Abstract. An Input Output Symbolic Transition System (IOSTS) specifies all expected sequences of input and output messages of a reactive system. Symbolic execution over this IOSTS then allows to generate a set of test cases that can exercise the various possible behaviors of the system it represents. In this paper, we extend the IOSTS framework with explicit program calls, possibly equipped with contracts specifying what the program is supposed to do. This approach bridges the gap between a model-based approach in which user-defined programs are abstracted away and a code-based approach in which small pieces of code are separately considered regardless of the way they are combined. First, we extend symbolic execution techniques for IOSTS with programs, in order to re-use classical test case generation algorithms. Second, we explore how constraints coming from IOSTS symbolic execution can be used to infer contracts for programs used in the IOSTS.

Keywords: Input Output Symbolic Transition Systems, Program Contracts, Model-based Testing, Symbolic Execution, Feasibility.

1 Introduction

Symbolic transition systems, such as Input Output Symbolic Transition Systems (IOSTS) [10] are a classical reference modeling framework for model-based testing of reactive systems. They provide a convenient abstraction of the behaviors of such systems by modeling system state evolution using variable assignments. The symbolic execution tree of an IOSTS characterizes the different classes of numeric executions. Each path defines a sequence of symbolic inputs and outputs, and a path condition which is a formula constraining the values exchanged (inputs or outputs) with the environment of the system. It is possible to use such paths as reference symbolic behaviors to be tested (i.e. as test purposes). In [10], we have proposed a framework to analyze IOSTS both to extract such test purposes and to solve the oracle problem thanks to a fully on-line algorithm. However, this kind of framework is limited by the symbolic treatment of functions. Indeed, IOSTS variables are assigned by terms built on functions. In order
to be able to reason on the symbolic values assigned to variables, the symbolic execution engine is equipped with constraint solving techniques able to analyze those functions. As long as one deals with basic arithmetic or boolean functions, it is generally tractable, but as soon as one deals with user-defined or ad-hoc functions, solving techniques may fail to scale, or even, due to undecidability results, such techniques may not exist. Analyzing such functions (later referred as ”programs”) may require both to deal with sophisticated data structures and to explore their (arbitrarily complex) control graph.

In this paper we propose an approach to overcome this limitation by abstracting program behaviors by means of contracts \cite{17}. A contract for a program consists in a collection of couples, also called behaviours, formed of a pre-condition that specifies constraints that the caller must enforce at the call site, and a post-condition which is a property guaranteed at the program return. We enrich the basic IOSTS framework to deal with program calls equipped with contracts. We show how to extend symbolic execution mechanisms to reason about IOSTS equipped with program calls by analyzing those calls through their contracts. Thus, we avoid analyzing the actual behavior of the program and replace it by abstract constraints on its formal parameters. Our framework allows computing symbolic paths that can be used as test purposes. It may happen that guards and contracts are incompatible so that some symbolic paths are infeasible (i.e. they have no associated trace). In practice it means that there exists no program that can both satisfy its associated contracts and compute values allowing to follow the whole symbolic path. We show how to use symbolic techniques to check that a given set of symbolic paths is consistent with respect to program calls.

Moreover, since guards occurring on transitions of an IOSTS interact with contracts associated to programs, we present an approach to extract new contracts for each of the program exercised. Such contracts reflect constraints on the program that make the path feasible. As such, they represent new contracts that can be used at the unitary level, to evaluate the correctness of actual program used to implement the system under test.

The remaining of the paper is organized as follows. In Section 2, we give basic definitions about many-typed first order logic. Section 3 presents programs and their contracts. In Section 4 we introduce IOSTS with programs. Section 5 defines symbolic execution of an IOSTS with programs and the associated feasibility condition. Usage of symbolic execution for testing purposes, including contract inference for unitary testing is introduced in Section 6. In Section 7, we give a detailed example of a vending machine modelled by an IOSTS enriched by program calls: in particular, it includes a program in charge of computing the giving of change in function of coins inserted by the user and of the machine reserve.
2 Preliminaries

For two sets $A$ and $B$, $B^A$ denotes the set of mappings $f : A \to B$ from $A$ to $B$ and $id_A$ is the identity mapping on $A$. For a mapping $f : A \to B$, $f[a_i \mapsto b_i]_{i \in 1..n}$ is the mapping associating $b_i$ to $a_i$ for all $i$ in $1..n$ and $f(a)$ to a not belonging to $\{a_i | i \in 1..n\}$. By convention, $[a_i \mapsto b_i]_{i \in 1..n}$ stands for $id_A[a_i \mapsto b_i]_{i \in 1..n}$.

For two mappings $f : A_1 \to B$ and $g : A_2 \to B$ with $A_1 \cap A_2 = \emptyset$, $f \cup g : A_1 \cup A_2 \to B$ is the mapping defined by: $\forall a \in A_1, (f \cup g)(a) = f(a)$ and $\forall a \in A_2, (f \cup g)(a) = g(a)$. $A^*$ (resp. $A^+$) denotes the set of words on $A$ provided with the concatenation operator · and the empty word $\varepsilon$ (resp. deprived of the empty word $\varepsilon$). For an ordered list $l = (a_1, \ldots, a_n)$ of $n$ elements of $A$, $\{l\}$ denotes the set $\{a_1, \ldots, a_n\}$ of elements occurring in $l$.

We use classical multi-typed first order logic to handle data. A data signature is a pair $(S, F)$ where $S$ is a set of so-called types and $F$ is a set of functions provided with a profile $s_1 \cdots s_{n-1} \to s_n$ with each $s_i \in S$. For $V = \coprod_{s \in S} V_s$, a set of variables typed in $S$, the set $T_F(V) = \coprod_{s \in S} T_F(V)_s$ of so-called functional terms over $V$ is defined as usual over $(S, F)$. Moreover, each set $V_s$ contains an identified subset, denoted $V_s^{fr}$, whose elements are called frozen variables and we denote $V^{fr} = \coprod_{s \in S} V_s^{fr}$ the subset of $V$ of all frozen variables. The set $Sen_F(V)$ of formulas is built over Boolean constants $\top$ and $\bot$, equalities $t = t'$ for $t$ and $t'$ terms in $T_F(V)$ of same type and usual Boolean connectives ($\land, \lor, \neg, \ldots$). Substitutions over $V$ are applications $\sigma : V \to T_F(V)$ that preserve types and are such that all elements of $V^{fr}$ are frozen for $\sigma$ (i.e. $\forall v \in V^{fr}, \sigma(v) = v$).

Thus, as frozen variables cannot be substituted, they may be considered as new special constants. Substitutions can be canonically extended to $T_F(V)$. For a term $t$ in $T_F(V)$, for a formula $\varphi$ in $Sen_F(V)$, $Occ(t)$ and $Occ(\varphi)$ will denote the set of variables occurring in respectively $t$ and $\varphi$.

A $F$-model is a set of typed variables $M = \coprod_{s \in S} M_s$ provided with a function $\vec{f} : M_{s_1} \times \cdots \times M_{s_{n-1}} \to M_{s_n}$ for each $f : s_1 \cdots s_{n-1} \to s_n$ in $F$. An interpretation is an application $\nu : M^V$ that preserves types and can be canonically extended to $T_F(V)$. The satisfaction of a formula $\varphi$ in $Sen_F(V)$ by an interpretation $\nu \in M^V$, denoted $M \models_\nu \varphi$, is defined as usual by considering the meaning of the equality predicate, Boolean constants and connectives. A formula $\varphi$ in $Sen_F(V)$ is valid if and only if for all interpretations $\nu : V \to M$, $M \models_\nu \varphi$.

In the sequel, data signature $(S, F)$ and $F$-model $M$ are supposed given.

3 Programs and contracts

Programs. User-defined functions, called programs, are identifiers provided with an interface specifying their formal parameters used to store input and output data. We only consider here programs with no side effect and one output variable.

Definition 1 (Program). Let $X = \coprod_{s \in S} X_s$ be a set of typed variables. A program over $X$ is an identifier $p$ provided with:
- a list \( \text{InOut}(p) = (x_1, \ldots, x_{n+1}) \in X^{n+1} \), called the interface of \( p \), with \( n \geq 1 \) and \( \forall i \neq j, x_i \neq x_j \). \( \text{In}(p) \) (resp. \( \text{Out}(p) \)) denotes the list \( (x_1, \ldots, x_n) \) (resp. \( (x_{n+1}) \)) of input (resp. output) formal parameters of \( p \).
- and a mapping \( \text{Sem} : M^\mathcal{L}(\text{In}(p)) \rightarrow M^\mathcal{L}(\text{InOut}(p)) \), called the semantics of \( p \), verifying the so-called semantic condition:
  \[ \forall \nu \in M^\mathcal{L}(\text{In}(p)), \forall x_j \in \mathcal{L}(\text{In}(p)), \text{Sem}(\nu)(x_j) = \nu(x_j). \]

Depending on the values associated to \( \text{In}(p) \) through the interpretation \( \nu \), \( \text{Sem} \) associates a value to the formal parameter \( x_{n+1} \) in \( \text{Out}(p) \). The semantic condition ensures that a program call has no effect on its input formal parameters. By extrapolation, given a list \( l = (x_1, \ldots, x_{n+1}) \), \( \text{In}(l) \) and \( \text{Out}(l) \) will resp. denote \((x_1, \ldots, x_n)\) and \((x_{n+1})\).

A signature \( \Sigma \) is a tuple \( (S,F,X,P) \) where \( (S,F) \) is a data signature and \( P \) is a set of programs defined over the set of typed variables \( X \).

Let \( V = \prod_{s \in S} V \) be a set of typed variables. The set \( T_{\Sigma}(V) = \prod_{s \in S} T_{\Sigma}(V)_s \) of typed terms over \( V \) contains:

- all functional terms of \( T_F(V) \)
- all elements \( p(t_1, \ldots, t_n) \) with \( p \in P \) of interface \( (x_1, \ldots, x_{n+1}) \), \( \forall 1 \leq i \leq n, x_i \in X_s \), and \( t_i \in T_F(V)_s \). If \( x_{n+1} \in V_s \), \( p(t_1, \ldots, t_n) \in T_{\Sigma}(V)_s \).

Any interpretation \( \nu : V \rightarrow M \) can be canonically extended on \( T_{\Sigma}(V) \) as follows: for any program \( p \) in \( P \) defined by its interface \( (x_1, \ldots, x_{n+1}) \) and its semantics \( \text{Sem}_p \), let us consider \( \mu^\nu_p : \mathcal{L}(\text{In}(p)) \rightarrow M \) an interpretation such that \( \forall 1 \leq i \leq n, \mu^\nu_p(x_i) = \nu(t_i) \), we have \( \nu(p(t_1, \ldots, t_n)) = \text{Sem}_p(\mu^\nu_p)(x_{n+1}) \).

Contracts. Contracts specify what programs are expected to compute, as opposed to how they compute their result. They have been introduced in the pioneering work of Floyd [9] and Hoare [11], and form a key ingredient of the Eiffel programming language [17]. In short, a contract describes what a program requires from its caller (the pre-condition) and what it guarantees when it returns (the post-condition). We use here a slightly refined notion where a contract can be split in a set of behaviors [2,4]. In this setting, pre-condition of a behavior indicates a possible case in which the program may be executed. As before, when a behavior is active, its post-condition must hold at the end of the execution.

Most of the times, pre and post conditions of a program are simply formulas in resp. \( \text{Sen}_F(\mathcal{L}(\text{In}(p))) \) and \( \text{Sen}_F(\mathcal{L}(\text{Out}(p))) \). However, contracts can involve other variables representing the global state of the system. The latter will be frozen variables whose associated values are conditioned by axioms and cannot be modified. These variables will be useful for inferring contracts from symbolic execution tree, as shown in Section [9,22].

**Definition 2 (Program contract).** Let \( l = (x_1, \ldots, x_{n+1}) \) be a list of variables with \( \forall i \leq n+1, x_i \in X \). Let \( W \) be a subset of frozen variables verifying \( X \cap W = \emptyset \). A program contract for \( l \) and \( W \) is a set:

\[ \{ (\text{Pre}_1, \text{Post}_1), \ldots, (\text{Pre}_k, \text{Post}_k) \} \]
such that \( \forall i \leq k, \text{Pre}_i \in \text{Sen}_F(\{\text{In}(l)\} \cup W) \) and \( \text{Post}_i \in \text{Sen}_F(\{l\} \cup W) \).

A program contract is said to be:

- disjoint if for all \( i, j \leq k \) with \( i \neq j \), the formula \( \neg(\text{Pre}_i \land \text{Pre}_j) \) is valid.
- complete if the formula \( \bigvee_{i \leq k} \text{Pre}_i \) is valid.

Disjointness requires that at most one behavior of the contract is applicable for any considered input data, i.e. the pre-conditions are mutually exclusive. For simplicity purpose, we only consider disjoint contracts in this paper. Completeness indicates that for any input at least one behavior is applicable. In practice, programs are often partially defined over their input domain. We thus allow incomplete contracts, rejecting input data outside the scope of preconditions.

**Example 1.** Let us consider a program \( \text{Price} \) of interface \((x_1, x_2)\) where \( x_1 \) is of type \( \text{Drink} \), an enumerated type with two values \( \{0, 1\} \) and \( x_2 \) is of type \( \text{Integer} \). \( x_1 \) is the input parameter indicating the selected beverage and \( x_2 \) is the output parameter corresponding to its price. An example of contract for \( \text{Price} \) is \( C_r = \{(\text{Pre}_1, \text{Post}_1), (\text{Pre}_2, \text{Post}_2)\} \) (both disjoint and complete), with:

- \( \text{Pre}_1: x_1 = 0, \text{Post}_1: x_2 \geq 100 \land x_2 \leq 200 \)
- \( \text{Pre}_2: x_1 = 1, \text{Post}_2: x_2 \geq 200 \land x_2 \leq 300 \)

**Definition 3 (Contract satisfaction).** Let \( l = (x_1, \ldots, x_{n+1}) \) be an interface, \( W \) a set of frozen variables provided with \( Ax \subseteq \text{Sen}_F(W) \) and \( C \) a contract for \( l \) and \( W \). Let us consider an interpretation \( \nu \in M^W \) such that \( M \models_{\nu} Ax \) and a mapping \( \text{Sem} : M^{|\text{In}(l)|} \to M^{|l|} \) satisfying the semantic condition.

\( \text{Sem} \) satisfies \( C \) up to \( \nu \), denoted \( \text{Sem} \models_{\nu} C \), if and only if:

\[
\forall (\text{Pre}, \text{Post}) \in C, \forall \mu \in M^{|\text{In}(l)|}, M \models_{\nu \cup \mu} \text{Pre} \Rightarrow M \models_{\nu \cup \text{Sem}(\mu)} \text{Post}
\]

\( \text{Sem}_{\nu}(C) = \{ \text{Sem} : M^{|\text{In}(l)|} \to M^{|l|} | \text{Sem} \models_{\nu} C \} \) denotes the set of semantics satisfying \( C \) up to \( \nu \).

For each interface \( l \), we consider the trivial contract \( C_{\emptyset, l} = \{\} \), simply denoted \( C_{\emptyset} \), defined on \( l \) that does not restrict behaviors of programs, that is \( p \in \text{Sem}(C_{\emptyset}) \) for all programs \( p \) of interface \( l \). Similarly, we consider the contract \( C_{\top, l} = \{\{\top, \top\}\} \), simply denoted \( C_{\top} \), defined on \( l \) that requires that the program is defined for every well-typed input data tuple.

Given a signature \( \Sigma = (S, F, X, P) \), a set of frozen variables \( W \) with its set of axioms \( Ax \subseteq \text{Sen}_F(W) \), and an interpretation \( \nu \in M^W \) verifying \( M \models_{\nu} Ax \), we consider families \( \mathbb{C} = (C_p)_{p \in P} \) of contracts indexed by \( P \), in particular \( \mathbb{C}_{\emptyset} = (C_{\emptyset})_{p \in P} \) and \( \mathbb{C}_{\top} = (C_{\top})_{p \in P} \). \( \text{Mod}_{\nu}(\mathbb{C}) \) is the set of all families \( \text{Sem} = (\text{Sem}_p)_{p \in P} \) such that \( \forall p \in P, \text{Sem}_p \models_{\nu} C_p \). \( \text{Sem} \) is then called a \( P \)-model.

**4 IOSTS**

Input Output Symbolic Transition Systems (IOSTS) represent behaviors of reactive systems as sequences of emissions or receptions of values through communication channels conditioned by guards expressed on some attribute values.
An IOSTS-signature $\Gamma$ is a couple $(A, Ch)$, where $A = \prod_{s \in S} A_s$ is a set of types variables, called attribute variables, such that for all $s$ in $S$, $A_s \cap X_s = \emptyset$ and where $Ch$ is a set of communication channel names.

An IOSTS communicates with its environment through communication actions. The set of symbolic actions over $\Gamma$, denoted $Act(\Gamma)$, is $I(\Gamma) \cup O(\Gamma) \cup \{\top\}$ where: $I(\Gamma) = \{c?x| x \in A, c \in Ch\}$ is the set of inputs, $O(\Gamma) = \{c!t| t \in T_{\Sigma}(A), c \in Ch\}$ is the set of outputs and $\top$ is an internal action.

Values of attribute variables can be modified in two ways: by receiving a value from the environment or by assigning a value from some internal process.

**Definition 4 (IOSTS).** An IOSTS $(Q, q_0, Tr)$ over $\Sigma$ and $\Gamma = (A, Ch)$ is a triple where $Q$ is a set of states, $q_0 \in Q$ is the initial state and $Tr \subseteq Q \times Sen_F(A) \times Act(\Gamma) \times T_{\Sigma}(A)^A \times Q$ is a set of transitions $tr$ of the form $(q, \psi, act, \rho, q')$ where:
- $q$ and $q'$ are resp. the source (source($tr$)) and target state (target($tr$)) of $tr$,
- $\psi \in Sen_F(A)$ is a guard
- $act \in Act(\Gamma)$ is a communication action;
- $\rho \in T_{\Sigma}(A)^A$ is a substitution associating a term to attribute variables;

**Remark 1.** We can always consider an IOSTS in which guards only contain conjunctions. If not, for a transition $tr$ of guard $\psi$, it suffices to use a disjunctive normal form $\bigwedge_{i=1}^n \psi_i$ equivalent to $\psi$ and to split the transition into $n$ transitions having the same source, target and communication action as $tr$ and $\psi_i$ as guard.

**Example 2 (Drink vending machine).** We consider a very simple drink vending machine. Its behavior is specified by the IOSTS in Fig. 3. An initialization step $(q \rightarrow q_0)$ sets the amount to zero. Then, in $q_0$, the machine waits for an amount $(x)$ of coins introduced by the user, and updates the amount $m$. The user then chooses his/her beverage (0 or 1 for "Tea" or "Coffee"). The choice is stored in variable $B$. In the transition $q_2 \rightarrow q_3$, the program $Price$ computes the price of the chosen drink. Two cases are possible here. If the introduced amount is lower than the price ($m < p$), then a message "Add" appears on the screen and the machine returns to $q_0$. Otherwise ($m \geq p$), the drink is delivered, the amount is reinitialized to zero and the machine goes back to $q_0$. Note that transitions outgoing from $q_3$ constrain the value $(p)$ computed by $Price$ ($p \geq 150 \land p \leq 200$).

For a transition $tr = (q, \psi, act, \rho, q') \in Tr$ and a $P$-model $Sem$, the semantics of $tr$, denoted as $Run(tr, Sem) \subseteq M^A \times Act^{M}(\Gamma) \times M^A$, is defined as the set of triple $(\nu_i, act_M, \nu_f)$ verifying:
- if act is of the form $c!t$ (resp. $\top$), then $M \models_{\nu_i} \psi, \nu_f = \nu_i \circ \rho$ and $act_M = c!\nu_i(t)$ (resp. $act_M = \top$)
- if act is of the form $c?x$, then $M \models_{\nu_i} \psi$, there exists $\nu_a$ such that $\nu_a(z) = \nu_i(z)$ for every $z \neq x$, $\nu_f = \nu_a \circ \rho$ and $act_M = c?\nu_a(x)$,

Note that the definition of semantics of transitions is very classical and does not explicitly refers to $Sem$. In fact, semantics of programs are taken into account when defining $\nu_f$ from the extensions of $\nu_i$ or $\nu_a$ to $T_{\Sigma}(A)$ as defined in Section 3.
Definition 5 (Path feasibility condition). Let $G = (Q, q_0, Tr)$ be an IOSTS over $\Gamma = (A, Ch)$ and $pa$ a path of $G$. $pa$ is a feasible path if and only if:

$$\exists \text{Sem} \in \text{Mod}(C_{q_0}), \text{Traces}(pa, \text{Sem}) \neq \emptyset$$

Let $W$ be a set of frozen variables provided with $Ax \subseteq \text{Sen}_F(W)$ and $\nu \in M^W$ an interpretation satisfying $M \models_\nu Ax$. Let us consider $C = (C_p)_{p \in P}$ a family of contracts indexed by $P$. $pa$ is a feasible path up to $(\nu, C)$ if and only if:

$$\exists \text{Sem} \in \text{Mod}_\nu(C), \text{Traces}(pa, \text{Sem}) \neq \emptyset$$

5 Symbolic Execution and path feasibility condition

Symbolic execution consists in executing an IOSTS for symbolic values (taken from a dedicated set of frozen variables $Fr = \coprod_{s \in S} Fr_s$) rather than numerical
ones, and computing constraints on those values for all possible IOSTS executions. The main novelties with respect to [10] are twofold: substitutions occurring in transitions may include program calls and a renaming mechanism ensures that a given frozen variable can not appear in two distinct paths.

To store information concerning an execution, we use structures called symbolic states. A symbolic state is a tuple of the form $(q, \pi, \lambda, \kappa)$ where $q \in Q$, $\pi \in Sen_F(\mathcal{F}_r)$, $\lambda : A \rightarrow T_F(\mathcal{F}_r)$ is an application preserving types and $\kappa \subseteq P \times T_F(\mathcal{F}_r)^* \times \mathcal{F}_r$. For a symbolic state $\eta = (q, \pi, \lambda, \kappa)$, $q$ (or $q(\eta)$) denotes the state reached after an execution leading to $\eta$, $\pi$ (or $\pi(\eta)$) is a constraint on variables in $\mathcal{F}_r$ called path condition that should be satisfied for the execution to reach $\eta$, $\lambda$ (or $\lambda(\eta)$) denotes terms over variables in $\mathcal{F}_r$ that are assigned to variables of $A$ and $\kappa$ (or $\kappa(\eta)$) denotes the set of tuples of the form $(p, (t_1, \cdots, t_n), x)$ indicating that a program call has been performed for the program $p$ with the arguments $(t_1, \cdots, t_n)$ and that its result is stored in the variable $x$ in $\mathcal{F}_r$.

In our approach we do not have the code of programs. Instead, we reason on their contracts. Since the input formal parameters associated to a call are represented symbolically by functional terms $t_1, \cdots, t_n$, different pre-conditions may hold depending on the way those terms will be interpreted. At the symbolic execution level, we thus consider a sub-case for each of those pre-conditions. More precisely, the symbolic execution of a transition $tr$ from a given symbolic state $\eta$ will consist in a set of symbolic transitions, one for each possible combination of pre-conditions for all program calls occurring in $tr$. We now introduce some notations aiming at tracing program calls: for a substitution $\rho : A \rightarrow T_\Sigma(A)$ and for $p \in P$, $Res(p, \rho)$ is the set of variables $y \in A$ such that $\rho(y)$ is of the form $p(t_1, \cdots, t_n)$ and for such an $y$, $Arg(y, \rho)$ is then $(t_1, \cdots, t_n)$ and $Prog(y, \rho) = p$.

We also denote $Res(\rho)$ for $\bigcup_{p \in P} Res(p, \rho)$.

**Definition 6 (Symbolic execution of transitions).** Let $\mathbb{G} = (Q, q_0, Tr)$ be an IOSTS over $\Sigma$ and $F = (A, Ch)$, $tr = (q, \psi, act, \rho, q') \in Tr$ be a transition and $\eta = (q, \pi, \lambda, \kappa)$ be a symbolic state over $\mathbb{G}$.

If $act$ is of the form $c?x$, $\lambda_i = [x \mapsto f]$, $f$ fresh in $\mathcal{F}_r$. Otherwise, $\lambda_i = \lambda$. $\lambda'$ is the substitution such that for all $y \in Res(\rho)$, $\lambda'(y)$ is a fresh variable of $\mathcal{F}_r$ and for all $y \in A \setminus Res(\rho)$, $\lambda'(y) = \lambda_i \circ \rho(y)$.

The symbolic execution $SE(tr, \eta)$ of $tr$ from $\eta$ is the set defined as follows:

- if $Res(\rho) = \emptyset$ then $SE(tr, \eta) = \{(\eta, \lambda_i(\text{act}), \eta')\}$ with $\eta' = (q', \pi \land \lambda(\psi), \lambda', \kappa')$.
- if $Res(\rho) \neq \emptyset$, for any mapping $Beh : Res(\rho) \rightarrow \bigcup_{p \in P} C_p$ such that for $y \in Res(p, \rho)$, $Beh(y) = (Pre_y, Post_y) \in C_p$. For $y \in Res(p, \rho)$ with $InOut(p) = (x_1, \cdots, x_n, x_{n+1})$ and $Arg(y, \rho) = (t_1, \cdots, t_n)$, we have $(\eta, \lambda_i(\text{act}), \eta') \in SE(tr, \eta)$ with

  - $\eta'$ the symbolic state $(q', \pi \land \lambda(\psi) \land \bigwedge_{y \in Res(\rho)} \Delta(y), \lambda', \kappa')$
  - $\Delta(y) = (Pre_y \land Post_y)[x_1 \mapsto \lambda_i(t_1) \cdots x_n \mapsto \lambda_i(t_n), x_{n+1} \mapsto \lambda'(x)]$
  - $\kappa'$ the set $\kappa \cup \bigcup_{y \in Res(\rho)} \{(Prog(y, \rho), (\lambda_i(t_1), \cdots, \lambda_i(t_n)), \lambda'(y))\}$

Elements of $SE(tr, \eta)$ are called symbolic transitions. We denote $Fr(\eta')$ the set of all fresh variables of $\mathcal{F}_r$ occurring in its definition.
In order to illustrate Definition 6, let us consider a transition \( tr \) of the form \((q, \psi, c.x, \rho, q')\) with \( \rho = [y \mapsto p_1(t_1, t_2), z \mapsto t'_1 + t'_2] \) with \( p_1 \) a program and \( t_1, t_2, t'_1, t'_2 \) functional terms. Let us observe that \( \text{Res}(p_1, \rho) = \{y\}, \text{Arg}(y, p_1) = (t_1, t_2), \text{Prog}(y, \rho) = p_1 \) and \( \text{Res}(\rho) = \{y\} \).

Let \( \eta = (q, \pi, \lambda, \kappa) \) be a symbolic state. Let us suppose that the program \( p_1 \) is provided with an interface \((x_1, x_2, x_3)\) and with a behavior \((\text{Pre}_1, \text{Post}_1)\). Then \( \text{SE}(tr, \eta) \) contains the symbolic transition \((q, c!f_1, q')\) with \( f_1 \) a fresh variable of \( Fr \) and \( \eta' \) the symbolic state defined as:

\[
\begin{align*}
\pi &\land (\lambda(\psi) \land (\text{Pre}_1 \land \text{Post}_1))[x_1 \mapsto \lambda(x \mapsto f_1)[t_1], x_2 \mapsto \lambda(x \mapsto f_1)[t_2], x_3 \mapsto f_2] \\
&[x \mapsto f_1, y \mapsto f_2, z \mapsto \lambda(x \mapsto f_1)[t'_1 + t'_2]], \\
\kappa &\cup \{(p_1, \lambda(x \mapsto f_1)[t_1], \lambda(x \mapsto f_1)[t_2]), f_2\}
\end{align*}
\]

\( Fr(\eta') \) is then \( \{f_1, f_2\} \).

**Definition 7 (IOSTS symbolic execution).** Given an IOSTS \( \mathcal{G} \), the symbolic execution \( \text{SE}(\mathcal{G}) = (\text{Init}, ST) \) of \( \mathcal{G} \) is minimally defined by:

- \( \text{Init} = (q_0, Ax, \lambda_0) \) with \( \forall x \in A, \lambda_0(x) \in Fr \) and \( \forall x \neq y \in A, \lambda_0(x) \neq \lambda_0(y) \),
- for \( tr \in Tr \) and \( \eta \) symbolic state with \( \text{source}(tr) = q(\eta) \), \( \text{SE}(tr, \eta) \subseteq ST \),
- for any distinct \( \text{SE}(tr_1, \eta_1) \) \( \text{SE}(tr_2, \eta_2) \) that are defined, \( Fr(\text{SE}(tr_1, \eta_1)) \cap Fr(\text{SE}(tr_2, \eta_2)) = \emptyset \).

**Definition 8 (Paths and distinguished paths).** The set \( \text{Paths}(\text{SE}(\mathcal{G})) \) of paths of \( \text{SE}(\mathcal{G}) \) is the set of all sequences \( tr_1 \cdots tr_n \) with \( \forall i \in 1 \cdots n, tr_i \in ST \) such that \( \text{source}(tr_1) = \text{Init} \) and for any \( j < n, q(\text{target}(tr_j)) = q(\text{source}(tr_{j+1})) \).

For a non-empty sequence \( \delta = tr_1 \cdots tr_n \), we note \( \text{End}(\delta) = \text{target}(tr_n) \) and \( Fr(\delta) = \cup_{i \in 1 \cdots n} Fr(\text{target}(tr_i)) \). By convention, \( \text{End}(\varepsilon) = \text{Init} \) and \( Fr(\varepsilon) = \emptyset \).

Given a finite subset \( \Delta \) of \( \text{Paths}(\text{SE}(\mathcal{G})) \), \( \text{DPaths}(\Delta) \) is a set of paths \( \delta^* \) such that there exists an unique path \( \delta \) in \( \Delta \) such that \( \delta \) and \( \delta^* \) are isomorphic up to a renaming of variables of \( Fr \) and such that for two distinct paths \( \delta_1^* \) and \( \delta_2^* \) in \( \text{DPaths}(\Delta) \), \( Fr(\delta_1^*) \cap Fr(\delta_2^*) = \emptyset \).

We say that \( \text{DPaths}(\Delta) \) is a set of distinguished paths issued from \( \text{SE}(\mathcal{G}) \).

Generally speaking, a set \( \Delta \) of \( \text{Paths}(\text{SE}(\mathcal{G})) \) represents a tree whose transitions issued from the root \( \text{Init} \) can be shared by several paths of \( \Delta \) while \( \text{DPaths}(\Delta) \) consists in applying a variable renaming mechanism in order to duplicate shared transitions to completely separate paths. Distinguished paths can still share common variables, namely those in \( W \).

**Example 4.** The drink vending machine of Fig. 4 has two possible paths from \( q \) to \( q_0 \) with exactly one cycle on \( q_0 \). They share a transition with a call to program \( Price \) defined by its contract \( C_p \) as seen in Ex. 1. We thus get 4 distinguished paths shown in Fig. 5. Associated path conditions are the following:

\[
\begin{align*}
\text{pc}_1 &: B_1 = 0 \land p_1 \geq 100 \land p_1 \leq 200 \land v_1 < p_1 \land p_1 \geq 150 \land p_1 \leq 200 \\
\text{pc}_2 &: B_2 = 0 \land p_2 \geq 100 \land p_2 \leq 200 \land v_2 \geq p_2 \land p_2 \geq 150 \land p_2 \leq 200 \\
\text{pc}_3 &: B_3 = 1 \land p_2 \geq 200 \land p_2 \leq 300 \land v_3 < p_3 \land p_3 \geq 150 \land p_3 \leq 200 \\
\text{pc}_4 &: B_4 = 1 \land p_4 \geq 200 \land p_4 \leq 300 \land v_4 < p_4 \land p_4 \geq 150 \land p_4 \leq 200
\end{align*}
\]
A path condition is a formula over the frozen variables built by accumulating constraints from the guards of the IOSTS transitions and from constraints of called programs contracts. The path is infeasible if its path condition is not satisfiable. In addition, this feasibility depends on the fact that if a program is called twice with the same arguments, it returns the same value (semantic condition of Definition 1). Since this is not enforced by the path condition alone, we consider another set of constraints accounting for this condition:

**Definition 9 (Feasibility of a set of paths).** Let $\mathcal{G}$ be an IOSTS over $\Gamma = (A, Ch)$ and let $\Delta^*$ be a set of distinguished paths issued from $SE(\mathcal{G})$.

For any program $p$ of interface $(x_1, \ldots, x_n, x_{n+1})$, for $(p, (t_1, \ldots, t_n), f)$ and $(p, (t'_1, \ldots, t'_n), f')$ two distinct elements of $\bigcup_{\delta^* \in \Delta^*} \kappa(End(\delta^*))$ we introduce the deterministic program condition relating to these two program calls as the formula $\phi\{f, f'\}$ defined by $\wedge_{i=1}^n t_i = t'_i \Rightarrow f = f'$.

The deterministic program condition related to $\Delta^*$ is then $\Phi_p = \bigwedge \phi\{f, f'\}$, for all $f$ and $f'$ appearing as return variable of a call of $p$ in $\Delta^*$.

Finally, the feasibility condition of $\Delta^*$ is

$$
\bigwedge_{\delta^* \in \Delta^*} \pi(End(\delta^*)) \land \bigwedge_{p \in P} \Phi_p
$$

If this feasibility condition holds, it is possible to implement the programs occurring in the IOSTS so that all paths of $\Delta^*$ will complete successfully. Note that the contracts of the programs are taken into account in the path condition, and have thus an impact on the paths that are feasible or not.

**Example 5.** In the context of the drink vending machine, we now want to check the feasibility condition of the distinguished paths associated to the paths described in Ex. 4 according to two distinct contracts for Price, denoted resp. $C_w$ and $C_r$ (in Example 1). Both $C_w$ and $C_r$ include two behaviors resulting in 4 distinguished paths. Path conditions are given in Tab. 2.

- With the contract $C_w$, no distinguished path is feasible because of contradictions between guards of the IOSTS transitions and post-conditions of $C_w$.
- With the contract $C_r$, all distinguished paths are feasible. Price can return anything between 150 and 200 for an argument equal to 0 and must return 200 for an argument equal to 1.

6 Testing

6.1 Model-based testing of IOSTS with program calls and contracts

In a previous work [10], we have proposed an online testing algorithm to test Systems Under Test (SUT) with respect to a basic IOSTS (without program calls). The algorithm is based on the iaco conformance relation [20] and on the use of test purposes (TP) to select some behaviors to be tested. A TP is a finite sub-tree of the symbolic execution structure (SES) derived from the IOSTS of reference so that any execution trace constructed by interacting with SUT and leading to a leaf of TP will be considered as covering TP. The testing process is implemented as a simultaneous traversal of both SES and TP. Verdicts depend on whether the observed execution trace does or does not belong to TP and SES: WeakPASS when the execution trace covers TP and belongs to at least one path of SES which does not end at a leaf of TP, PASS when the execution trace covers TP and does not belong to another path of SES, INCONC (for inconclusive) when the execution trace belongs to SES but does not cover TP, FAIL when the execution trace does not cover TP and goes outside SES.

In Section 5, we have associated to any IOSTS with contracts a symbolic tree structure in order to be able to use it both as the SES input of the algorithm given in [10] and as a carrier to extract a finite sub-tree to play the role of TP. We can use the work described in [10] with the following slight modifications:

- Unlike [10], we allow unobservable $\tau$ transitions. Under the assumption that there does not exist a cycle of $\tau$ transitions, we can replace any sequence of consecutive $\tau$ transitions by a transition carrying the input/output action just located at the end of the $\tau$ sequence. Furthermore, in [10], quiescence
conditions are expressed by enriching the reference IOSTS with transitions carrying the special label $\delta$ denoting the intended absence of reaction. Because the presence of $\tau$ transitions makes such a direct enrichment tricky, it becomes more appropriate to perform this enrichment at the level of the $\tau$-reduced symbolic execution itself. Once the operations of $\tau$-reduction and $\delta$-enrichment are applied to the symbolic execution of the IOSTS with contracts, we can then apply the algorithm of [10] for free.

– In [10], path conditions for paths that are part of test purposes are satisfiable by construction. In our setting, we have to take into account the notion of feasibility, i.e., the existence or not of programs that meet their associated contracts and that are compatible with considered paths. Indeed, if the considered set of distinguished paths constituting the test purpose is unfeasible, then the application of algorithm is meaningless. In other words, the feasibility of the targeted set of paths plays the role of a testing hypothesis.

6.2 Contracts Inference

As we have seen in Section 5, the feasibility condition checks whether a given program contract preserves the feasibility of a symbolic path or not. In this section, we focus on the inference of contracts based on path conditions. Such contracts can then be used to define unit tests for the programs. More precisely, we start with an IOSTS $G$ calling programs without associated contract. We then show that we can infer contracts such that feasible paths of $G$ are guaranteed to verify the feasibility condition of the IOSTS augmented with contracts. The generated contract for a program $p$ contains one behavior per call to $p$ in $SE(G)$. For that, we use the parts of the final condition of the path on which the call occurs that are related to the return variable and to the arguments.

Given a formula $F$, we define inductively the set $\text{Rel}_F(X)$ of variables related to a set $X$ of variables, as the smallest set satisfying the following conditions

- $X \subseteq \text{Rel}_F(X)$
- $\text{Occ}(t_1 = t_2) \cap \text{Rel}_{t_1=t_2}(X) \neq \emptyset \Rightarrow \text{Occ}(t_1 = t_2) \subset \text{Rel}_{t_1=t_2}(X)$
- $\text{Rel}_{F_1}(X) \cup \text{Rel}_{F_2}(X) = \text{Rel}_{F_1 \land F_2}(X) = \text{Rel}_{F_1 \lor F_2}(X)$
- $\text{Rel}_F(X) = \text{Rel}_{\neg F}(X)$

Similarly, for a formula $F$ and a set of variables $X$, $\text{Clean}_X(F)$ is defined as follows. As noted in remark [4] we can assume that the path condition only has conjunctions, and is in negation-normal form.

- $\text{Clean}_X(\top) = \top$
- $\text{Clean}_X(\bot) = \bot$
- $\text{Clean}_X(t_1 = t_2) = t_1 = t_2$ if $\text{Occ}(t_1 = t_2) \cap X \neq \emptyset$
- $\text{Clean}_X(t_1 = t_2) = \top$ if $\text{Occ}(t_1 = t_2) \cap X = \emptyset$
- $\text{Clean}_X(\neg t_1 = t_2) = \neg t_1 = t_2$ if $\text{Occ}(t_1 = t_2) \cap X \neq \emptyset$
- $\text{Clean}_X(\neg t_1 = t_2) = \top$ if $\text{Occ}(t_1 = t_2) \cap X = \emptyset$
- $\text{Clean}_X(F_1 \land F_2) = \text{Clean}_X(F_1) \land \text{Clean}_X(F_2)$
Remark 2. If $F$ is satisfiable, then $Clean_X(F)$ is also satisfiable, as we only remove atomic propositions from the conjunction.

**Definition 10 (Contract inference).** Let $\mathbb{G}$ be an IOSTS, $\Delta^*$ a set of distinguished paths from $SE(\mathbb{G})$. We note $\kappa(\Delta^*) = \cup_{f \in \Delta^*} \kappa(End(\delta^*))$.

For any $f$ such that $(p, (t_1, \cdots, t_n), f) \in \kappa(\Delta^*)$, with $In(p) = (x_1, \ldots, x_n)$ and $Out(p) = x_{n+1}$, we define a behavior $(Pre_f, Post_f)$ for $p$, as well as a set of frozen variables $G_f$ and axioms $Ax_f$.

We pose $\phi = \pi(End(\delta^*))$ the final condition for the path containing the call and $Y = \text{Occ}(t_1, \cdots, t_n) \cup \{f\}$ the variables occurring in the call. Then

- $G_f$ is $\text{Rel}_\phi(Y)$
- $Ax_f$ is $\text{CleanRel}_\phi(Y)(\phi)$
- $Pre_f$ is $\bigwedge_{i=1}^{n} x_i = t_i$
- $Post_f$ is $x_{n+1} = f$

Finally, the inferred contracts for $\Delta^*$ are defined as follows.

- $G$ is $\cup_{(p, (t_1, \cdots, t_n), f) \in \kappa(\Delta^*)} G_f$
- $Ax$ is $\bigwedge_{(p, (t_1, \cdots, t_n), f) \in \kappa(\Delta^*)} Ax_f$
- $\forall p \in P, C_p = ((Pre_f, Post_f))_{(p, (t_1, \cdots, t_n), f) \in \kappa(\Delta^*)}$

**Example 6.** Let us consider here a symbolic path $\delta^*$ of our drink vending machine’s specification (Figure 5) that calls twice the program $\text{Price}$ of interface $(x_1, x_2)$. The first call leads to the appearance of a message "Add" on the screen and the second call permits the drink delivery, such that: $\pi(End(\delta^*)) : v_1 < p_1 \land p_1 \geq 150 \land p_1 \leq 200 \land (v_1 + v_2) \geq p_2 \land p_2 \geq 150 \land p_2 \leq 200$

![Fig. 3: Symbolic path.](image)

From the path condition $\phi = \pi(End(\delta^*))$, two behaviors will be generated according to Def. 10. For $p_1$ the result of the first call $(\text{Price}, (B_1), p_1)$ we have:

- $Y = \{B_1, p_1\}$
- $G_{p_1} = \{B_1, p_1, v_1, p_2, v_2\}$
- $Ax_{p_1} : v_1 < p_1 \land p_1 \geq 150 \land p_1 \leq 200 \land (v_1 + v_2) \geq p_2 \land p_2 \geq 150 \land p_2 \leq 200$
- $Pre_{p_1} : x_1 = B_1$
- $Post_{p_1} : x_2 = p_1$
For $p_2$ the result of the second call $(\text{Price}, (B_2), p_2)$ we have:

\begin{align*}
Y & : \{ B_2, p_2 \} \\
G_{p_2} & : \{ B_2, p_2, v_1, p_1, v_2 \} \\
Ax_{p_2} & : v_1 < p_1 \land p_1 \geq 150 \land p_1 \leq 200 \land (v_1 + v_2) \geq p_2 \land p_2 \geq 150 \land p_2 \leq 200 \\
Pre_{p_2} & : x_1 = B_2 \\
Post_{p_2} & : x_2 = p_2
\end{align*}

Finally, the inferred contract for our program $\text{Price}$ in $\delta^*$ is:

- $G = G_{p_1} \cup G_{p_2}$
- $Ax = Ax_{p_1} \land Ax_{p_2}$
- $C = ((Pre_{p_1}, Post_{p_1}), (Pre_{p_2}, Post_{p_2}))$

We can now define the IOSTS $\mathcal{G}'$ with the same signature and transitions than $\mathcal{G}$ and equipped with the inferred contracts for the programs in $P$. Then, for every path $\delta^*$ in $\Delta^*$ that is feasible, there exist paths $\delta^*_p$ in $\mathcal{G}'$ similar to $\delta^*$ except that the path conditions $\pi$ are augmented with axioms and behaviors. For each $(p, (t_1, \ldots, t_n), f) \in \kappa(\text{End}(\delta^*)), Ax_f$ is satisfiable by remark 2 and the behavior $(Pre_f, Post_f)$ becomes trivially true: one of the behaviors of $p$ makes the corresponding transition feasible. Since this is true for any call in $\delta^*$, there exists thus a path in $\delta^*_p$ that is feasible. This leads to the following theorem.

**Theorem 1 (Feasibility preservation).** Let $\mathcal{G}$ be an IOSTS, $\Delta^*$ a set of feasible distinguished symbolic paths of $\mathcal{G}$. $\mathcal{G}'$ is the IOSTS obtained by adding to $\mathcal{G}$ the inferred contracts of Definition 10. For any path $\delta^*$ in $\Delta^*$, there exists a symbolic path $\delta'^*$ for $\mathcal{G}'$ having the same transitions as $\delta^*$ and which is feasible.

## 7 A detailed example of a vending machine with a program call for giving the change

In this section, we consider a more realistic drink vending machine example in order to introduce a rather complex user-defined program. The program call will help us to calculate the giving of change according to the coins inserted by the user and to the machine reserve.

The machine allows the user to order a coffee or a tea and returns money. The machine accepts only three different types of coins: €0.20, €0.50 and €1.

A counter (variable $m$) is used for calculating the total amount inserted by the user in the machine. According to the drink chosen by the user, as for Example 2, the price of the selected drink is given by the program $\text{Price}$ of interface $(x_1, x_2)$ where $x_1$ is of type $\text{Drink}$, an enumerated type with two values $\{0, 1\}$ and $x_2$ is of type $\text{Integer}$. $x_1$ is the input parameter indicating the selected beverage and $x_2$ is the output parameter corresponding to its price. An example of contract for $\text{Price}$ is $C_r = \{(Pre_1, Post_1), (Pre_2, Post_2)\}$ (two behaviors both disjoint and complete), with:

- $Pre_1 : x_1 = 0, Post_1 : x_2 \geq 100 \land x_2 \leq 200$
– \( Pre_2 : \, x_1 = 1 \), \( Post_2 : \, x_2 \geq 200 \land x_2 \leq 300 \)

When the desired amount is inserted, the selected beverage will be delivered to the user. If the inserted amount is more than the beverage’s cost and if the reserve contains enough change, the drink will be delivered to the user and the extra change will be returned to him. If the reserve does not contain enough change, the inserted coins will be returned to the user and he/she will be asked to top up the amount. The inserted money is specified as an array \( C \) (has three cases \( C[0], C[1] \) and \( C[2] \)) that contains respectively the number of \( €0.20, €0.50 \) and \( €1 \) coins. More precisely, we consider four such arrays, \( C \) for storing the cumulated amount inserted by the user, \( X \) for storing the current inserted amount (that the user is likely to top up if the amount is not sufficient for covering the beverage price), \( E \) for storing the giving of change and \( R \) for storing the machine reserve.

If the cumulated inserted amount \( 20 \times C[0] + 50 \times C[1] + 100 \times C[2] \) is greater than the cost and the reserve has enough change, then a program \( \text{return} \) calculates the extra change to be returned to the user as an array \( (E) \). The program \( \text{return} \) of interface \((x_1, x_2, x_3, x_4)\) where

– \( x'_1 \) represents the beverage price (positive integer),
– \( x'_2 \) represents the amount (positive integer),
– \( x'_3 \) represents the reserve (as an array storing separately the number of \( €0.20, €0.50 \) and \( €1 \) coins),
– and \( x'_4 \) is the program output variable (an array that contains the number of different coins to be returned to the user).

We associate with the \( \text{return} \) program a contract: \((Pre, Post)\) such that:

- \( Pre: \, x'_1 > 0 \land x'_2 \geq x'_1 \)
- \( Post: \, ((x'_4[0] \times 20 + x'_4[1] \times 50 + x'_4[2] \times 100) = x'_2 - x'_1) \land x'_4[0] \leq x'_3[0] \land x'_4[1] \leq x'_3[1] \land x'_4[2] \leq x'_3[2]). \)

The contract specifies that under the conditions that the beverage price \( (x'_1) \) is strictly positive and that the cumulated inserted amount \( (x'_2) \) is greater than the beverage price \( (x'_1) \), then the amount \( (x'_4[0] \times 20 + x'_4[1] \times 50 + x'_4[2] \times 100) \) represented by the output variable \( (x'_4) \) is equal to the difference \( (x'_2 - x'_1) \) and the array variable \( (x'_4) \) is less than or equal to the reserve, component by component.

Let us notice than the considered contract cannot be achieved in any situation: in particular, if the difference is equal to 20 and if \( x'_4[0] \) is equal to 0, there is no way to give back an array \( x'_4 \) making the postcondition true.

The machine’s behavior is specified by the IOSTS in Figure 4. An initialization step \((q \rightarrow q_0)\) sets \( C \) cases and the amount \( m \) to zero. Then, in state \( q_0 \), the machine waits for coins \( (X) \) introduced by the user, updates \( C \) and the amount \( m \). The user then chooses his/her beverage (0 or 1 for "Tea" or "Coffee"). The choice is stored in the variable \( B \). In the transition \( q_2 \rightarrow q_3 \), the program \( \text{Price} \) of interface \((x_1, x_2)\) computes the price of the chosen drink. Four cases are possible here:
If the introduced amount is lower than the price ($m < p$), then a message "Add" appears on the screen and the machine returns to $q_0$;
- if the user has introduced exactly an amount equal to the price ($m = p$), the drink is delivered, the reserve is updated, the amount and $C$ cases are reinitialized to zero and the machine goes back to $q_0$;
- if the user has introduced an amount strictly greater than the beverage price and if the reserve has enough change ($m > p \land \phi$), then the program Return calculates the extra change to be returned to the user and the machine goes to the state $q_4$ in order to return extra coins, set up the reserve and initialize $m$ and $C$. The formula $\phi$ defined as:

$$\exists n_1, n_2, n_3, 0 \leq n_1 \leq R[0] \land 0 \leq n_2 \leq R[1] \land 0 \leq n_3 \leq R[2] \land$$

$$m - p = n_1 \times 20 + n_2 \times 50 + n_3 \times 100$$

specifies that with the current reserve ($R$), there is at least a possibility of giving the expected change ($m - p$).
– otherwise (the user has introduced an amount strictly greater than the beverage price and the reserve does not permit to return back the extra to the user \((m > p \land \neg \phi)\)), the user is asked to refill the machine (if possible, with the exact amount) and from the state \(q_5\), the introduced coins are returned to the user.

Note that to be triggered, guards on transitions outgoing from \(q_3\) to \(q_4\) and \(q_5\) contain the \(\phi\) formula that checks the reserve’s availability. The \(\phi\) formula expresses that there is at least a combination of coins among the coin reserve that permits to give back to the user a correct change. Note also that the \(\phi\) formula is stronger than the postcondition \(\text{Post}\) previously associated to the program \(\text{Return}\); in particular, \(\phi\) makes explicit that giving change is possible, without explaining how it is calculated.

### 7.1 Symbolic execution: distinguished paths

The drink vending machine of Figure 4 has 4 possible paths from the state \(q\) to state \(q_0\) with exactly one cycle on \(q_0\), with a common transition \((q_0 \rightarrow q_1)\) including a call to the program \(\text{Price}\) defined by its contract \(C_r\) that has two behaviors (coffee or tea). The symbolic execution of the \(\text{IOSTS}\) gives rise to a set of 8 distinguished paths. They are shown in Figure 5, taken into account the renaming mechanism ensuring that fresh variables occurring in two distinct paths are distinct.

Fig. 5: Symbolic paths.
The associated path conditions are the following:

\[ pc_1 : b_1 = 0 \land p_1 \geq 100 \land p_1 \leq 200 \land m_1 < p_1 \land p_1 \geq 150 \land p_1 \leq 200 \]
\[ pc_2 : b_2 = 0 \land p_2 \geq 100 \land p_2 \leq 200 \land m_2 = p_2 \land p_2 \geq 150 \land p_2 \leq 200 \]
\[ pc_3 : b_3 = 1 \land p_3 \geq 200 \land p_3 \leq 300 \land m_3 < p_3 \land p_3 \geq 150 \land p_3 \leq 200 \]
\[ pc_4 : b_4 = 1 \land p_4 \geq 200 \land p_4 \leq 300 \land m_4 = p_4 \land p_4 \geq 150 \land p_4 \leq 200 \]
\[ pc_5 : b_5 = 0 \land p_5 \geq 100 \land p_5 \leq 200 \land m_5 > p_5 \land \neg(\exists m_1, n_2, n_3/ 0 \leq n_1 \leq r_5[0]) \]
\[ \land 0 \leq n_2 \leq r_5[1] \land 0 \leq n_3 \leq r_5[2] \land m_5 - p_5 = n_1 * 20 + n_2 * 50 + n_3 * 100 \]
\[ \land p_5 \geq 150 \land p_5 \leq 200 \]
\[ pc_6 : b_6 = 0 \land p_6 \geq 100 \land p_6 \leq 200 \land m_6 > p_6 \land \exists n_1, n_2, n_3/ 0 \leq n_1 \leq r_6[0] \]
\[ \land 0 \leq n_2 \leq r_6[1] \land 0 \leq n_3 \leq r_6[2] \land m_6 - p_6 = n_1 * 20 + n_2 * 50 + n_3 * 100 \]
\[ \land p_6 \geq 0 \land m_6 > p_6 \land ((e_1[0] * 20 + e_1[1] * 50 + e_1[2] * 100) = m_6 - p_6) \]
\[ \land e_1[0] \geq r_6[0] \land e_1[1] \geq r_6[1] \land e_1[2] \geq r_6[2] \land p_6 \geq 150 \land p_6 \leq 200 \]
\[ pc_7 : b_7 = 1 \land p_7 \geq 200 \land p_7 \leq 300 \land m_7 > p_7 \land \neg(\exists m_1, n_2, n_3/ 0 \leq n_1 \leq r_7[0]) \]
\[ \land 0 \leq n_2 \leq r_7[1] \land 0 \leq n_3 \leq r_7[2] \land m_7 - p_7 = n_1 * 20 + n_2 * 50 + n_3 * 100 \]
\[ \land p_7 \geq 150 \land p_7 \leq 200 \]
\[ pc_8 : b_8 = 1 \land p_8 \geq 200 \land p_8 \leq 300 \land m_8 > p_8 \land \exists n_1, n_2, n_3/ 0 \leq n_1 \leq r_8[0] \]
\[ \land 0 \leq n_2 \leq r_8[1] \land 0 \leq n_3 \leq r_8[2] \land m_8 - p_8 = n_1 * 20 + n_2 * 50 + n_3 * 100 \]
\[ \land p_8 \geq 0 \land m_8 > p_8 \land ((e_2[0] * 20 + e_2[1] * 50 + e_2[2] * 100) = m_8 - p_8) \]
\[ \land e_2[0] \geq r_8[0] \land e_2[1] \geq r_8[1] \land e_2[2] \geq r_8[2] \land p_8 \geq 150 \land p_8 \leq 200 \]

The four path conditions (from \( pc_1 \) to \( pc_4 \)) are associated with paths when the inserted amount is lower than the price and when the introduced amount equal to the price (for different choices of drink: coffee or tea). \( pc_5 \) and \( pc_7 \) are associated with symbolic paths issued from the numeric path where the reserve is not enough to return change. \( pc_6 \) and \( pc_8 \) are resulted from the symbolic execution of the path that contain the program \( \text{Return} \).

### 7.2 Feasibility

In the context of the drink vending machine, we now want to check the feasibility condition of a set of distinguished paths \( \Delta^* \) having \{\( pc_1, pc_2, pc_3, pc_4 \)\} as path conditions, the first four paths described in Figure 5 according to two distinct contracts for \( \text{Price} \), denoted respectively \( C_w \) and \( C_r \) and already discussed in Example 5. Both \( C_w \) and \( C_r \) include two behaviors resulting in 4 distinguished paths. Path conditions and the feasibility decision are given in Tab. 2.

- With the contract \( C_w \), no distinguished path of \( \Delta^* \) is feasible because of contradictions between guards of the IOSTS transitions and post-conditions of \( C_w \).
- With the contract \( C_r \), all distinguished paths are feasible. \( \text{Price} \) can return anything between 150 and 200 for an argument equal to 0 and must return 200 for an argument equal to 1.

### 7.3 Contract Inference

Let us consider here a symbolic path \( \delta^* \) of our drink vending machine’s specification (Figure 6) that calls twice the program \( \text{Price} \) of interface \( (x_1, x_2) \) and the program \( \text{Return} \) of interface \( (x_1', x_2', x_3', x_4') \) without associating contracts with programs. The first call of \( \text{Price} \) leads to the appearance of a message "Add" on the screen and the second call permits the drink delivery and the return of the extra, such that:
In fact, Definition 10, and in particular the function Clean, should be adapted to take into account the case of quantifier in formulas.
the program call \((\text{Return}, (p_2, m_1 + m_2, r), e_1)\) we have:

\[
Y = \{p_2, m_1 + m_2, r, e_1\}
\]

\[
G_{e_1} = \{e_1, m_1, m_2, p_2, r, p_1\}
\]

\[
\text{Ax}_{e_1} = \{m_1 < p_1 \land p_1 \geq 150 \land p_1 \leq 200 \land (m_1 + m_2) > p_2 \land p_2 \geq 150 \land p_2 \leq 200 \land \exists n_1, n_2, n_3, 0 \leq n_1 \leq r[0] \land 0 \leq n_2 \leq r[1] \land 0 \leq n_3 \leq r[2] \land (m_1 + m_2) - p_2 = n_1 + 20 + n_2 * 50 + n_3 * 100 \land ((e_1[0] * 20 + e_1[1] * 50 + e_1[2] * 100) = (m_1 + m_2) - p_2)\}
\]

\[
\text{Pre}_{e_1} : x_1 = p_2 \land x_2 = m_1 + m_2 \land x_3 = r
\]

\[
\text{Post}_{e_1} : x_4 = e_1
\]

The inferred contract for our program \(\text{Return}\) in \(\delta^*\) is \(C = (\text{Pre}_{e_1}, \text{Post}_{e_1})\).

In the same way, from \(\phi = \pi(\text{End}(\delta^*))\), two behaviors (a behavior par call) will be generated for the \(\text{Price}\) program according to our inference Definition. For \(p_1\) the result of the first call \((\text{Price}, (b_1), p_1)\) we have:

\[
Y = \{b_1, p_1\}
\]

\[
G_{p_1} = \{b_1, p_1, m_1, m_2, r, e_1\}
\]

\[
\text{Ax}_{p_1} = \{m_1 < p_1 \land p_1 \geq 150 \land p_1 \leq 200 \land (m_1 + m_2) > p_2 \land p_2 \geq 150 \land p_2 \leq 200 \land \exists n_1, n_2, n_3, 0 \leq n_1 \leq r[0] \land 0 \leq n_2 \leq r[1] \land 0 \leq n_3 \leq r[2] \land (m_1 + m_2) - p_2 = n_1 + 20 + n_2 * 50 + n_3 * 100 \land ((e_1[0] * 20 + e_1[1] * 50 + e_1[2] * 100) = (m_1 + m_2) - p_2)\}
\]

\[
\text{Pre}_{p_1} : x_1 = b_1
\]

\[
\text{Post}_{p_1} : x_2 = p_1
\]

For \(p_2\) the result of the second call \((\text{Price}, (b_2), p_2)\) we have:

\[
Y = \{b_2, p_2\}
\]

\[
G_{p_2} = \{b_2, p_2, m_1, p_1, m_2, r, e_1\}
\]

\[
\text{Ax}_{p_2} = \{m_1 < p_1 \land p_1 \geq 150 \land p_1 \leq 200 \land (m_1 + m_2) > p_2 \land p_2 \geq 150 \land p_2 \leq 200 \land \exists n_1, n_2, n_3, 0 \leq n_1 \leq r[0] \land 0 \leq n_2 \leq r[1] \land 0 \leq n_3 \leq r[2] \land (m_1 + m_2) - p_2 = n_1 + 20 + n_2 * 50 + n_3 * 100 \land ((e_1[0] * 20 + e_1[1] * 50 + e_1[2] * 100) = (m_1 + m_2) - p_2)\}
\]

\[
\text{Pre}_{p_2} : x_1 = b_2
\]

\[
\text{Post}_{p_2} : x_2 = p_2
\]

Finally, the inferred contract for our program \(\text{Price}\) in \(\delta^*\) is:

\[
- G = G_{p_1} \cup G_{p_2}
- \text{Ax} = \text{Ax}_{p_1} \land \text{Ax}_{p_2}
- C = ((\text{Pre}_{p_1}, \text{Post}_{p_1}), (\text{Pre}_{p_2}, \text{Post}_{p_2}))
\]

8 Related Work

In the context of reactive systems verification, IOSTS and symbolic execution have been used in many works \([10,13]\) for different purposes. They use IOSTS with atomic actions and substitutions whereas, in our case, we enrich IOSTS with programs specified by contracts. Our purpose is to define an integration framework and analyze in one hand the impact of programs contracts on a whole system and in the other hand elicit accurate contracts for our programs.
Our work is quite close to [12], that augments a SOA’s BPEL business model with pre- and post-condition contracts defining essential component traits, and derive a suite of feasible test cases, taking into account contracts that are provided for some of the opaque components of their system. On the other hand, they do not infer contracts from the constraints expressed directly in the BPEL model as is done in section 6.2.

The use of symbolic execution and path feasibility analysis are studied in [3,21] but this is limited to the analysis of programs themselves and does not take in consideration as we do the impact of the program calls on the feasibility of the system as a whole. Similarly, symbolic execution techniques over the code have been used to infer program annotations. More specifically, such approaches concentrate on generating invariants. This is for instance the case in the KeY verification framework [19], for the DySy tool [6], or for the iDiscovery tool [23]. Those invariants are meant to help the formal verification of the code against its specification, while we are aiming at generating a specification that the programs must meet in order to be usable in the context of the system under test.

The problem of inferring contracts for programs has been studied differently in other works that do not rely on symbolic execution. In particular, [5] derives pre-conditions from assertions already present in the code using abstract interpretation. [22] uses dynamic analysis to augment simple programmer-written contracts with candidate post-conditions that describes precisely what the code is doing, building upon techniques developed initially in the Daikon tool [8] for proposing likely invariants. This kind of inference is dual to ours, in the sense that we infer contracts in a top-down approach, in order to express what conditions individual components should fulfill inside a broader system, while the works mentioned above are bottom-up, encapsulating the behavior of actual code in contracts in order to check whether callers can use this particular implementation. The same can be said of works that aim at generating transition systems modeling the behavior of programs, either as message sequence charts as in [15], or as scenarios expressed under the form of live sequence charts, as in [16].

9 Conclusion

In this work, we extended the IOSTS framework with programs which are specified with contracts and we adapted symbolic execution techniques to deal with them. This gives rise to two main results. First, we study how contracts impact path conditions and describe the feasibility condition of the entire symbolic execution tree. Second, we show that path conditions can be used to infer contracts for programs in order to specify what these programs should do in the context of the system under test. Such contracts can then be used for unitary testing purposes, while feasibility preservation theorem gives some guarantees that program calls will not get in the way during integration testing. Implementation of the technique presented in this paper is currently under development in the Diversity [7] symbolic execution tool and the Frama-C [14] C code analysis framework using the ACSL specification language [2] as target for contract inference.

Future work include in particular integrating programs and contracts into various IOSTS extensions. From an implementation point of view, UML Sequence Diagrams [18], a widely used formalism for describing transition systems, would be a good input language from a practical point of view. Sequence diagrams are already supported by Diversity, but program calls and contracts need to be added to the UML
subset supported by Diversity. On a more theoretical level, we have so far examined program and contracts in one single component. IOSTS are nevertheless meant to model whole systems consisting in various components interacting with each other through communication actions. Path conditions can then be projected on the internal state of a single component to define constraints on this component. It would be interesting to examine how to compose such projections with contract inference.
