HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
High resolution solid state NMR has become an extremely useful tool for the structural characterization of a large variety of materials ranging from inorganic to porous materials, zeolites, hybrid organic-inorganic, organic and bio-involved materials. This is due to the ability of NMR to characterize ordered crystalline structures, but also to give detailed insight to the structure of partly disorganized, amorphous or glassy materials. An important part of the power of solid state NMR methods comes from their ability to produce homo-nuclear or hetero-nuclear correlation charts that can evidence spatial proximity (from dipolar interaction) or chemical bonding (from J-couplings), as used to derive protein structures in liquid state. Nevertheless a major difficulty arises with quadrupolar nuclei (nuclear spin $I>1/2$) because the quadrupolar interaction induces quick relaxation in liquid state, and broadening at first and second order in solids. The quadrupolar nuclei are the most abundant nuclei in inorganic materials and of crucial importance in many biological structures. The question of efficiently generating a correlation between quadrupolar nuclei under high resolution conditions (fast Magic Angle Spinning – MAS and high magnetic fields) remained an open question. In this contribution we show that such a correlation experiment can be generated with a simple and robust pulse sequence, using an isotropic (or scalar) interaction that does not necessitate re-introduction by sophisticated spin manipulation. We demonstrate the experiment with a $^{17}$O-$^{27}$Al (both $I=5/2$ nuclei) experiment carried out on a crystalline test sample and show that the technique is reliable and sensitive enough to unambiguously demonstrate the experiment with a $^{17}$O $^{27}$Al (both $I=5/2$ nuclei) experiment. The robustness of the sequence comes from the minimum number of pulses involved on both channels, and to difficulties in obtaining homogeneous irradiation of the whole spectrum. The HMQC experiment is run synchronized with the MAS spinning rate so that possible spinning sidebands sum up in the indirect dimension. Our experiments were acquired at high principal field (750 MHz – $B_0$ 17.6 T) which reduces second order quadrupolar broadenings and increases sensitivity, with a gain proportional to $B_0^2$ for each dimension, and to $B_0^4$ for the correlation experiment. The signal to noise of the whole experiment is optimized by several signal enhancement methods: Double Frequency Sweep (DFS) on the starting nucleus (gain $> 20$), acquisition and processing of the full echo (gain $> \sqrt{2}$). If we assume that the scalar J-coupling is the active interaction, the double quantum filtered signal grows with $\sin(\pi J \tau) / (\pi J \tau + 1/2)$, and competes with the $T_2^*$ exponential decay. The $T_2^*$ of half integer quadrupolar nuclei can be significantly increased when spinning slightly off the magic angle. For our test sample (CA2), figure 2a shows that $T_2^*$ gets nearly twice as long, with a signal enhancement of ~3, when running the HMQC experiment off the magic angle by ~1°. Under
these conditions, the dipolar interaction partially remains (off magic angle contribution) and may participate in the correlation. We can remark that this angle offset remains small enough to enhance the signal without broadening the lineshapes of both nuclei. Moreover, because both nuclei undergo second order broadening, the $^{17}$O$^{27}$Al correlation chart contains the encoding of their relative spatial orientation.

The structure of Grossite (CA$_2$-CaAl$_2$O$_5$) crystalline phase involves 4 different $^{27}$Al sites$^{2}$; three with the usual $\mu_2$ coordination, OAl$_1$ (O1, O2, O3) and one with a unique example, in a crystalline compound of that family, of a “tricluuster” $\mu_3$ coordination : OAl$_1$ (O4). Aluminum occupies two different $\{\mu_2\}$_4(\mu_3)$_1$ sites : Al-1 (x=1) and Al-2 (x=2) with different $^{27}$Al chemical shifts and quadrupolar couplings$^{25}$. The connectivity scheme is unambiguously established from the $^{17}$O$^{27}$Al HMQC correlation spectrum (figure 3): Al-1 is connected with O4, O3 and 2xO2 whereas Al-2 is connected with 2xO4, O3 and O1. Summarizing the NMR parameters of the CA$_2$ and Ca(CaAl$_3$O$_7$) crystals (supp. inf.) we remark that the $^{27}$Al isotropic chemical shift of Al(\mu$_2$)$_4$ is -1.5 ppm, Al(\mu$_2$)$_3$(\mu$_3$)$_1$ 2.0 ppm and Al(\mu$_2$)$_4$ 4.0 ppm.

In conclusion, we showed for the first time that it is possible to acquire efficiently heteronuclear correlation experiments in solid state between second order broadened half integer quadrupolar nuclei using isotopic mixing, presumably mediated by a scalar J-coupling that remains largely unknown. This experiment is possible thanks to the gain of sensitivity proportional to the fourth power of the principal field that turns a challenging experiment to a real efficient tool. This class of experiment could be extended to other pairs of nuclei. We believe that it may become very useful, providing detailed insight to the structure and properties of glasses, porous or mesoporous framework materials, zeolites, hybrid organic-inorganic or even bio-involved materials, addressing questions like the characterization of oxygen protonation state or activity of catalytic materials.

Acknowledgements: We acknowledge financial support from CNRS UPR4212, Région Centre, CNRS (CM) and “Le Studium” fellowships (DI).

Supporting informations: Acquisition parameters, $^{27}$Al and $^{17}$O NMR parameters of the CA and CA$2$ crystals, and CA-glass.

**Figure 2** : $^{17}$O $30\%$ enriched CA$_2$-CA$_3$O$_7$ crystalline sample: a) variation of $T_2'$ for the two Al sites and HMQC intensity (normalized to on angle) versus angle offset from MAS. b) $^{17}$O$^{27}$Al HMQC spectrum (v$_c$ 15kHz, $\tau$ 3ms, 17.6 T-750 MHz, 64 scans).

**Figure 3** : $^{17}$O$^{27}$Al HMQC spectrum (v$_c$ 25kHz, $\tau$ 7ms, 17.6T, 480 scans) of CA-glass ($^{17}$O $30\%$ enriched) and $^{27}$Al-slices taken at $\mu_2$ and $\mu_3$ locations, exhibiting a 5 ppm difference in the isotropic chemical shift. The dotted lines are the modelled lines considering a GIM distribution$^{2}$. The dashed lines indicate the position of $^{27}$Al isotropic chemical shifts.

Given the robustness of the sequence, and its remarkable sensitivity (only 64 transients for the CA$_2$ experiment), it was possible to acquire a spectrum of a ground droplet of ~50mg of a CA (CaO-Al$_2$O$_3$) glass sample obtained with a contactless laser heated aerodynamic levitation device$^{2}$. The $^{17}$O and $^{27}$Al individual MAS and MQMAS spectra of CA glass already provide information. The distribution of isotropic chemical shifts dominates the $^{17}$O spectra with small second order effects$^{2}$. They show a main line extending from -90 down to ~30 ppm, clearly suggesting two Gaussian components at 69 and 37 ppm. This 37 ppm component, absent in Ca rich CA38 glass$^{2}$, is located at the expected $\mu_3$ position. The distributions of both isotropic chemical shifts and quadrupolar interaction dominate the $^{27}$Al dimension inducing typical asymmetric line shapes (with $\delta_{iso}$ in its rising left edge) that can be reliably modeled using a Gaussian Isotropic Model (GIM)$^{2}$. The $^{17}$O$^{27}$Al HMQC correlation spectrum (figure 3) confirms the presence of two bridging oxygen components ($\mu_2$ and ~5% $\mu_3$) with their relevant aluminum counterparts Al(\mu$_2$)$_4$, Al(\mu$_2$)$_3$(\mu$_3$)$_1$, unambiguously identified from their isotropic chemical shifts (79 and 74 ppm). This result is the first comprehensive experimental proof of the presence of $\mu_3$ oxygen sites$^{22,25-27}$, both from their O and Al signature.

---

We show for the first time that it is possible to acquire high resolution heteronuclear NMR correlation experiments in solid state between second order broadened half integer quadrupolar nuclei (i.e. $^{27}\text{Al}$ and $^{17}\text{O}$) using the scalar J-coupling. The sensitivity of the experiment is dramatically improved at high fields (gain proportional to the fourth power of the principal field) with a combination of signal enhancement techniques. This turns a challenging experiment to a real tool. We apply this experiment to characterize a Calcium Aluminate glass in which we prove the presence of tricluster $\mu_3$ Oxygen sites and describe the signature of their directly bonded Aluminum sites. Applications involve a large range of possible pairs of quadrupolar nuclei in different materials like glasses, porous or mesoporous framework materials, zeolites, hybrid organic-inorganic, and bio-involved materials.
