := \mathbb{F}_q(\theta) \) (see also \([14]\) Lemma 3.3.2)). We deduce, just as in the proof of \([14]\) Lemma 3.3.5), that the \( \tau \)-difference equation \( f^{(1)} = (t - \theta)f \) has, as a complete set of solutions in \( L \), the \( \mathbb{F}_q(t) \)-vector space \( \mathbb{F}_q(t)s_{\text{Car}} \). In fact, for all \( a = a(\theta) \in A \), we have \( s_{\overline{\pi}, A, \overline{\pi}} = \overline{a}s_{\text{Car}} \).

Comparing with \([13]\) we also point out, for further references in this paper, that \((12)\) becomes in this case:
\[
s_{\text{Car}}(t) = \sum_{n=0}^{\infty} \frac{\overline{\pi} q^n}{d_n(\theta \theta^n - t)}, \ \ |t| < q.
\]
(15)
2.1 Anderson’s functions for elliptic Drinfeld modules

We recall and deepen some tools described in [21] Section 4.2.5 (see also [8, 19]). Let \( z \) be in \( \Omega \), and consider the \( A \)-lattice \( \Lambda = \Lambda_z = A + zA \) of rank 2, with associated exponential function \( e_z = e_\Lambda \). Let us consider the Drinfeld module \( \phi_z \) defined by

\[
\phi_z : \theta \mapsto \phi_z(\theta) = \theta z^0 + \tilde{g}(z)z^1 + \tilde{\Delta}(z)z^2,
\]

where \( \tilde{g}(z) = \tilde{\pi}q^{-1}g(z) \), \( \tilde{\Delta}(z) = \tilde{\pi}q^{-1}\Delta(z) \), with \( \Delta = -h^{-1} \). Then,

\[
\phi_z(a) e_z(\zeta) = e_z(a\zeta)
\]

for all \( a \in A \) and \( \zeta \in C \) ([11] Section 5, [21] Section 4.2.5), see also [19].

We can write, for \( \zeta \in C \),

\[
e_z(\zeta) = \sum_{i=0}^{\infty} a_i(z)\zeta^i,
\]

for functions \( a_i : \Omega \to C \) with \( a_0 = 1 \). By (17) we deduce, with the initial values \( a_0 = 1, a_{-1} = 0 \), the recursive relations

\[
a_i = \frac{1}{|i|} (\tilde{g}a_{i-1} + \tilde{\Delta}a_{i-2}^2), \quad i > 0.
\]

This implies that the function \( a_i(z) \) is a modular form of weight \( q^i - 1 \) and type 0 for all \( i \geq 0 \). There exist elements \( c_i,m \in C \) such that

\[
a_i(z) = \sum_{m \geq 0} c_i,m u^m, \quad i \geq 0,
\]

with convergence for \( z \in \Omega \) such that \( |u| \) is small enough. The following lemma tells that a non-zero disk of convergence can be chosen independently on \( i \).

**Lemma 3** We have, for some \( B > 0 \),

\[
c_{i,0} = \frac{1}{d_i} \tilde{\pi}^{q^{-1}}, \quad i \geq 0,
\]

and

\[
|c_{i,m}| \leq q^{-q^i}B^m, \quad (i, m \geq 0).
\]

**Proof.** Let us write \( \tilde{g} = \sum_{i \geq 0} \tilde{\gamma}_i u^i \) and \( \tilde{\Delta} = \sum_{i \geq 0} \tilde{\delta}_i u^i \) with \( \tilde{\gamma}_i, \tilde{\delta}_i \in C \). The recursive relations (19) imply, for \( i > 1, m \geq 0 \) and \( j, k \) non-negative integers:

\[
c_{i,m} = \frac{1}{|i|} \left( \sum_{j+qk=m} \tilde{\gamma}_j c_{i-1,k}^q + \sum_{j+q^2k=m} \tilde{\delta}_j c_{i-2,k}^{q^2} \right),
\]

from which we deduce at once (21) because \( \tilde{\gamma}_0 = \tilde{\pi}^{-1} \) and \( \tilde{\delta}_0 = 0 \).

We now need to provide upper bounds for the \( |c_{i,m}| \)'s, with explicit dependence on \( i, m \).

Looking at [11] Definition (5.7), (iii), there exists \( B \geq q \) such that, for all \( i \geq 0 \), \( \max \{ |\tilde{\gamma}_i|, |\tilde{\delta}_i| \} \leq B^i \). We know that \( a_0 = 1 \) and that \( |c_{1,m}| \leq q^{-q}B^m \). After induction and the equality \( |i| = q^i \) (\( i > 0 \)), we deduce (22).

In all the following, we shall write:

\[
s_1(z, t) = s_{\Lambda_z, 1}(t), \quad s_2(z, t) = s_{\Lambda_z, 1}(t).
\]
These are functions $\Omega \times B_q \to C$, where, for $r > 0$, $B_r$ is the set \{ $t \in C, |t| < r$ \}.

In fact the definition of the functions $s_{A,\omega}$ tells that $s_1, s_2 \in \text{Hol}(\Omega[[t]])$, where $\text{Hol}(\Omega)$ denotes the $C$-algebra of rigid holomorphic functions $\Omega \to C$. After [8] and [12] we see that, for any couple $(z, t) \in \Omega \times B_q$, the following convergent series expansions hold:

$$
s_1(z, t) = \sum_{i=0}^{\infty} \frac{\alpha_i(z)}{\theta^{q^i} - t},
$$

$$
s_2(z, t) = \sum_{i=0}^{\infty} \frac{\alpha_i(z)}{\theta^{q^i} - t}.
$$

Our notations stress the dependence on two variables $z \in \Omega, t \in B_q$. For these functions, we will also write, occasionally, $s_1(z), s_2(z)$, to stress the dependence on $z \in \Omega$. We can also fix $z \in \Omega$ and study the functions $s_1(z, \cdot), s_2(z, \cdot)$, or look at the functions $s_1(\cdot, t), s_2(\cdot, t) : \Omega \to \mathbb{T}_{<q}$ with formal series as values. In the next section, we provide the necessary analysis of the functions $s_1(z, \cdot), s_2(z, \cdot)$. Hence, we fix now $z \in \Omega$.

**2.1.1 The $s_i$’s as functions of the variable $t$, with $z$ fixed.**

At $\theta$, the functions $s_i(z, \cdot)$ have simple poles. Their respective residues are, according to Section 2, $-z$ for the function $s_1(z, \cdot)$ and $-1$ for $s_2(z, \cdot)$. Moreover, we have $s_1^{(1)}(z, \theta) = \eta_1$ and $s_2^{(1)}(z, \theta) = \eta_2$, where $\eta_1, \eta_2$ are the quasi-periods of $\Lambda_z$ (see [21] Section 4.2.4 and [10] Section 7).

Let us consider the matrix function:

$$
\tilde{\Psi}(z, t) := \begin{pmatrix} s_1(z, t) & s_2(z, t) \\ s_1^{(1)}(z, t) & s_2^{(1)}(z, t) \end{pmatrix}.
$$

By [21] Section 4.2.3 (see in particular equation (15)), we have:

$$
\tilde{\Psi}(z, t)^{(1)} = \tilde{\Theta}(z) \cdot \tilde{\Psi}(z, t), \quad \text{where} \quad \tilde{\Theta}(z) = \begin{pmatrix} 0 & 1 \\ t - \theta & \Delta(z) \end{pmatrix},
$$

yielding the following $\tau$-difference linear equation of order 2:

$$
s_2^{(2)} = \frac{t - \theta}{\Delta} s_2 - \frac{\bar{g}(z)}{\Delta} s_2^{(1)}.
$$

**Remark 4** By [1], there is a fully faithful contravariant functor from the category of Drinfeld $A$-modules over $K^{\text{alg}}$ to the category of Anderson’s $A$-motives over $K^{\text{alg}}$. Part of this association is sketched in [21] Section 4.2.2, where the definition of $A$-motive is given and discussed (see also [8]); it is based precisely on Anderson’s functions $s_{A,\omega}$. In the language introduced by Anderson, $\Psi$ is a rigid analytic trivialisation of the $A$-motive associated to the Drinfeld module $\phi = \phi_A$.

We will also use the following fundamental lemma, whose proof depends on Gekeler’s paper [10].

**Lemma 5** (“Deformation of Legendre’s identity”) We have, for all $z \in \Omega$ and $t$ with $|t| < q$:

$$
\det(\tilde{\Psi}) = \pi^{-1} q^{h(z)} \cdot s_{\text{Car}}(t).
$$
Proof. Let \( f(z,t) \) be the function \( \det(\tilde{\Psi}(z,t))h(z)\tilde{\pi}^{1+q} \), for \( z \in \Omega \) and \( t \in B_q \). We have:

\[
f^{(1)}(z,t) = -(t-\theta)\tilde{\Delta}(z)^{-1}\det(\tilde{\Psi}(z,t))h(z)\tilde{\pi}^{q+q^2} = (t-\theta)f(z,t).
\]

For fixed \( z \in \Omega \), we know that \( s_i^{(k)}(z,\cdot) \in \mathbb{T}_{<q^k} \subset \mathbb{T} \) for all \( k \geq 0 \). Hence, \( f(z,\cdot) \in \mathbb{T} \) for all \( z \in \Omega \). By arguments used in the remark on the \( \mathbb{K} \)-vector space structure of the set of solutions of (14), \( f(z,t) \) is equal to \( \lambda(z,t)s_{\text{Car}}(t) \), for some \( \lambda(z,t) \in \mathbb{K} \); the matter is now to compute \( \lambda \), which does not depend on \( z \in \Omega \) as it follows easily by fixing \( t = t_0 \in B_q \) transcendental over \( \mathbb{F}_q \) and observing that \( f(z,t_0) \) is holomorphic over \( \Omega \) with values in a discrete set.

Now, for \( z \) fixed as \( t \to \theta \),

\[
\lim_{t\to\theta} \tilde{\Psi}(z,t) - \left( \frac{-z}{\eta_1} \quad \frac{-1}{\eta_2} \right) = \left( \begin{array}{cc} * & * \\ 0 & 0 \end{array} \right),
\]

\( \eta_1, \eta_2 \) being the quasi-periods (periods of second kind) of the lattice \( A\omega_1 + A\omega_2 \) (respectively associated to \( \omega_1 \) and \( \omega_2 \)) [10] Section 7, Equations (7.1)], with generators \( \omega_1 = z, \omega_2 = 1 \), where the asterisks denote continuous functions of the variable \( z \). Hence, we have \( \lim_{t\to\theta}(t-\theta)\det(\tilde{\Psi}(z,t)) = -z\eta_2 + \eta_1 \). By [10] Theorem 6.2, \( -z\eta_2 + \eta_1 = -\tilde{\pi}^{-q}h(z)^{-1} \).

At once:

\[
-\tilde{\pi}^{-q}h(z)^{-1} = \lim_{t\to\theta}(t-\theta)\det(\tilde{\Psi}(z,t)) = \lambda(\theta)\tilde{\pi}^{-q}h(z)^{-1}\lim_{t\to\theta}(t-\theta)s_{\text{Car}}(t) = -\lambda(\theta)\tilde{\pi}^{-q}h(z)^{-1},
\]

which implies that \( \lambda = \lambda(\theta) = 1 \) (\( \theta \) is transcendental over \( \mathbb{F}_q \)). Our Lemma follows.

In the next section, we study the functions \( s_1, s_2 \) as functions \( \Omega \to \mathbb{T}_{<q} \).

2.1.2 The \( s_i \)'s as functions \( \Omega \to \mathbb{T}_{<q} \).

We observe, by the definitions of \( s_1, s_2 \), and by the fact, remarked in [19], that \( \alpha_i \) is a modular form of weight \( q^i - 1 \) and type 0 for all \( i \), and by [10], that for all \( \gamma = \left( \begin{array}{cc} a & b \\ c & d \end{array} \right) \in \Gamma \):

\[
s_2(\gamma(z), t) = \sum_{i=0}^{\infty} (cz+d)^{q^i-1} \alpha_i(z) \frac{\gamma \cdot (z)}{\gamma \cdot t} = (cz+d)^{-1} s_{\lambda_1,cz+d}(z) = (cz+d)^{-1}(\tilde{\gamma} s_1(z,t) + \tilde{\gamma} s_2(z,t)).
\]

Similarly,

\[
s_1(\gamma(z), t) = \sum_{i=0}^{\infty} (cz+d)^{q^i-1} \alpha_i(z)(\gamma(z))^{q^i} \frac{\gamma \cdot (z)}{\gamma \cdot t} = (cz+d)^{-1} s_{\lambda_1,az+b}(z) = (cz+d)^{-1}(\tilde{\gamma} s_1(z,t) + \tilde{\gamma} s_2(z,t)).
\]
Let us write
\[ \Sigma(z, t) := \begin{pmatrix} s_1(z, t) \\ s_2(z, t) \end{pmatrix}. \]

We have proved:

**Lemma 6** For all \( \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma \), and for all \( z \in \Omega \), we have the following identity of series in \( T_{<q} \):
\[ \Sigma(\gamma(z), t) = (cz + d)^{-1} \pi \cdot \Sigma(z, t), \]
where \( \pi \) is the matrix \( \begin{pmatrix} a & b \\ \pi & 1 \end{pmatrix} \in \Gamma \).

### 2.1.3 Behaviour of \( s_2 \) at the infinity cusp and \( u \)-expansion

We use the results of the previous subsections to see how the function \( s_2 \) behaves for \( z \) approaching the cusp at infinity of the rigid analytic space \( \Gamma \setminus \Omega \). Here we will prove two lemmas.

**Lemma 7** There exists a real number \( r > 0 \) such that for all \( (z, t) \in \Omega \times C \) with \( |u| = |u(z)| < r, |t| < r \), we have:
\[ s_2(z, t) = \tilde{\pi}^{-1} s_{\text{Car}}(t) + \sum_{m \geq 1} \kappa_m(t) u^m, \]
where for \( m \geq 1 \),
\[ \kappa_m(t) = \sum_{i \geq 1} \frac{c_{i, m}}{\theta^q - t} \]
\[ = \sum_{j \geq 0} t^j \sum_{i \geq 1} c_{i, m} \theta^{-q(1+j)} \in T_{<q}, \]
the \( c_{i, m} \)'s being the coefficients in the expansions (27).

**Proof.** For \( z \in \Omega \) such that \( |u| < B^{-1} \) with \( B \) as in (22), and for \( |t| < q \), (12) yields:
\[ s_2(z, t) = \frac{1}{\theta - t} + \sum_{i \geq 1} \frac{\alpha_i(z)}{\theta^q - t} \]
\[ = \frac{1}{\theta - t} + \sum_{i \geq 1} \sum_{m \geq 0} c_{i, m} u^m \frac{1}{\theta^q - t} \]
\[ = \frac{1}{\theta - t} + \sum_{i \geq 1} c_{i, 0} \frac{1}{\theta^q - t} + \sum_{m \geq 1} u^m \sum_{i \geq 1} c_{i, m} \frac{1}{\theta^q - t} \]
\[ = \tilde{\pi}^{-1} \sum_{i \geq 0} d_i \frac{1}{\theta^q - t} + \sum_{m \geq 1} \kappa_m(t) u^m \]
\[ = \tilde{\pi}^{-1} s_{\text{Car}}(t) + \sum_{m \geq 1} \kappa_m(t) u^m, \]
where, in the second equality we have substituted the \( u \)-expansions of the \( \alpha_i \)'s in our formulas, in the third we have separately considered constant terms, in the fourth equality, we have used (21), in the fifth we have recognised the shape of \( s_{\text{Car}} \) (15), and we have noticed, by using (22), that for all \( t \in C \) such that \( |t| \leq q, |\kappa_m(t)| \leq B^m q^{-1} \).
Later, we will need to do some arithmetic with the $u$-expansion \( \tilde{s_C}(t) \). To this purpose, it is advantageous to set:

$$d(z,t) := \tilde{s_C}(t)^{-1} s_2(z,t),$$

function for which (23) becomes:

$$d = (t - \theta q^q) d^{(2)} + g d^{(1)}.$$  \hspace{1cm} (28)

We will need part of the following lemma.

**Lemma 8** We have

$$d = \sum_{i \geq 0} c_i(t) u^{(q-1)i} \in 1 + u^{q-1} F_q[[t,\theta]][[u^{q-1}]].$$  \hspace{1cm} (29)

More precisely,

$$d = 1 + (\theta - t) u^{q(q-1)} + (\theta - t) u^{(q^2-q+1)(q-1)} + \cdots \in 1 + (t - \theta) u^{q-1} F_q[[t,\theta]][[u^{q-1}]],$$

where the dots $\cdots$ stand for terms of higher order in $u$.

Let $i$ be a positive integer. We have

$$-\infty \leq \deg_t c_i \leq \log_{q^2} i,$$

where $\log_{q^2}$ is the logarithm in base $q^2$, with the convention $\deg_t 0 = -\infty$.

**Proof.** For simplicity, we write $\nu = u^{q-1}$. It is clear, looking at Lemma 7, that $d$ is a series in $T_{<q^2}[[\nu]]$. We have the series expansions (cf. [11, Section 10]):

$$g = 1 - [1] \nu + \cdots = \sum_{n=0}^{\infty} \gamma_n \nu^n \in A[[\nu]],$$

$$\Delta = -\nu (1 - \nu^{q-1} + \cdots) = \sum_{n=0}^{\infty} \delta_n \nu^n \in u A[[\nu]],$$

We deduce, from (28), that

$$c_m = (t - \theta q^q) \sum_{i+q^2 j = m} \delta_i c_j^{(2)} + \sum_{i+q j = m} \gamma_i c_j^{(1)},$$  \hspace{1cm} (30)

which yields inductively that $c_i$ belongs to $F_q[[t,\theta]]$, because the coefficients of the $u$-expansions of $\Delta$ and $g$ are $A$-integral. The statement on the degrees of the coefficients of the $c_i$’s, is also a simple inductive consequence of (30) and the following two facts: that $\deg_t \delta_i, \deg_t \gamma_i \leq 0$, and that $\deg_t c_j^{(k)} = \deg_t c_i$ for all $i, k$ ($t$ is $\tau$-invariant).

The explicit formula for the coefficients $c_i$ with $i \leq q^2 - q + 1$ is an exercise that we leave to the reader, which needs [11 Corollaries (10.3), (10.11)]. The explicit computation can be pushed easily to coefficients of higher order, but we skip it as we will not need these explicit formulas at all in this paper. The fact that the coefficients $c_i$ belong to the ideal generated by $t - \theta$ for $i \geq 1$ follows from the computation of the residues in \[21.1.4\].
3 The function $E$

The function of the title is defined, for $z \in \Omega$ and $t \in B_q$, by:

$$E(z, t) = -\frac{d}{h(z)}d^{(1)}(z, t) = -(t - \theta)^{-1}d^{(2)}q h(z) s^{-1}_{\text{Car}}(t) s^{(1)}(z, t),$$

with $d$ the function of Lemma 8. This section is entirely devoted to the description of its main properties. Three Propositions will be proved here.

In Proposition 9 we use the arguments of 2.1.1 to show that, just as $d$, $E$ satisfies a linear $\tau$-difference equation of order 2 with coefficients isobaric in $C[[t]] [g, h]$ (5).

In Proposition 10, where we use this time the arguments developed in 2.1.2, we analyse the functional equations relating the values of $E$ at $z$ and $\gamma(z)$, where $\gamma = \left( \begin{array}{cc} a & b \\ c & d \end{array} \right) \in \Gamma$; they involve the factors of automorphy:

$$J_\gamma(z) = cz + d, \quad J_\gamma(\zeta) = \tau s_1(z, t) s_2(z, t) + \bar{d},$$

with values convergent in $C[[t]]$.

Proposition 11 follows from what we did in 2.1.3 and describes the third important feature of the function $E$; the existence of a $u$-expansion in $F_q[[t, \theta]]$.

For Drinfeld quasi-modular forms, the degree in $\theta$ of the $n$-th coefficient of the $u$-expansion grows pretty rapidly with $n$ in contrast of the classical framework. The function $E$ does not make exception to this principle. However, the degree in $t$ of the $n$-th coefficient grows slowly, and this property is used crucially in the proof of the multiplicity estimate. Another important property studied in this section is that $E(z, \theta)$ is a well defined function $\Omega \rightarrow C$ and is equal to Gekeler’s function $E$.

3.1 linear $\tau$-difference equations

**Proposition 9** For all $z \in \Omega$, the function $E(z, \cdot)$ can be developed as a series of $\mathbb{T}_q$. Moreover, The following linear $\tau$-difference equation holds in $\mathbb{T}_q$, for all $z \in \Omega$:

$$E^{(2)} = \frac{1}{t - \theta q^r} (\Delta E + g\theta E^{(1)}).$$

(31)

**Proof.** After having chosen a $(q - 1)$-th root of $-\theta$, let us write, following Anderson, Brownawell, and Papanikolas in [2, Section 3.1.2],

$$\Omega(t) := (-\theta)^{\frac{1}{q-1}} \prod_{n=1}^{\infty} \left( 1 - \frac{t}{\theta q^n} \right) \in (\mathbb{T}_\infty \cap K_{\infty}((-\theta)^{\frac{1}{q-1}})[[t]]) \setminus K_\infty(t)^{\text{alg}}.$$ 

It is plain that

$$\Omega^{(-1)}(t) = (t - \theta)\Omega(t).$$

Thanks to the remark on the $\overline{K}$-vector space structure of the set of solutions of (14) and after the computation of the constant of proportionality, we get

$$s_{\text{Car}}(t) = \frac{1}{\Omega^{(-1)}(t)}.$$

(32)

5 This phenomenon holds with more generality and should be compared with a result of Stiller in [22].

12
At once, we obtain that the function $s_{\text{Car}}$ has no zeros in the domain $C \setminus \{\theta, \theta^2, \ldots\}$ from which it follows that $((t - \theta)s_{\text{Car}})^{-1} \in T_{<q}$. Moreover, for all $z \in \Omega$, we have $s_2 \in T_{<q}$ so that $s_2^{(1)} \in T_{<q^r}$. Multiplying the factors that define the function $E$, we then get, for all $z \in \Omega$, that $E(z, \cdot) \in T_{<q^r}$, which gives the first part of the proposition (and in fact, it can be proved that $d(E(z, \cdot)) \in T_{\infty}$ for all $z \in \Omega$, but we skip on this property since it will not be needed in the present paper).

In order to prove the second part of the proposition, we remark, from (23) (or what is the same, (24)), that

$$s_2^{(3)} = \frac{t - \theta^q}{\Delta t} s_2^{(1)} - \frac{\gamma h}{\Delta t} s_2^{(2)}; \text{ or equivalently, } d^{(3)} = \frac{1}{(t - \theta^q)\Delta t}(d^{(1)} - g^q d^{(2)}).$$

By the definition of $E$ and the $\tau$-difference equation (13) we find the relation:

$$E^{(k)} = -(t - \theta^q)^{-1}(t - \theta^q - 1)^{-1} \cdots (t - \theta)^{-1} \pi^q \cdot \pi^q \cdots \pi^q s_{\text{Car}}^{(k+1)},$$

$$= -h^k d^{(k+1)} \quad (33)$$

for $k \geq 0$. Substituting the above expression for $d^{(3)}$ in it, we get what we expected. \hfill $\square$

### 3.2 Factors of automorphy, modularity

In the next proposition, the function $E$ is viewed as a function $\Omega \rightarrow T_{>0}$ (it can be proved that it defines, in fact, a function $\Omega \rightarrow T_{\infty}$). In order to state the proposition, we first need a preliminary discussion.

If $\omega \notin \theta \Lambda$, then $\epsilon_\Lambda(\omega/\theta) \neq 0$ and $s_\Lambda(\omega)(t) \in T_{>0}$ (group of units of $T_{>0}$), so that, for every $z$ fixed, $s_2(z, \cdot)^{-1} \in T_{>0}$ (6). Hence, we have a well defined map

$$\xi : \Omega \rightarrow T_{>0}^*, z \mapsto \frac{s_2(z, t)}{s_2(z, t)},$$

and we can consider the map

$$(\gamma, z) = \left(\begin{pmatrix} a & b \\ c & d \end{pmatrix}, z\right) \in \Gamma \times \Omega \mapsto J_\gamma(z) := \overline{c} \xi + \overline{d} \in T_{>0}.$$

Since $c, d$ are relatively prime, we have $cz + d \notin \theta \Lambda$, implying that $\pi s_2 + \overline{d} s_2 = s_\Lambda(cz + d) \in T_{>0}^\times$. Therefore, for all $\gamma \in \Gamma$ and $z \in \Omega$, $J_\gamma \in T_{>0}^\times$.

Moreover, by (23) we have, for all $\gamma \in \Gamma$ and $z \in \Omega$,

$$\xi(\gamma(z)) = \overline{c}(\xi(z)) \in C((t)),$$

so that, for $\gamma, \delta \in \Gamma$ and $z \in \Omega$,

$$J_{\gamma\delta}(z) = J_\gamma(\delta(z))J_\delta(z). \quad (35)$$

The map $J : \Gamma \times \Omega \rightarrow T_{>0}^\times$ is our “new” factor of automorphy, to be considered together with the more familiar factor of automorphy

$$J_\gamma(z) := cz + d.$$

The radius of convergence, in principle depending on $z$, seems difficult to compute.
Let us also write, for \( \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma \):

\[
L_\gamma(z) = \frac{c}{cz + d},
\]

\[
L_\gamma(z) = \frac{\gamma}{\gamma_s + d\gamma_t}.
\]

We remark that for all \( \gamma \in \Gamma \), \( L_\gamma(z) \) belongs to \( T_{>0} \) because \( s_2 J_\gamma(z) \in T_{>0}^\gamma \). Moreover, the functions \( J_\gamma \) and \((\theta - t)^{-1} L_\gamma \) are deformations of \( J_\gamma \) and \( L_\gamma \) respectively, for all \( \gamma \in \Gamma \). Indeed, we recall that \((t - \theta)s_2(z,t) \to -1 \) and \((t - \theta)s_1(z,t) \to -z \) as \( t \to \theta \). Hence, \( \lim_{t \to \theta} \gamma_s = z \).

This implies that

\[
\lim_{t \to \theta} J_\gamma(z) = J_\gamma(z).
\]

In a similar way we see that

\[
\lim_{t \to \theta} (t - \theta)^{-1} L_\gamma(z) = -L_\gamma(z).
\]

We further define the sequence of functions \( (g_k^\gamma)_{k \geq 0} \) by:

\[
g^\gamma_0 = 0, \quad g^\gamma_1 = 1, \quad g^\gamma_2 = g, \quad g^\gamma_k = (t - \theta g^\gamma_{k-1})g^\gamma_{k-2} \Delta^k - 2 g^\gamma_{k-1} q^\gamma_{k-1}, \quad k \geq 2,
\]

so that for all \( k \geq 0 \), we have the identity \( g^\gamma_k(z, \theta) = g_k(z) \), the function introduced in \([11, \text{Equation (6.8)}]\).

We have:

**Proposition 10** For all \( z \in \Omega \), \( \gamma \in \Gamma \) and \( k \geq 0 \) the following identity of formal series of \( T_{>0} \) holds:

\[
E(k)(\gamma(z), t) = \det(\gamma)^{-1} J_\gamma(z)^k J_\gamma(z) \times \left( E(k)(z, t) + \frac{g_k^\gamma(z)}{\pi(t - \theta)(t - \theta^q) \cdots (t - \theta^q)^{k-1}} L_\gamma(z) \right).
\]

**Proof.** From the deformation of Legendre's identity \([25]\) we deduce that

\[
s^{(1)}_1 = \frac{1}{s^2} (s^1 s^1_2 - \pi^{-1} q h^{-1} s_{\text{Car}}^2).
\]

Let \( \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma \). Applying \( \pi \) on both left and right hand sides of

\[
s_2(\gamma(z)) = J_\gamma^{-1} J_\gamma s_2(z) = J_\gamma^{-1} (\pi s_1(z) + \overline{\pi} s_2(z)),
\]

consequence of Lemma \([4]\) we see that

\[
s^{(1)}_2(\gamma(z)) = J_\gamma^{-q} (\overline{\pi} s^{(1)}_1 + \overline{\pi} s^{(1)}_2).\]

We now eliminate \( s^{(1)}_1 \) from this identity and \([39]\), getting identities in \( T_{>0} \). Indeed,

\[
\overline{\pi} s^{(1)}_1 + \overline{\pi} s^{(1)}_2 = \frac{\pi}{s^2} (s^1 s^1_2 - \pi^{-1} q h(z)^{-1} s_{\text{Car}}(t)) + \overline{\pi} s^{(1)}_2
\]

\[
= s^{(1)}_2 \left( \frac{\pi s^1}{s^2} + \overline{\pi} \right) - \pi^{-1} q h(z)^{-1} s_{\text{Car}}(t) s^{(1)}_2
\]

\[
= \left( \frac{\pi s^1}{s^2} + \overline{\pi} \right) \left( s^{(1)}_2 - \pi^{-1} q h(z)^{-1} s_{\text{Car}}(t) \frac{\pi}{\overline{\pi} s^1 + \overline{\pi} s^2} \right).
\]

14
that is,
\[ s_2^{(1)}(\gamma(z)) = J_\gamma^{-q} J_\gamma \left( s_2^{(1)}(z) - \frac{\bar{\pi}^{-1-q} s_{\text{Car}}(t)}{h(z)} L_\gamma \right). \]  
(41)

This functional equation is equivalent to the following functional equation for \( d^{(1)} \) (in \( T_{>0} \)):
\[ d^{(1)}(\gamma(z)) = J_\gamma^{-q} J_\gamma \left( d^{(1)}(z) - \frac{1}{\pi(t - \theta) h(z)} L_\gamma \right). \]  
(42)

This already implies, by the definition of \( E \) and the modularity of \( h \):
\[ E(\gamma(z)) = \det(\gamma)^{-1} J_\gamma J_\gamma \left( E(z) + \frac{1}{\pi(t - \theta)} L_\gamma \right) \]
which is our proposition for \( k = 0 \).

We point out that (26) implies the functional equation, for all \( \gamma \in \Gamma \):
\[ d(\gamma(z)) = J_\gamma^{-1} J_\gamma d(z). \]  
(43)

The joint application of (43), (40), (42) and (23) and induction on \( k \) imply, for all \( k \geq 0 \) and \( \gamma \in \Gamma \), the functional equation in \( T_{>0} \):
\[ d^{(k)}(\gamma(z)) = J_\gamma^{-q^k} J_\gamma \left( d^{(k)}(z) - \frac{g_{k-1}^*}{\pi h(z) \bar{\theta}^{k-1} (t - \theta)(t - \theta^q) \cdots (t - \theta^{q^{k-1}})} L_\gamma \right), \]  
(44)

where we have also used the functional equation (14). By (33), we end the proof of the proposition.

3.3 \( u \)-expansions

Proposition 11 We have
\[ E(z, t) = u \sum_{n \geq 0} c_n(t) u^{(q-1)n} \in u \mathbb{P}[\theta, t][[u^{q-1}]], \]
where the formal series on the right-hand side converges for all \( t, u \) with \( |t| \leq q \) and \( |u| \) small. The terms of order \( \leq q(q - 1) \) of the \( u \)-expansion of \( E \) are:
\[ E = u(1 + u^{(q-1)^2} - (t - \theta) u^{(q-1)q} + \cdots). \]  
(45)

Moreover, for all \( n > 0 \), we have the following inequality for the degree in \( t \) of \( c_n(t) \):
\[ \deg_t c_n \leq \log_q n, \]
where \( \log_q \) denotes the logarithm in base \( q \) and where we have adopted the convention \( \deg_t 0 = -\infty \).

Proof. This is a simple consequence of Lemma 8 and the definition of \( E \).

Remark 12 Let us introduce the function
\[ \mu = \bar{\pi}^{-1-q} s_2^{(1)} / s_2 \in C[[t, u^{q-1}]]. \]
By (23), \( \mu \) satisfies the non-linear \( \tau \)-difference equation:

\[
\mu^{(1)} = \frac{(t - \theta)}{\Delta} \mu^{-1} - \frac{g}{\Delta}.
\]

Hence, \( \mu = (t - \theta) \Delta^{-1} (\mu^{(1)} + g/\Delta)^{-1} \). Although not needed in this paper, we point out that this functional equation gives the following continued fraction development, which turns out to be convergent for the \( u \)-adic topology:

\[
\mu = \frac{(t - \theta)}{\Delta(t - \theta \delta)} + \frac{\Delta q(t - \theta \delta^2)}{g^q + \Delta q^2(t - \theta \delta^3) + \cdots} \in \mathbb{F}[t, \theta][[v]].
\]

This property should be compared with certain continued fraction developments in [15, Section 4, 5], or the continued fraction developments described after [14, Theorem 2].

### 4 Bi-weighted automorphic functions

In this section we introduce a class of bi-weighted automorphic functions that we call almost \( A \)-quasi-modular forms. We will see that they generate a \( \mathbb{T}_{>0} \)-algebra \( \tilde{\mathcal{M}} \) with natural embedding in \( C[[t, u]] \). Thanks to the two kinds of factor of automorphy described below, \( \tilde{\mathcal{M}} \) is also graded by the group \( G = \mathbb{Z}^2 \times \mathbb{Z} / (q - 1) \mathbb{Z} \). We will not pursue, in this paper, any investigation on the structure of \( \tilde{\mathcal{M}} \); this will be objective of another work.

We will show, with the help of the results of Section 3, that \( g, h, E, F \in \tilde{\mathcal{M}} \) with \( F = \tau E \). It will be proved that for this graduation, the degrees (in \( \mathbb{Z}^2 \times \mathbb{Z} / (q - 1) \mathbb{Z} \)) of these functions are respectively the following elements of \( G \): \((q - 1, 0, 0), (q + 1, 1, 0), (1, 1, 1) \) and \((q, 1, 1) \) and we will show from this that they are algebraically independent over \( C((t)) \) (also \( E \) belongs to \( \tilde{\mathcal{M}} \), but we will not use this property). Since they take values in \( \mathbb{T}_{<q^2} \), we will study with some detail the four dimensional \( \mathbb{T}_{<q^2} \)-algebra \( \mathcal{M}^\dagger := \mathbb{T}_{<q^2}[g, h, E, F] \).

Proposition 9 implies that \( \tau \) acts on \( \mathcal{M}^\dagger \): If \( f \in \mathcal{M}^\dagger \) is homogeneous of degree \( (\mu, \nu, m) \) then \( \tau f \) is also homogeneous of degree \( (q\mu, \nu, m) \).

We will see that if \( f \in \mathcal{M}^\dagger \) is homogeneous of degree \( (\mu, \nu, m) \), the function

\[
\varepsilon(f) : z \mapsto f(z)|_{t=\theta}
\]

is a well defined Drinfeld quasi-modular form of weight \( \mu + \nu \), type \( m \) and depth \( \leq \nu \). An example is given by Lemma 15:

\[
\varepsilon(E) = E.
\]

#### 4.1 Preliminaries on the functions \( J_\gamma \) and \( L_\gamma \)

Let us consider three matrices in \( \Gamma \):

\[
\mathcal{A} = \begin{pmatrix} a & b \\ c & d \end{pmatrix}, \quad \mathcal{B} = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}, \quad \mathcal{C} = \mathcal{A} \cdot \mathcal{B} = \begin{pmatrix} * & * \\ x & y \end{pmatrix} \in \Gamma.
\]
Lemma 13 We have the following identities in $T > 0$:

\[ L_A(B(z)) = \det(B)^{-1}J_B(z)^2(L_C(z) - L_B(z)), \]
\[ L_A(\mathcal{B}(z)) = \det(B)^{-1}J_B(z)J_B(z)(L_C(z) - L_B(z)). \]

Proof. We begin by proving the first formula, observing that $c = \det(B)^{-1}(x\delta - y\gamma)$:

\[ J_B(z)^2(L_C(z) - L_B(z)) = \]
\[ = (\gamma z + \delta)^2 \left( \frac{x}{xz + y} - \frac{\gamma}{\gamma z + \delta} \right) \]
\[ = \det(B) \frac{c(\delta + \gamma z)}{(c\alpha + d\gamma)z + (c\beta + d\gamma)} \]
\[ = \det(B) \frac{c}{\frac{c\alpha + d\gamma}{c\beta + d\gamma}} \]
\[ = \det(B) \frac{c}{c\alpha z + \beta \gamma z + \delta + d} \]
\[ = \det(B) L_A(B(z)). \]

As for the second formula, we set \( \tilde{L}_A = \frac{c}{c\alpha z + \beta \gamma z + \delta + d} \),

where we recall that $\xi = \frac{s_1}{s_2}$. By using (34) and the obvious identity $\det(B) = \det(\mathcal{B})$, we compute in a similar way:

\[ J_B(z)^2(\tilde{L}_C(z) - \tilde{L}_B(z)) = \]
\[ = (\gamma z + \delta)^2 \left( \frac{\xi}{\xi z + \gamma} - \frac{\xi}{\xi z + \delta} \right) \]
\[ = \det(B) \frac{\xi}{\xi z + \gamma + \xi} \]
\[ = \det(B) \frac{\xi}{\xi z + \gamma + \xi + d} \]
\[ = \det(B) L_A(B(z)). \]

Hence, \( \tilde{L}_A(B(z)) = \det(B)^{-1}J_B(z)^2(\tilde{L}_C(z) - \tilde{L}_B(z)). \)

But \( \tilde{L}_A(z) = s_2(z)L_A(z), \)

so that

\[ \tilde{L}_A(B(z)) = s_2(B(z))L_A(B(z)) \]
\[ = (\gamma s_1(z) + \delta s_2(z))L_A(B(z)) \]
\[ = s_2(z)J_B(z)^{-1}J_B(z)L_A(B(z)), \]

where $s_1, s_2$ are considered as functions $\Omega \rightarrow T > 0$, from which we deduce the expected identity. \( \square \)
4.2 Almost $A$-quasi-modular forms.

We recall that for all $z \in \Omega$ and $\gamma \in \Gamma$, we have $J_\gamma, J_{\gamma^*}, L_\gamma, L_{\gamma^*} \in \mathbb{T}_{>0}$.

Let $r$ be a positive real number and $f : \Omega \to \mathbb{T}_{<r}$ a map. We will say that $f$ is regular if the following properties hold.

1. There exists $\varepsilon > 0$ such that, for all $t_0 \in \mathbb{C}$, $|t_0| < \varepsilon$, the map $z \mapsto f(z, t_0)$ is holomorphic on $\Omega$.

2. For all $a \in A$, $f(z + a) = f(z)$. Moreover, there exists $c > 0$ such that for all $z \in \Omega$ with $|u(z)| < c$ and $t$ with $|t| < c$, there is a convergent expansion

$$f(z, t) = \sum_{n,m \geq 0} c_{n,m} t^n u^m,$$

where $c_{n,m} \in \mathbb{C}$.

Definition 14 (Almost $A$-quasi-modular forms) Let $f$ be a regular function $\Omega \to \mathbb{T}_{<r}$, for $r$ a positive real number. We say that $f$ is an almost-$A$-quasi-modular form of weight $(\mu, \nu)$, type $m$ and depth $\leq l$ if there exist regular functions $f_{i,j} : \Omega \to \mathbb{T}_{<r}$, $0 \leq i + j \leq l$, such that for all $\gamma \in \Gamma$ and $z \in \Omega$ the following functional equation holds in $\mathbb{T}_{>0}$:

$$f(\gamma(z), t) = \det(\gamma)^{-m} J_\gamma^{-1} J_{\gamma^*}^{l} \left( \sum_{i+j \leq l} f_{i,j} L_\gamma^{i} L_{\gamma^*}^{j} \right).$$

(48)

The radius of convergence $\rho(f)$ of an almost $A$-quasi-modular form $f : \Omega \to \mathbb{T}_{>0}$ is the supremum of the set of the real numbers $r$ such that the maps $f, f_{i,j}$ appearing in (48) simultaneously are well defined maps $\Omega \to \mathbb{T}_{<r}$.

We will say that $\mu = \mu(f), \nu = \nu(f), m = m(f)$ are respectively the first weight, the second weight and the type of $f$.

4.2.1 Some remarks.

It is obvious that in (48), $f = f_{0,0}$ (use $\gamma = \text{identity matrix}$).

If $\lambda \in \mathbb{T}_{>0}$, then the map $z \mapsto \lambda$ trivially is an almost $A$-quasi-modular form of weight $(0,0)$, type $0$, depth $\leq 0$. The radius $\rho(\lambda)$ is then just the radius of convergence of the series $\lambda$.

Examples of almost $A$-quasi-modular forms are Drinfeld quasi-modular forms. To any Drinfeld quasi-modular form of weight $w$, type $m$, depth $\leq l$ is associated an almost $A$-quasi-modular form of weight $(w,0)$, type $m$, depth $\leq l$ whose radius is infinite.

The $\mathbb{T}_{>0}$-algebra $\mathbb{T}_{>0}[g, h]$ is graded by the couples $(w,m) \in \mathbb{Z} \times \mathbb{Z}/(q-1)\mathbb{Z}$ of weights and types, and the isobaric elements are all almost $A$-quasi-modular forms with the second weight $0$.

The function $s_2$ is, by Lemmas 3 and 4, an almost $A$-quasi-modular form of weight $(-1,1)$, depth $0$, type $0$. The radius is $q$, by the results of Section 2.3.

If $f$ is an almost $A$-quasi-modular form of weight $(\mu, \nu)$, type $m$, depth $\leq l$ and radius of convergence $> q$, then $\varepsilon(f) := f|_{t=0}$ is a well defined holomorphic function $\Omega \to \mathbb{C}$. It results from (36) and (37) that $\varepsilon(f)$ is a Drinfeld quasi-modular form of weight $\mu + \nu$, type $m$ and depth $\leq l$.

The function $f := s_2$ is not well defined at $t = \theta$ because its radius of convergence is $q$, and we know from (27) that there is divergence at $\theta$. However, the function $f := (t - \theta)s_2$, which is an almost $A$-quasi-modular of same weight, type and depth as $s_2$, has convergence radius $q^3$.

Therefore, $\varepsilon(f)$ is well defined, and is the constant function $-1$ by the results of Subsection 2.1.1.
From (41) we see that the function $s_{1}^{(2)}$ is not an almost $A$-quasi-modular form. The non-zero function $\varepsilon(s_{1}^{(2)})$ is well defined and we have already mentioned the results of Gekeler in [10] that allow to compute it.

Let us write $\phi = \varepsilon(E)$, which corresponds to a well defined series of $uC[[u^{q-1}]]$ by (45). We obtain, by using (38), (36) and (37) with $k = 0$, that

$$\phi(\gamma(z)) = \det(\gamma)^{-1}(cz + d)^{2}\left(\phi(z) - \frac{\pi^{-1}}{cz + d}\right).$$

This is the collection of functional equations of the Drinfeld quasi-modular form $E(2)$, whose $u$-expansion begins with the term $u$. Applying [3, Theorem 1] we obtain:

**Lemma 15** We have, for all $z \in \Omega$:

$$\varepsilon(E) = E(z, \theta) = E(z).$$

It is easy to verify, as a confirmation of this result, that the first coefficients of the $u$-expansion of $E$ given in (45) agree, substituting $t$ by $\theta$, with the $u$-expansion of $E$ that we know already after [11, Corollary (10.5)]:

$$E = u(1 + v(q - 1) + \cdots).$$

More generally, Propositions [9, 10] and [11] imply that for all $k \geq 0$, $E^{(k)}$ is an almost $A$-quasi-modular form of weight $(q^{k}, 1)$ type 1 and depth $\leq 1$ with convergence radius $\geq q^{q}$, so that $\varepsilon(E^{(k)})$ is well defined, and is a Drinfeld quasi-modular form of weight $q^{k} + 1$, type 1 and depth $\leq 1$.

### 4.2.2 Grading by the weights, filtering by the depths.

For $\mu, \nu \in \mathbb{Z}$, $m \in \mathbb{Z}/(q - 1)\mathbb{Z}$, $l \in \mathbb{Z}_{\geq 0}$, we denote by $\widetilde{M}_{\mu, \nu, m}^{\leq l}$ the $\mathbb{T}_{>0}$-module of almost $A$-quasi-modular forms of weight $(\mu, \nu)$, type $m$ and depth $\leq l$. We have

$$\widetilde{M}_{\mu, \nu, m}^{\leq l} \subset \widetilde{M}_{\mu, \nu, m}^{\leq l + t'} \subset \widetilde{M}_{\mu, \nu, m + m'}^{\leq l + t}. $$

We also denote by $\widetilde{M}$ the $\mathbb{T}_{>0}$-algebra generated by all the almost $A$-quasi-modular forms. We prove below that this algebra is graded by the group $G = \mathbb{Z}^{2} \times \mathbb{Z}/(q - 1)\mathbb{Z}$, filtered by the depths (Proposition 20), and contains five algebraically independent functions $E, g, h, E, F$ (Proposition 21).

Let $K$ be any field extension of $\mathbb{F}_{q}(t, \theta)$. The key result of this section is the following elementary lemma.

**Lemma 16** The subset $\Theta = \{(d, \bar{d}), d \in A\} \subset \mathbb{A}^{2}(K)$ is Zariski dense.

**Proof.** Let us assume by contradiction that the lemma is false and let $\overline{\Theta}$ be the Zariski closure of $\Theta$. Then, we can write

$$\overline{\Theta} = \bigcup_{i \in \mathcal{I}} \Theta_{i} \cup \bigcup_{j \in \mathcal{J}} \tilde{\Theta}_{j},$$

where the $\Theta_{i}$’s are irreducible closed subsets of $\mathbb{A}^{2}(K)$ of dimension 1, the $\tilde{\Theta}_{j}$’s are isolated points of $\mathbb{A}^{2}(K)$, and $\mathcal{I}, \mathcal{J}$ are finite sets.

From $\Theta = \Theta + (d, \bar{d})$ for all $d \in A$ we deduce $\overline{\Theta} = \overline{\Theta} + (d, \bar{d})$. The translations of $\mathbb{A}^{2}(K)$ by points such as $(d, \bar{d})$ being bijective, they induce permutations of the sets $\{\Theta_{i}\}$ and $\{\tilde{\Theta}_{j}\}$.

19
which we easily deduce that \( J = \emptyset \). Therefore, the ideal of polynomials \( R \in \mathcal{K}[X, Y] \) such that \( R(\Theta) \subset \{0\} \) is principal, generated by a non-zero polynomial \( P \).

Now, if \( b \in A, m_b(\Theta) \subset \Theta \), where \( m_b(x, y) := (bx, by) \). Hence, \( P(m_b(X, Y)) \in (P) \) and there exists \( \kappa_b \in \mathcal{K}^\times \) such that \( P(bX, bY) = \kappa_bP(X, Y) \).

Let us write:
\[
P(X, Y) = \sum_{\alpha, \beta} c_{\alpha, \beta}X^\alpha Y^\beta,
\]
and choose \( b \not\in \mathbb{F}_q \). If \( c_{\alpha, \beta} \neq 0 \), then \( \kappa_b = b^{-\alpha}b^{-\beta} \). If \( P \) is not a monomial, we have, for \( (\alpha, \beta) \neq (\alpha', \beta') \), \( c_{\alpha, \beta}, c_{\alpha', \beta'} \neq 0 \), so that \( b^{-\alpha}b^{-\beta} = b^{-\alpha'}b^{-\beta'} \), yielding a contradiction, because \( b \not\in \mathbb{F}_q \).

If \( P \) is a monomial, however, it cannot vanish at \((1, 1) \in \Theta\); contradiction.

**Lemma 17** Let us suppose that for elements \( \psi_{\alpha, \beta} \in C((t)) \) and for a certain element \( z \in \Omega \) we have an identity:
\[
\sum_{\alpha, \beta} \psi_{\alpha, \beta} J_\gamma^\alpha J_\gamma^\beta = 0, \tag{49}
\]
in \( C((t)) \), for all \( \gamma = \begin{pmatrix} a & b \\ 1 & d \end{pmatrix} \in \Gamma \) with determinant 1, the sum being finite. Then, \( \psi_{\alpha, \beta} = 0 \) for all \( \alpha, \beta \).

**Proof.** Let us suppose by contradiction the existence of a non-trivial relation (49). We have, with the hypothesis on \( \gamma \), \( J_\gamma = z + d, J_\gamma = \xi + d \in C((t)) \), so that the relation of the lemma implies the existence of a relation:
\[
\sum_{\alpha, \beta} \ell_{\alpha, \beta} d^\alpha d^\beta = 0, \quad d \in A,
\]
with \( \ell_{\alpha, \beta} \in \mathcal{K} = C((t)) \) not all zero, and all, but finitely many, vanishing. Lemma 16 yields a contradiction. \( \square \)

Another useful lemma is the following. The proof is again a simple application of Lemma 16 and will be left to the reader.

**Lemma 18** If the finite collection of functions \( f_{i,j} : \Omega \to \mathbb{T}_{>0} \) is such that for all \( z \in \Omega \) and for all \( \gamma \in \Gamma \),
\[
\sum_{i,j} f_{i,j}(z)L_\gamma^i L_j^\gamma = 0,
\]
then the functions \( f_{i,j} \) are all identically zero.

**Lemma 19** Let \( f \) be an almost \( A \)-quasi-modular form of type \( m \) with \( 0 \leq m < q - 1 \). Then, with \( v = u^{q-1} \),
\[
f(z) = u^m \sum_{i \geq 0} c_i(t) v^i.
\]
for all \( z \) \( f \) for certain functions

Recalling Definition 14 (identity (48)), we have, for all \( i \)

Proof. We begin by proving the property concerning the grading by the group \( \mathbb{G} \). Let us consider distinct triples \( (\mu_1, \nu_1, m_1) \in \mathbb{Z}^2 \times \mathbb{Z}/(q - 1)\mathbb{Z} \). Let us consider distinct triples \( (\mu_1, \nu_1, m_1) \in \mathbb{Z}^2 \times \mathbb{Z}/(q - 1)\mathbb{Z} \), \( i = 1, \ldots, s \), non-negative integers \( l_1, \ldots, l_s \) and non-zero elements \( f_i \in \mathcal{M}_{\mu_i, \nu_i, m_i} \). Then, we claim that \( \sum_{i=1}^{s} f_i \neq 0 \). To see this, we assume by contradiction that for some forms \( f_i \) as in the proposition, we have the identity in \( \mathbb{T}_{>0} \):

\[
\sum_{i=1}^{s} f_i = 0.
\]

Recalling Definition 14 (identity (48)), we have, for all \( i = 1, \ldots, s \), \( \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma \), \( z \in \Omega \):

\[
f_i(\gamma(z), t) = \det(\gamma)^{-m_i}J^i_\gamma \prod_{j+k \leq l} f_{i,j,k}(z, t)L^j_\gamma L^k_\gamma,
\]

for certain functions \( f_{i,j,k} : \Omega \to \mathbb{T}_{>0} \).

Let us suppose first that \( \gamma \) is of the form \( \begin{pmatrix} a & b \\ 1 & d \end{pmatrix} \) with \( ad - b = 1 \). We recall that \( s_2(z)^{-1} \in \mathbb{T}_{>0} \) for all \( z \). Therefore, for all \( z \in \Omega \), \( s_2(z)^{-1} \) becomes the identity of formal series in \( \mathbb{T}_{>0} \):

\[
\sum_{i=1}^{s} \sum_{j+k \leq l} f_{i,j,k} s_2^{-k}(z + d)^{\nu_i - j}(\xi + d)^{\mu_i - k} = 0.
\]

(51)

By Lemma 17, (51) is equivalent to the relations:

\[
\sum_{i,j,k} \phi_{i,j,k} = 0, \quad \text{for all } \alpha, \beta \in \mathbb{Z}^2
\]

(52)

where \( \phi_{i,j,k} := f_{i,j,k} s_2^{-k} \) and the sum runs over the triples \((i, j, k)\) with \( i \in \{1, \ldots, s\} \) and \( j, k \) such that \( \mu_i - j = \alpha \) and \( \nu_i - k = \beta \), with obvious vanishing conventions on some of the \( \phi_{i,j,k}'s \).

Let \( \mu \) be the maximum value of the \( \mu_i \)'s, and let us look at the relations (52) for \( \alpha = \mu \). Since for all \( \mu_i < \mu \) we get \( \alpha = \mu > \mu_i - j \) for all \( j \geq 0 \), for such a choice of \( \alpha \) we get:

\[
\sum_{i,j,k} \phi_{i,0,k} = 0, \quad \text{for all } \beta \in \mathbb{Z}.
\]

(53)

where the sum is over the couples \((i, j)\) with \( i \) such that \( \mu_i = \mu \) and \( \nu_i - k = \beta \). Now, let \( \mathcal{E} \) be the set of indices \( i \) such that \( \mu_i = \mu \) and write \( \nu \) for the maximum of the \( \nu_i \) with \( i \in \mathcal{E} \). If \( j \) is such that \( \mu_j = \mu \), and if \( \nu \neq \nu_j \), then for all \( k \geq 0 \), \( \nu > \nu_j - k \), so that for \( \beta = \nu \), (53) becomes

\[
\sum_{i,j,k} \phi_{i,0,k} = 0.
\]

(54)

21
where the sum runs this time over the $i$’s such that $(\mu_i, \nu_i) = (\mu, \nu)$. But $\phi_{i,0,0} = f_{i,0,0} = f_i$ for $i = 1, \ldots, s$. Since the types of the $f_i$’s with same weights are distinct by hypothesis, Lemma 19 implies that for all $i$ such that $(\mu_i, \nu_i) = (\mu, \nu)$, $f_i = 0$. This contradicts our initial assumptions and proves our initial claim. Combining with Lemma 18, we end the proof of the proposition.

**Proposition 21** The functions

$$E, g, h, s_2, s_2^{(1)} : \Omega \to T_{>0}$$

are algebraically independent over the fraction field of $T_{>0}$.

**Proof.** Assume by contradiction that the statement of the proposition is false. Since $E, g, h, s_2, s_2^{(1)} \in \mathcal{M}$ are almost $A$-quasi-modular forms, by Proposition 20 there exist $(\mu, \nu), m \in \mathbb{Z}$, and a non-trivial relation (where the sum is finite):

$$\sum_{i,j \geq 0} P_{i,j} E^{s_2^{(1)}j} = 0,$$

with $P_{i,j} \in T_{>0}[g, h, s_2] \cap \mathcal{M}_{\mu, \nu, m-1}$ (for some $l \geq 0$). By Proposition 20, any vector space of almost $A$-quasi-modular forms of given weight and depth is filtered by the depths. Comparing with the functional equations (41) and [3, Functional equation (11)], and applying Lemma 18, we see that all the forms $P_{i,j}$ vanish. There are three integers $\alpha, m, n$ and a non-trivial polynomial relation $P$ among $g, h, s_2^{(1)}$ with coefficients in $T_{>0}$:

$$n \sum_{s=0}^{\infty} Q_s s_2^s = 0,$$

where $Q_s \in T_{>0}[g, h] \cap \mathcal{M}_{\mu, \nu, m-1}$ and for some $s, Q_s$ is non-zero. Since $\nu(Q_s) = 0$ for all $s$ such that $Q_s \neq 0$ and $\nu(s_2) = 1$, The polynomial $P$, evaluated at the functions $E, g, h, s_2, s_2^{(1)}$ is equal to $Qs_2^s$ for $Q \in T_{>0}[g, h] \setminus \{0\}$ and $s \in \mathbb{Z}$, quantity that cannot vanish because $g, h$ are algebraically independent over $T_{<q}$: contradiction.

5 Estimating the multiplicity

We prove Theorem 1 in this section.

5.1 Preliminaries

Let us denote by $\mathcal{M}^\dagger$ the $T_{<q}$-algebra $T_{<q}[g, h, E, F]$, where $F := E^{(1)}$; its dimension is 4, according to Proposition 21 and Proposition 10. By Proposition 20 this algebra is graded by the group $\mathbb{Z}^2 \times \mathbb{Z}/(q - 1)\mathbb{Z}$:

$$\mathcal{M}^\dagger = \bigoplus_{(\mu, \nu), m} \mathcal{M}^\dagger_{\mu, \nu, m},$$

where $\mathcal{M}^\dagger_{\mu, \nu, m} = \mathcal{M}_{\mu, \nu, m} \cap \mathcal{M}^\dagger$.

The operator $\tau$ acts on $\mathcal{M}^\dagger$ by Proposition 9. More precisely, we have the homomorphism of $\mathbb{F}_q[t]$-modules

$$\tau : \mathcal{M}^\dagger_{\mu, \nu, m} \to \mathcal{M}^\dagger_{\mu, \nu, m}.$$

Let us write $h = \pi h s_{\text{Car}}^{-1} s_2 = hd$. 22
Lemma 22  The formula $h = (t - \theta^q) F - g E$ holds, so that $h \in M_{q,1,1}^\dagger$ and $M^\dagger = T_{<q^q}[g, h, E, h]$.

Proof. From the definition of $E$ and (28), we find:

$$(t - \theta^q) F - g E =$$

$$= - (t - \theta^q) h \delta^2 + gh d^{(1)}$$

$$= (h)^q (-h^{q-1})^{-1} (d - gd^{(1)}) + gh d^{(1)}$$

$$= h d = h.$$  

This makes it clear that $h$ belongs to $M_{q,1,1}^\dagger$ and that $M^\dagger = T_{<q^q}[g, h, E, h]$.

We denote by $\varepsilon_{\mu,\nu,m}$ or again $\varepsilon$ the map which sends an almost $A$-quasi-modular form $f$ of weight $(\mu, \nu)$, type $m$, with radius $> q$ to the Drinfeld quasi-modular form $\varepsilon(f)$ of weight $\mu + \nu$, type $m$. This map is clearly a $C$-algebra homomorphism.

Lemma 23  We have $\varepsilon(h) = h$.

Proof. This follows from the limit $\lim_{t \to \theta} s_{\text{Car}}^{-1} s_2 = T\pi^{-1}$ and the definition of $d$.  

More generally, we have the following result.

Proposition 24  For all $(\mu, \nu, m)$, the map

$$\varepsilon : M^\dagger_{\mu,\nu,m} \to \overline{M}^\leq_{\mu+\nu,m}$$

is well defined and the inverse image of $0$ is the $T_{<q^q}$-module $(t - \theta) M^\dagger_{\mu,\nu,m}$.

Proof. Let $f$ be an element of $M^\dagger_{\mu,\nu,m}$. Then, by Lemma 22

$$f = \sum_{i=0}^{\nu} \phi_i h^{\nu-i} E^i,$$

where $\phi_i \in M_{\mu-i + (q-1)m-\nu} \otimes C T_{<q^q}$. Since $\lim_{t \to \theta} s_{\text{Car}}^{-1} s_2 = T\pi^{-1}$, we have $\varepsilon(h) = h$ by Lemma 23. Moreover, by Lemma 15, $\varepsilon(E) = E$, and

$$\varepsilon(f) = \sum_{i=0}^{\nu} \varepsilon(\phi_i) h^{\nu-i} E^i,$$

so that $\varepsilon(f) = 0$ if and only if $\varepsilon(\phi_i) = 0$ for all $i$. But for all $i$, $\phi_i$ is a polynomial in $g, h$ with coefficients in $T_{<q^q}$. If $\varepsilon(\phi_i) = 0$, then $\phi_i$ is a linear combination $\sum_{a,b} c_{a,b} g^a h^b$ with $c_{a,b} \in T_{<q^q}$ such that $c_{a,b}(\theta) = 0$. Since $T_{<q^q} \subset T$, it is a principal ideal domain and the last condition is equivalent to $\phi_i \in (t - \theta) (M \otimes C T_{<q^q})$. Hence, $\varepsilon(f) = 0$ if and only if, for all $i$, $\phi_i \in (t - \theta) (M \otimes C T_{<q^q})$. The proposition follows.

5.2 Multiplicity estimate in $M^\dagger$

By Proposition 11, $E = u + \cdots \in u F_q[t, \theta][[u^{q-1}]]$. Hence,

$$E^{(k)} = u^k + \cdots \in u^k F_q[t, \theta][[u^{(q-1)k}]], \quad k \geq 0,$$
Lemma 25  If algebra M follows:

\[
\nu \quad \text{and} \quad \lambda
\]

Let \( \frac{\nu}{\lambda} \) be the functions

\[
\mu, \nu, \mu, \lambda
\]

Proof. It is not difficult to show that the statement of this proposition cannot be improved (this can be checked with the functions \( E(k) \) in mind).

The computation of the weight and type of \( \phi_0 \) is obvious, knowing that \( \mu(h) = q \).

\[\phi := \text{Res}_E(f, f') = h^{\nu' + \nu' - \nu'} \phi_0,\]

where \( \phi_0 \in M_{w^*, m^*}(K) \), with

\[
w^* = \mu l + \mu l' - \nu l - q(\nu l' + \nu l - \nu l'), \quad m^* := ml + ml' - (\nu l' + \nu l').\]

Proof. With an application of an obvious variant of [20, Lemme 6.1] (7) we see that

\[
\phi \in M_{\mu l + \nu l'/\nu' l' - \nu l', m l + m l' - \nu l}(K).
\]

At the same time, \( \phi \in K[\nu, h, h'] \). Since \( \nu(g) = \nu(h) = 0 \) and \( \nu(h) = 1 \), we have \( \phi_0 := \phi / h^{\nu l' + \nu l'} \in M(K) \). The computation of the weight and type of \( \phi_0 \) is obvious, knowing that \( \mu(h) = q \).

\[\phi := \text{Res}_E(f, f') = h^{\nu' + \nu' - \nu'} \phi_0,\]

where \( \phi_0 \in M_{w^*, m^*}(K) \), with

\[
w^* = \mu l + \mu l' - \nu l - q(\nu l' + \nu l - \nu l'), \quad m^* := ml + ml' - (\nu l' + \nu l').\]

Proof. With an application of an obvious variant of [20, Lemme 6.1] (7) we see that

\[
\phi \in M_{\mu l + \nu l'/\nu' l' - \nu l', m l + m l' - \nu l}(K).
\]

At the same time, \( \phi \in K[\nu, h, h'] \). Since \( \nu(g) = \nu(h) = 0 \) and \( \nu(h) = 1 \), we have \( \phi_0 := \phi / h^{\nu l' + \nu l'} \in M(K) \). The computation of the weight and type of \( \phi_0 \) is obvious, knowing that \( \mu(h) = q \).
Proof of Proposition 26. Let $f$ be in $\mathbb{M}_{\nu,1,0}(\mathbb{K})$, with $\nu > 0$. Assume first that $f$, as a polynomial in $g,h,E,h$, is irreducible. If $f$ belongs to $\mathbb{K}[g,h]$ then $f = \phi h^\nu$ with $\phi \in M_{\mu - q\nu,0,0}(\mathbb{K})$ and

$$
\nu_\infty(f) \leq \nu_\infty(\phi) + \nu_\infty(h) \\
\leq \frac{\mu - q\nu}{q + 1} + \nu \\
\leq \frac{\mu + \nu}{q + 1} \\
\leq \nu\mu.
$$

We now suppose that $f \notin \mathbb{K}[g,h]$; there are two cases left.

Case (i). We suppose that $f$ divides $f^{(1)} \in \mathbb{M}_{\gamma q,1,0}(\mathbb{K})$ as a polynomial in $g,h,E,h$. For weight reasons, $f^{(1)} = af$ with $a \in M_{\mu(q - 1),0,0}(\mathbb{K})$ and $a \neq 0$. We also have $\nu_\infty(f^{(1)}) = q\nu_\infty(f)$ by (55). So that, by Lemma 25, $(q - 1)\nu_\infty(f) = \nu_\infty(a) \leq (q - 1)(q + 1)^{-1}\mu$. Hence, in this case, we get the stronger inequality (8)

$$
\nu_\infty(f) \leq \frac{\mu}{q + 1}.
$$

Case (ii). In this case, $f$ and $f^{(1)}$ are relatively prime. Since $f$ is irreducible, $\deg E(f) = l = \nu > 0$, so that $f,f^{(1)}$ depend on $E$, and their resultant $\phi$ with respect to $E$ is non-zero. We apply Lemma 27 with $f = f^{(1)}$, finding

$$
\phi = h^{\nu^2}\phi_0,
$$

with $\phi_0 \in M_{(q - 1)\nu(q - 1),0,0}(\mathbb{K})$, for a certain $m^*$ that can be computed with Lemma 27. By Lemma 25 again, $\nu_\infty(\phi_0) \leq \nu(\mu - \nu)$. Since $\nu_\infty(h) = 1$, $\nu_\infty(\phi) \leq \nu(\mu - \nu) + \nu^2 = \mu\nu$. Now, the number $\nu_\infty(\phi)$ is an upper bound for $\nu_\infty(f)$ by Bézout identity for the resultant.

We have proved the proposition if $f \in \mathbb{M}_{\mu,\nu,0}(\mathbb{K})$ is irreducible. If $f$ is not irreducible, we can write $f = \prod_{i=0}^n f_i$ with $f_i \in \mathbb{M}_{\mu,\nu_i,0}(\mathbb{K})$, $f_i \in \mathbb{M}_{\mu,\nu_i,0}(\mathbb{K})$ irreducible for all $i > 0$ with $\nu_i > 0$, and $\sum_i \mu_i = \mu$, $\sum_i \nu_i = \nu$, $\sum_i m_i \equiv m \mod (q - 1)$. Since $\nu_\infty(f) = \sum_i \nu_\infty(f_i)$, we get, applying Lemma 27,

$$
\nu_\infty(f) \leq \frac{\mu_0}{q + 1} + \sum_{i>0} \mu_i \nu_i \leq \mu\nu.
$$

$\square$

5.3 Reduced forms

Let $f$ be in $\mathbb{M}$. Since $\varepsilon(f) \in \mathbb{M} \subset C[[u]]$, it is legitimate to compare the quantities $\nu_\infty(f)$ and $\nu_\infty(\varepsilon(f))$. We have the inequality:

$$
\nu_\infty(f) \leq \nu_\infty(\varepsilon(f)),
$$

but the equality is not guaranteed in general, because the leading term of the $u$-expansion of $f$ can vanish at $t = \theta$.

$^8$It can be proved that $f$ is, in this case, a modular form multiplied by an element of $\mathbb{K}$, but we do not need this information here.
Definition 28 A function $f$ in $\mathbb{M}_\mu^{\uparrow}$ is reduced if $\nu_\infty(f) = \nu_{\infty}(\varepsilon(f))$, that is, if the leading coefficient of the $u$-expansion of $f$ does not vanish at $t = \theta$.

The next lemma provides a tool to construct reduced almost $A$-quasi-modular forms, useful in the sequel.

Lemma 29 Let $f \in \mathbb{M}_{\mu,\nu,m}^{\uparrow}$ be such that $f = \sum_{n \geq n_0} b_n u^n$, with $b_n \in \mathbb{F}_q[t,\theta]$ for all $n$ and $b_{n_0} \neq 0$. Then, for all $k > \log_q(\deg_t b_{n_0})$, the function $f^{(k)}$ is reduced.

Proof. We have $b_n^{(k)}(\theta) = b_{n_0}(\theta^{q^{-k}})u^k = 0$ if and only if $t - \theta^{1/q^k}$ divides the polynomial $b_{n_0}(t)$ in $K^{\text{alg}}[t]$. This polynomial having coefficients in $K$, we have $b_n^{(k)}(\theta) = 0$ if and only if the irreducible polynomial $t^{v_\mu} - \theta$ divides $b_{n_0}(t)$. However, this is impossible if $k > \log_q(\deg_t b_{n_0})$.

5.4 Construction of the auxiliary forms.

We recall the $u$-expansion of $E$ whose existence is proved in Proposition 11:

$$E = u \sum_{i \geq 0} c_i(t) v^i,$$

where $c_0 = 1, c_i \in \mathbb{F}_q[t,\theta]$ for all $i > 0$ and $v = u^{q-1}$.

Proposition 30 The following properties hold.

(i) Let $\alpha, \beta, \gamma, \delta$ be non-negative integers and let us write $f = g^\alpha h^\beta E^\gamma F^\delta \in \mathbb{M}_{\mu,\nu,m}^{\uparrow}$, with $\mu = \alpha(q-1) + \beta(q+1) + \gamma + \delta$, $\nu = \gamma + \delta$ and $\beta + \gamma + \delta \equiv m \pmod{q-1}$, $m \in \{0, \ldots, q-2\}$. Let us write

$$f = v^m \sum_{n \geq 0} a_n(t) v^n$$

with $a_n \in \mathbb{F}_q[t,\theta]$ (this is possible after Proposition 11 and the integrality of the coefficients of the $u$-expansions of $g, h$). Then, for all $n \geq 0$,

$$\deg_t a_n(t) \leq \nu \log_q \max\{1, n\}.$$

(ii) Let $\lambda$ be a positive real number. Let $f_1, \ldots, f_\sigma$ be a basis of monic monomials in $g, h, E, F$ of the $K$-vector space $\mathbb{M}_{\mu,\nu,m}^{\uparrow}(K)$. Let $x_1, \ldots, x_\sigma$ be polynomials of $\mathbb{F}_q[t,\theta]$ with $\max_{0 \leq i \leq \sigma} \deg_t x_i \leq \lambda$. Then, writing

$$f = \sum_{i=1}^\sigma x_i f_i = v^m \sum_{n \geq 0} b_n(t) v^n$$

with $b_n \in \mathbb{F}_q[t,\theta]$ with $0 \leq m \leq q-2$, we have, for all $n \geq 0$:

$$\deg_t b_n \leq \lambda + \nu \log_q \max\{1, n\}.$$

Proof. Since by definition $F = E^{(1)}$, we have

$$F = u^\lambda \sum_{n \geq 0} c_n^{(1)} v^{q^n} = u \sum_{r \geq 0} d_r v^r,$$

where $d_r = 0$ if $q \nmid r - 1$ and $d_r = c_n^{(1)}$ otherwise. Now, the operator $\tau$ leaves the degree in $t$ invariant. Therefore, by Proposition 11 $\deg_t d_r \leq \log_q \max\{1, r/q\} \leq \log_q \max\{1, r\}$.
Let us consider the $u$-expansions:
\[
\begin{align*}
g &= \sum_{n \geq 0} \gamma_n v^n, \\
h &= u \sum_{n \geq 0} \rho_n v^n, \\
E &= u \sum_{n \geq 0} c_n v^n, \\
F &= u \sum_{n \geq 0} d_n v^n,
\end{align*}
\]
with $\gamma_n, \rho_n \in A$, $c_n, d_n \in F_q[t, \theta]$ for all $n$, we can write:
\[
f = u^{m'} \sum_{n \geq 0} \kappa_n v^n,
\]
where $m' = \beta + \gamma + \delta$ and for all $n$, $\kappa_n = \sum \Pi_{x} \gamma_{i_{x}} \Pi_{y} \rho_{j_{y}} \Pi_{s} c_{k_{s}} \Pi_{z} d_{r_{z}}$, the sum being over the vectors of $\mathbb{Z}^{\alpha + \beta + \gamma + \delta}$ of the form
\[
(i_1, \ldots, i_{\alpha}, j_{1}, \ldots, j_{\beta}, k_{1}, \ldots, k_{\gamma}, r_{1}, \ldots, r_{\delta})
\]
whose sum of entries is $n$, and with the four products running over $x = 0, \ldots, \alpha$, $y = 0, \ldots, \beta$, $s = 0, \ldots, \gamma$ and $z = 0, \ldots, \delta$ respectively. Since the coefficients of the $u$-expansions of $g, h$ do not depend on $t$ and $\gamma + \delta = \nu$, we obtain $\deg_t \kappa_n \leq \nu \log_q \max\{1, n\}$.

If $m' = m + k(q - 1)$ with $k \geq 0$ integer, and $0 \leq m < q - 1$. We can write
\[
f = u^{m'} \sum_{n \geq 0} c'_{n-k} v^n = u^{m} \sum_{n \geq 0} c_n v^n,
\]
where $c_n = c'_{n-k}$, with the assumption that $c'_{n-k} = 0$ if the index is negative. The inequalities $\deg_t c'_{n} \leq \nu \log_q \max\{1, n\}$ for $n \geq 0$ imply that $\deg_t c_n$ is submitted to the same bound, proving the first part of the proposition. The second part is a direct application of the first and ultrametric inequality.

\[\square\]

5.4.1 Dimensions of spaces

Lemma 31 We have, for all $m$ and $\mu, \nu \in \mathbb{Z}$ such that $\mu \geq (q + 1)\nu \geq 0$,
\[
\sigma(\mu, \nu) - \nu - 1 \leq \dim_K M_{\mu,\nu,m}^\dagger(\mathbb{K}) \leq \sigma(\mu, \nu) + \nu + 1,
\]
where
\[
\sigma(\mu, \nu) = \left(\frac{(\nu + 1)\left(\mu - \frac{(q + 1)}{2}\right)}{q^2 - 1}\right).
\]

Therefore, if $\mu > \frac{(q + 1)}{2} + q^2 - 1$, we have $\dim_K M_{\mu,\nu,m}^\dagger(\mathbb{K}) > 0$.

Proof. By [12] p. 33, we know that
\[
\delta(k, m) := \dim_C M_{k,m} = \left\lfloor \frac{k}{q^2 - 1} \right\rfloor + \dim_C M_{k^*, m},
\]
where $k^*$ is the remainder of the euclidean division of $k$ by $q^2 - 1$. In the same reference, it is also proved that $\dim_C M_{k,m} = 0$ unless $k^* \geq m(q + 1)$, case where $\dim_C M_{k^*, m} = 1$, so that, in all cases, $0 \leq \dim_C M_{k^*, m} \leq 1$.

A basis of $M_{\mu,\nu,m}^\dagger(\mathbb{K})$ is given by:
\[
(b_k)_{k=1, \ldots, \dim M_{\mu,\nu,m}^\dagger(\mathbb{K})} = (\phi_{i,s} h^s E^{q-s})_{s=0, \ldots, \nu; i=1, \ldots, \sigma(s)}, \tag{56}
\]

27
with, for all $s$, $(\phi_{i,s})_{i=1,\ldots,\sigma(s)}$ a basis of $M_{\mu-s(q-1)-\nu,m-\nu}$ (hence $\sigma(s) = \delta(\mu-s(q-1)-\nu, m-\nu)$).

We have (taking into account the hypothesis on $\mu$ which implies $\mu - s(q-1) - \nu > 0$ for all $0 \leq s \leq \nu$):

$$
\dim M^{\dagger}_{\mu,\nu,m}(K) = \sum_{s=0}^{\nu} \delta(\mu - \nu - s(q-1), m - \nu)
$$

But

$$
\sum_{s=0}^{\nu} \frac{\mu - s(q-1) - \nu}{q^2 - 1} = \sigma(\mu, \nu).
$$

Moreover, $\mu > \frac{\nu(q+1)}{2} + q^2 - 1$ if and only if $\sigma(\mu, \nu) > \nu + 1$, from which we deduce the lemma easily.

5.4.2 Applying a variant of Siegel’s Lemma

We now prove the following:

**Proposition 32** Let $\mu, \nu \in \mathbb{Z}_{\geq 0}$ be such that

$$
\mu \geq (q+1)\nu + 2(q^2 - 1) \tag{57}
$$

with $\nu \geq 1$, let $m$ be an integer in $\{0,\ldots,q-2\}$. There exists an integer $r > 0$ such that

$$
r \leq 4q\mu \nu \log q(\mu + \nu + q^2 - 1) + \nu \tag{58}
$$

and, in $\tilde{M}^{\leq \nu}_{r,m}$, a quasi-modular form $f_{\mu,\nu,m}$ such that

$$
\frac{1}{q(q+1)}\nu^2 \log_q(\mu + \nu + q^2 - 1) \leq \nu_{\infty}(f_{\mu,\nu,m}) \leq 4q\mu^2 \log_q(\mu + \nu + q^2 - 1). \tag{59}
$$

We will need the following variant of Siegel’s Lemma whose proof can be found, for example, in [16, Lemma 1] (see also [7]).

**Lemma 33** Let $U, V$ be positive integers, with $U < V$. Consider a system \((60)\) of $U$ equations with $V$ indeterminates:

$$
\sum_{i=1}^{V} a_{i,j} x_i = 0, \quad (1 \leq j \leq U) \tag{60}
$$

where the coefficients $a_{i,j}$ are elements of $K[t]$. Let $d$ be a non-negative integer such that $\deg_i a_{i,j} \leq d$ for each $(i,j)$. Then, \((60)\) has a non-zero solution $(x_i)_{1 \leq i \leq V} \in (K[t])^V$ with $\deg_i x_i \leq Ud/(V-U)$ for each $i = 1,\ldots,V$.

**Proof of Proposition 32** We apply Lemma 33 with the parameters $V = \dim M^{\dagger}_{\mu,\nu,m}(K)$, $U = \lfloor V/2 \rfloor$. We know that $V > 0$ because of \((57)\) and Lemma 33.

If $f = b_i$ as in \((56)\), Writing

$$
b_i = u \sum_{j \geq 0} a_{i,j} v^j, \quad a_{i,j} \in A[t] \tag{61}
$$

28
with $0 \leq m < q - 1$, Proposition 30 says that for all $i$ and for all $j \geq 0$,
\[ \deg_t a_{i,j} \leq \nu \log_q \max \{1, j\}. \] (62)

Lemma 33 yields polynomials $x_1, \ldots, x_V \in K[t]$, not all zero, such that if we write
\[ f = \sum_i x_i b_i = u^m \sum_{n \geq n_0} b_n v^n, \quad 0 \leq m < q - 1 \] (63)
with $b_n \in K[t]$ for all $n$ and $b_{n_0} \neq 0$, we have the following properties. The first property is the last inequality below:
\[ m + (q - 1) n_0 = \nu_{\infty}(f) \geq m + (q - 1) U \]
\[ \geq (q - 1)(\sigma(\mu, \nu) - \nu - 1)/2 - 1 \]
\[ \geq \frac{\nu + 1}{2(q + 1)} (\nu + 1) (q^2 - 1) \]
\[ \geq \nu_{\infty}(f) \geq \frac{1}{4(q + 1)} (\nu + 1) \mu - 1, \] (64)
where we have applied Lemma 31 and (57). The second property is that, in (63),
\[ \deg_t b_n \leq 2\nu(\log_q (\mu + \nu + q^2 - 1) + \log_q \max \{1, n\}) \quad n \geq 0, \] (65)
which follows from the following inequalities, with $d = \nu \log_q \max \{1, U\}$
\[ \deg_t x_i \leq Ud/(V - U) \]
\[ \leq \nu \log_q \max \{1, U\} \]
\[ \leq \nu \log_q ((\sigma(\mu, \nu) + \nu + 1)/2) \]
\[ \leq \nu(\log_q (\nu + 1) + \log_q (\mu + q^2 - 1) - \log_q (q^2 - 1)) \]
\[ \leq 2\nu \log_q (\mu + \nu + q^2 - 1), \]
and Proposition 30.

By Proposition 26 we have $m + (q - 1)n_0 = \nu_{\infty}(f) \leq \mu \nu$ so that $n_0 \leq \frac{\mu \nu}{q^2 - 1}$, where $n_0$ is defined in (63). Hence, by (65),
\[ \deg_t b_{n_0} \leq 4\nu \log_q (\mu + \nu + q^2 - 1). \] (66)

Lemma 29 implies that for every integer $k$ such that
\[ k \geq \log_q (4\nu) + \log_q \log_q (\mu + \nu + q^2 - 1), \] (67)
the function $f_k := \varepsilon(f^{(k)})$ satisfies $\nu_{\infty}(f_k) = \nu_{\infty}(f^{(k)}) = q^k \nu_{\infty}(f)$. Let $k$ be satisfying (67). We have, by (64), Proposition 26 and (54):
1. $f_k \in \overline{M_{\mu q^k + \nu, m}}$
2. $\left(\frac{(\nu + 1)\mu q^k}{4(q + 1)} - 1\right) \leq \nu_{\infty}(f_k) \leq \mu \nu q^k$

Let us define the function
\[ \kappa(\mu, \nu) := [\log_q (4\nu) + \log_q \log_q (\mu + \nu + q^2 - 1)] + 1 \]
and write: $f_{\mu, \nu, m} := f_{\kappa(\mu, \nu)}$. This Drinfeld quasi-modular form satisfies the properties announced in the proposition. \qed

29
5.5 Proof of Theorem 1

Let \( f \) be a Drinfeld quasi-modular form of weight \( w \) and depth \( l \). We can assume, without loss of generality, that \( f \), as a polynomial in \( E, g, h \) with coefficients in \( C \), is an irreducible polynomial. We can also assume, by Gekeler, \([11\, Formula\,(5.14)]\) and \([4\, Theorem\,1.4]\), that \( l > q \).

Let \( W \) be a real number \( \geq 1 \) and let \( \alpha \) be the function of a real variable defined, for \( \mu \geq 0 \), by

\[
\alpha(\mu) = \mu l \log_q (\mu + Wl + q^2 - 1);
\]

we have

\[
\alpha'(\mu) > 1 \quad \text{for all} \quad l \geq q \quad \text{and} \quad \mu \geq 0, \quad \text{for all} \quad w \geq 0 \quad \text{integer}, \quad \text{there exist} \quad \mu \in \mathbb{Z}_{\geq 0} \quad \text{such that}
\]

\[
\alpha(\mu) \leq w < \alpha(\mu + 1), \quad (68)
\]

and we choose one of them, for example the biggest one. Let us suppose that \( 4 \) holds and, at once, set

\[
\nu = Wl,
\]

with

\[
W = q(2 + 4(q + 1)) = 2q(3 + 2q).
\]

We define \( \beta(l) \) to be the right hand side of \( 4 \), as a function of \( l \geq q \). Condition \( 4 \) implies

\[
\mu \geq \frac{\beta(l)}{2l \log_q (\mu + Wl + q^2 - 1)}.
\]

Since \( \log_q(x) \leq 2x^{1/2} \) for all \( x \geq 1 \) and \( q \geq 2 \), we get

\[
(\mu + Wl + q^2 - 1)^{3/2} \geq \frac{\beta(l)}{4l}.
\]

that is,

\[
\mu \geq \left( \frac{\beta(l)}{4l} \right)^{2/3} - Wl - q^2 + 1.
\]

But replacing \( \beta(l) \) by its value yields \( \mu \geq (q + 1)\nu + 2(q^2 - 1) \), which is the condition \( 57 \) needed to apply Proposition 32.

Let us write \( L := \log_q (\mu + \nu + q^2 - 1) \) so that \( \alpha(\mu) = \mu l L \). By Proposition 32 there exists a form \( f_{\mu,\nu,m} \in \tilde{M}^{\leq \nu}_{\leq m} \) such that \( l(f_{\mu,\nu,m}) \leq \nu \) and

\[
(q(\nu + 1))^{-1} \mu \nu^2 L \leq \nu_{\infty}(f_{\mu,\nu,m}) \leq 4(q + 1)\mu \nu L \leq 4q\mu \nu^2 L \quad (69)
\]

We have two cases.

Case (i). If \( f \mid f_{\mu,\nu,m} \), then

\[
\nu_{\infty}(f) \leq \nu_{\infty}(f_{\mu,\nu,m}) \leq 4q\mu \nu^2 L \quad (70)
\]

Case (ii). If \( f \not\mid f_{\mu,\nu,m} \), then \( \rho := \text{Res}_E(f, f_{\mu,\nu,m}) \) is a non-zero modular form, whose weight \( w(\rho) \) and type \( m(\rho) \) can be computed with the help of \([4\, Lemma\,2.5]\) (we do not need an explicit computation of \( m(\rho) \)):

\[
w(\rho) = \nu + w(f_{\mu,\nu,m})l - 2l\nu \\
\leq \nu + 4(q + 1)\mu \nu L - 2l\nu \\
\leq \nu(w + 4(q + 1)\mu L) \\
\leq \nu(\alpha(\mu + 1) + 4(q + 1)\mu L) \\
\leq \nu(2\alpha(\mu) + 4(q + 1)\mu L) \\
\leq (2 + 4(q + 1))\nu \mu l L \quad (71)
\]
Let us suppose that $\nu_\infty(f) > (q(q+1))^{-1}\mu^2\mathcal{L}$. Then, by Bézout identity for the resultant and \(69\), $\nu_\infty(\rho) \geq (q(q+1))^{-1}\mu^2\mathcal{L}$. At the same time, by Gekeler, \([11\text{, Formula (5.14)}]\), $\nu_\infty(\rho) \leq \frac{w(\rho)}{q^2}$, yielding the inequality $W < q(2+4(q+1))$ which is contradictory with the definition of $W$.

Therefore, in case (ii), we have that $\nu_\infty(f) \leq 4\mu\nu^2\mathcal{L}$. Ultimately, we have shown that, in both cases (i), (ii),

$$
\nu_\infty(f) \leq 4\mu\nu^2\mathcal{L} \\
\leq 4\mu W^2t^2\mathcal{L} \\
\leq 4W^2lw,
$$

which is the estimate (3).

\[\square\]

**Remark 34** The dependence on $l$ in condition (4) can be relaxed, adding conditions on $q$. For all $\epsilon > 0$ there exists a constant $c > 0$ such that for all $q > c$, assuming that $w \gg l^{2+\epsilon}$, then, the inequality (3) holds. We do not report the proof of this fact here.

**Acknowledgement.** The author is indebted with V. Bosser for several discussions on these topics and a careful reading of the first versions of this paper.
