DYNAMICS ON RESONANT CLUSTERS FOR THE QUINTIC NONLINEAR SCHRÖDINGER EQUATION

by

Emanuele Haus & Laurent Thomann

Abstract. — We construct solutions to the quintic nonlinear Schrödinger equation on the circle
\[ i\partial_t u + \partial_x^2 u = \nu |u|^4 u, \quad \nu \ll 1, \quad x \in S^1, \quad t \in \mathbb{R}, \]
with initial conditions supported on arbitrarily many different resonant clusters. This is a sequel the work [5] of Benoît Grébert and the second author.

1. Introduction and results

1.1. General introduction. — In this paper we consider the quintic nonlinear periodic Schrödinger equation
\[
\begin{cases}
  i\partial_t u + \partial_x^2 u = \nu |u|^4 u, & (t, x) \in \mathbb{R} \times S^1, \\
  u(0, x) = u_0(x),
\end{cases}
\]
where \( \nu > 0 \) is some small parameter. In [5] B. Grébert and the second author showed a beating effect for (1.1): there exist solutions which are supported on 4 so-called resonant modes and which stay close to a time-periodic solution for long time. These solutions moreover show that there is an energy exchange between the considered modes, which is a genuine nonlinear effect. We call this mechanism a beating effect. Such a phenomenon was first observed by Grébert and Villegas-Blas [6] on a cubic Schrödinger equation. Let us also mention the work [4] by Grébert-Paturel-Thomann where a general principle is extracted so that such a phenomenon occurs. Finally we refer to the introduction of [5] for more results on the long time dynamics for (1.1) and related models.

Our aim here is to extend the main result of [5] and show that we can construct solutions to (1.1) supported on arbitrarily many resonant modes.

Recall [5] Definition 1.1] that a set of the form
\[ \{ n, n + 3k, n + 4k, n + k \}, \quad k \in \mathbb{Z} \setminus \{0\} \quad \text{and} \quad n \in \mathbb{Z}, \]

2000 Mathematics Subject Classification. — 37K45, 35Q55, 35B34, 35B35.

is called a resonant set. These sets exactly correspond to the resonant monomials of order 6 of the Hamiltonian of (1.1) which contain 4 different modes. Here, we consider resonant sets of the type

\[(1.3) \quad A_k = \{n_k - 2, n_k - 1, n_k + 1, n_k + 2\},\]

where \((n_k)_{k \geq 1}\) is a sequence of integers which will be described. In the sequel, we denote by

\[(1.4) \quad a_2^{(k)} = n_k - 2, \quad a_1^{(k)} = n_k + 1, \quad b_2^{(k)} = n_k + 2, \quad b_1^{(k)} = n_k - 1,\]

and for \(K \geq 1\), we define

\[A = \bigcup_{k=1}^{K} A_k.\]

To begin with, let us recall the result of [5] for the resonant set \(A_k\).

**Theorem 1.1 ([5]).** — Let \(k \geq 1\). There exist \(T_k > 0\), \(\nu_0 > 0\), \(\alpha_k \in (0, 1/2)\) and a \(2T_k\)-periodic function \(K_\nu^{(k)} : \mathbb{R} \to (0, 1)\) which satisfies \(K_\nu^{(k)}(0) \leq \alpha_k\) and \(K_\nu^{(k)}(T_k) \geq 1 - \alpha_k\) and if \(0 < \nu < \nu_0\), there exists a solution \(u_k\) to (1.1) satisfying for all \(|t| \leq \nu^{-9/8}\)

\[u_k(t, x) = v_k(t, x) + \nu^{1/4} q(t, x),\]

with

\[v_k(t, x) = \sum_{j \in A_k} w_j(t) e^{ijx},\]

and

\[|w_{a_1^{(k)}}(t)|^2 = 2|w_{b_2^{(k)}}(t)|^2 = K_\nu^{(k)}(\nu t),\]

\[|w_{a_2^{(k)}}(t)|^2 = 2|w_{b_1^{(k)}}(t)|^2 = 1 - K_\nu^{(k)}(\nu t),\]

and \(q\) is smooth in time and analytic in space on \([-\nu^{-9/8}, \nu^{-9/8}] \times \mathbb{S}^1\). Moreover, the Fourier coefficients \(\hat{q}_j(t)\) of \(q(t)\) satisfy

\[\sup_{|t| \leq \nu^{-9/8}} |\hat{q}_j(t)| \leq C e^{-|j|},\]

with \(C\) independent of \(k \geq 1\) and \(\nu > 0\).

The result is not exactly stated like this in [5], but is proven there. In particular, the analyticity of the remainder term follows from the analytical framework of the Birkhoff normal form procedure in [5] Section 3]. See also [4].

Theorem 1.1 shows that there are non trivial interactions between the modes in \(A_k\) and they occur for times \(t \sim \nu^{-1} T_k\).

**1.2. The main result.** — In this paper we prove that if the resonant sets are carefully chosen, there exist solutions to (1.1) which are the superposition of solutions of the previous type.

**Theorem 1.2.** — There exists \(\nu_0 > 0\) and there exists an increasing sequence of integers \((n_k)_{k \geq 1}\) such that, if \(0 < \nu < \nu_0\), for all \(K \geq 1\) with \(n_K \leq -c \ln \nu\) there exists a solution to (1.1) which reads for all \(|t| \leq \nu^{-9/8}\)

\[(1.5) \quad u(t, x) = \sum_{k=1}^{K} e^{-n_k} v_k(t, x) + \nu^{1/4} q(t, x),\]
where

i) For all \( 1 \leq k \leq K \), \( v_k \) is as in Theorem 1.1.

ii) The error term is smooth in time and analytic in space on \([-\nu^{-9/8}, \nu^{-9/8}] \times S^1\). Moreover, the Fourier coefficients \( \hat{q}_j(t) \) of \( q(t) \) satisfy

\[
\sup_{|t| \leq \nu^{-9/8}} |\hat{q}_j(t)| \leq Ce^{-|j|},
\]

with \( C \) independent of \( K \geq 1 \) and \( \nu > 0 \).

This result shows a beating effect inside of each resonant set, but there is no energy transfer between two different resonant clusters. In particular, we do not show an energy transfer from the low to the high frequencies.

In our example, for all \( s \geq 0 \), \( \|u\|_{H^s} \) is almost preserved during the time. This is due to the particular form (1.3) of our resonant sets. We believe that a similar construction for more general resonant sets (1.2) can be done.

For all \( j \in \mathbb{Z} \), the Fourier coefficient \( \hat{u}_j \) of \( u \) in (1.5) satisfies

\[
\sup_{|t| \leq \nu^{-9/8}} |\hat{u}_j(t)| \leq Ce^{-|j|},
\]

thus \( u \) is bounded in an analytic norm uniformly in \( K \geq 1 \) for this time scale. A natural question is whether we can choose \( K = +\infty \) in Theorem 1.2. Our method does not allow this extension since the period of \( v_k \) grows to infinity with \( k \). Moreover, the expansion in (1.5) is relevant as long as \( e^{-n_k v_k} \) is larger than the error term, and this gives the limitation \( n_k \leq -c \ln \nu \).

In fact there are many sequences which satisfy Theorem 1.2: almost all sequences which satisfy \( n_{k+1} \geq 12n_k^2 \) can be taken (see the proof of Proposition 2.2).

Our approach allows also to treat the focusing Schrödinger equation (\( \nu < 0 \)), but for simplicity we only deal with the case \( \nu > 0 \).

With an appropriate choice of the initial conditions, we can construct quasi-periodic solutions in time for a large set of frequencies.

**Corollary 1.3.** — For every \( K \geq 1 \) and every sequence of real numbers \( \Lambda_1, \Lambda_2, \ldots, \Lambda_K > 0 \), there exists \( N \in \mathbb{N} \) so that, if \( \nu > 0 \) is small enough, we can construct \( v_k \) of period \( 2N\Lambda_k/\nu \) in time.

This is clearly a nonlinear phenomenon, since in the linear regime all the frequencies are integer multiples of the same number.

1.3. Plan of the paper. — In Section 2 we prove the existence of resonant sets made up of several clusters which do not interact much with one another. In Section 3 we recall the Hamiltonian structure of (1.1) and we study the model equation, which is obtained by truncating the error terms of the normal form (higher order terms and terms involving frequencies outside the resonant sets). In Section 4 we perform the perturbation analysis and collect the results of the previous sections in order to prove our main results. Throughout the paper, we widely rely on the results obtained by B. Grébert and the second author in [5]: since several proofs turn out to be similar, here we choose to highlight what is new and different, rather than copy out the proofs in [5].
2. Existence of resonant sets

In this section, we show the existence of a sequence \((n_k)\) such that the modes in \(A_k\) and \(A_j\) do not interact much when \(k < j\). We will see that this is ensured when \((n_k)\) is growing fast enough and if it satisfies some arithmetical condition.

**Lemma 2.1.** — Assume that the sequence \((n_k)_{k \geq 1}\) satisfies \(n_1 \geq 3\) and \(n_{k+1} \geq 12n_k^2\). Then the following holds true: Let \(S := \{j_1, j_2, j_3, \ell_1, \ell_2, \ell_3\} \subseteq A\) with

\[
\begin{cases}
    j_1^2 + j_2^2 + j_3^2 = \ell_1^2 + \ell_2^2 + \ell_3^2, \\
    j_1 + j_2 + j_3 = \ell_1 + \ell_2 + \ell_3,
\end{cases}
\]

and \(\{j_1, j_2, j_3\} \neq \{\ell_1, \ell_2, \ell_3\}\).

Then there exists \(1 \leq k \leq K\) so that \(S \subseteq A_k\).

**Proof.** — Consider \(S = \{j_1, j_2, j_3, \ell_1, \ell_2, \ell_3\} \subseteq A\) such that \((2.1)\) holds. Assume that \(\ell_1 = \max S\). Then \(\ell_1 = n_k + r_1\) for some \(1 \leq k \leq K\) and \(r_1 \in \{-2, -1, 1, 2\}\). If \(k = 1\) we are done, hence we assume that \(k \geq 2\). We claim that one of the integers \(j_1, j_2, j_3\), say \(j_1\), is of the form \(j_1 = n_k + q_1\) with \(q_1 \in \{-2, -1, 1, 2\}\). If it is not the case, \(j_1, j_2, j_3 \leq n_{k-1} + 2\) and thus

\[
j_1^2 + j_2^2 + j_3^2 \leq 3(n_{k-1} + 2)^2 < 12n_{k-1}^2 \leq n_k \leq (n_k - 2)^2 \leq \ell_1^2,
\]

which is a contradiction. We plug the expressions of \(\ell_1\) and \(j_1\) in \((2.1)\) and obtain

\[
(2.2) \quad 2(q_1 - r_1)n_k = \ell_1^2 + \ell_1^2 + j_2^2 - j_2^2 - j_3^2 + r_1^2 - q_1^2.
\]

From \([5]\) Lemma 2.1 we have \(q_1 \neq r_1\).

- Assume that \(\{\ell_2, \ell_3, j_2, j_3\} \subset \bigcup_{m=1}^{k-1} A_m\). Then

\[
|\ell_2^2 + \ell_3^2 - j_2^2 - j_3^2 + r_1^2 - q_1^2| \leq 6(n_{k-1} + 2)^2 < 24n_{k-1}^2 \leq 2n_k \leq 2|q_1 - r_1|n_k,
\]

which is a contradiction.

- We can therefore assume that \(\ell_2 \in A_k\). If \(\{j_2, j_3\} \subset \bigcup_{m=1}^{k-1} A_m\) we can show that

\[
2(q_1 - r_1)n_k < \ell_2^2 + j_2^2 - j_3^2 + r_1^2 - q_1^2,
\]

thus we can assume that \(j_2 \in A_k\) and we write \(j_2 = n_k + q_2\), \(\ell_2 = n_k + r_2\). The relation \((2.2)\) then reads

\[
2(q_1 + q_2 - r_1 - r_2)n_k = \ell_3^2 - j_2^2 + r_1^2 + q_2^2 - q_1^2 - q_2^2.
\]

With a similar argument we deduce that \(\{\ell_3, j_3\} \subset A_k\), which completes the proof.  

Define the set

\[
\mathcal{R} = \{(j_1, j_2, j_3, \ell_1, \ell_2, \ell_3) \in \mathbb{Z}^6 \text{ s.t. } j_1 + j_2 + j_3 = \ell_1 + \ell_2 + \ell_3 \text{ and } j_1^2 + j_2^2 + j_3^2 = \ell_1^2 + \ell_2^2 + \ell_3^2\}.
\]

**Proposition 2.2.** — There exists a sequence \((n_k)_{k \geq 1}\) which satisfies \(n_1 \geq 3\), \(n_{k+1} \geq 12n_k^2\) and so that the following holds true: Let \((j_1, j_2, j_3, \ell_1, p_1, p_2) \in \mathcal{R}\). Assume that \(j_1, j_2, j_3, \ell_1 \in A\). Then \(p_1, p_2 \in A\).
Proof. — We construct such a sequence \((n_k)_{k \geq 1}\) by induction. When \(K = 1\), we can apply [5] Lemma 2.4] and set any \(n_1 \geq 3\). Now, assume that we have constructed the first \(K\) elements of the sequence \((n_k)_{k=1}^K\). We will prove that we can choose \(n_{K+1}\) satisfying the wanted properties.

Suppose that we have fixed \(n_{K+1}\) (and therefore \(\mathcal{A}_{K+1}\)): we now investigate which arithmetical properties are required in order to satisfy the non-resonance condition.

Let \(j_1, j_2, j_3, \ell_1 \in \mathcal{A}\) and \(p_1, p_2 \in \mathbb{N}\) so that

\[
\begin{cases}
p_1 + p_2 = j_1 + j_2 + j_3 - \ell_1 =: S, \\
p_1^2 + p_2^2 = j_1^2 + j_2^2 + j_3^2 - \ell_1^2 =: T.
\end{cases}
\]

The two complex (possibly coinciding) solutions \((p_1, p_2)\) to the equation are the roots of the polynomial

\[X^2 - SX + \frac{1}{2}(S^2 - T) = 0.
\]

The discriminant of this polynomial is \(\Delta = 2T - S^2\). Therefore, a necessary condition for \((p_1, p_2)\) to have integer solutions is that \(2T - S^2\) is a perfect square.

Each of the elements \(j_1, j_2, j_3, \ell_1\) may belong either to \(\mathcal{A}_{K+1}\) or to \(\mathcal{A}_k\) with \(k \leq K\). We have to distinguish 8 different cases, depending on how many of the \(j\)'s belong to \(\mathcal{A}_{K+1}\) (4 possibilities, from 0 to 3) and whether \(\ell_1 \in \mathcal{A}_{K+1}\) or not.

- **Case (0,0):** \(j_1, j_2, j_3, \ell_1 \notin \mathcal{A}_{K+1}\).
  - No further property has to be verified: the non-resonance condition is satisfied by induction hypothesis.
  - **Case (1,0):** \(j_1 \in \mathcal{A}_{K+1}, j_2, j_3, \ell_1 \notin \mathcal{A}_{K+1}\).
    - We exploit the identity
      \[
      \Delta = 2(j_1^2 + j_2^2 + j_3^2 - \ell_1^2) - (j_1 + j_2 + j_3 - \ell_1)^2 = (j_1 - j_2 - j_3 + \ell_1)^2 - 4(\ell_1 - j_2)(\ell_1 - j_3).
      \]
      Now, \(j_1\) may be expressed as \(j_1 = n_{K+1} + c_1, \) with \(c_1 \in \{-2, -1, 1, 2\}\). Therefore
      \[
      \Delta = (n_{K+1} + c_1 - j_2 - j_3 + \ell_1)^2 - 4(\ell_1 - j_2)(\ell_1 - j_3).
      \]
      The relevant thing here is that \(\Delta\) has the form \((n_{K+1} + \tilde{c}_1)^2 + \tilde{c}_2\). If \(\tilde{c}_2 = 0\), then either \(\ell_1 = j_2\) or \(\ell_1 = j_3\), which implies the non-resonance condition \(p_1, p_2 \in \mathcal{A}\), by [5] Lemma 2.1. If \(\tilde{c}_2 \neq 0\), it is sufficient to choose \(n_{K+1}\) large enough to prevent \(\Delta\) from being a perfect square.

  - **Case (2,0):** \(j_1, j_2 \in \mathcal{A}_{K+1}, j_3, \ell_1 \notin \mathcal{A}_{K+1}\).
    - We have \(j_1 = n_{K+1} + c_1, j_2 = n_{K+1} + c_2\) with \(c_1, c_2 \in \{-2, -1, 1, 2\}\). Thus,
      \[
      \Delta = 2[(n_{K+1} + c_1)^2 + (n_{K+1} + c_2)^2 + j_3^2 - \ell_1^2] - [(n_{K+1} + c_1) + (n_{K+1} + c_2) + j_3 - \ell_1]^2 = -4(j_3 - \ell_1)n_{K+1} + (c_1 - c_2)^2 - 2(c_1 + c_2)(j_3 - \ell_1) + (j_3 - \ell_1^2) = (j_3 - \ell_1)(j_3 + 3\ell_1).
      \]
      If \(\ell_1 = j_3\), then \(p_1, p_2 \in \mathcal{A}\), by [5] Lemma 2.1. If \(\ell_1 \neq j_3\), then \(\Delta\) has the form \(\alpha n_{K+1} + \beta\), with \(\alpha \neq 0\).

  - **Case (3,0):** \(j_1, j_2, j_3 \in \mathcal{A}_{K+1}, \ell_1 \notin \mathcal{A}_{K+1}\).
    - The conditions \(n_1 \geq 3, n_{k+1} \geq 12n_k^2\) imply that if \(k_1 \neq k_2\) then \(|n_{k_1} - n_{k_2}| \geq 105 = 12 \cdot 3^2 - 3\). Therefore we exploit the translation invariance of the resonance condition and we translate back \((j_1, j_2, j_3, \ell_1, p_1, p_2)\) obtaining the new resonant sextuple
      \[
      (\tilde{j}_1, \tilde{j}_2, \tilde{j}_3, \tilde{\ell}_1, \tilde{p}_1, \tilde{p}_2) := (j_1 - n_{K+1}, j_2 - n_{K+1}, j_3 - n_{K+1}, \ell_1 - n_{K+1}, p_1 - n_{K+1}, p_2 - n_{K+1})
      \]
      with \(|\tilde{j}_1|, |\tilde{j}_2|, |\tilde{j}_3| \leq 2\) and \(|\tilde{\ell}_1| \geq 105 - 2 = 103\), which is clearly absurd since
      \[
      \tilde{j}_1^2 + \tilde{j}_2^2 + \tilde{j}_3^2 = \tilde{\ell}_1^2 + \tilde{p}_1^2 + \tilde{p}_2^2.
      \]
• Case (0,1): $\ell_1 \in A_{K+1}, j_1, j_2, j_3 \notin A_{K+1}$.

This case is easily seen to be absurd, since
\[ j_1^2 + j_2^2 + j_3^2 = \ell_1^2 + p_1^2 + p_2^2 \]
and $\ell_1$ is much bigger than $j_1, j_2, j_3$.

• Case (1,1): $j_1, \ell_1 \in A_{K+1}, j_2, j_3 \notin A_{K+1}$.

We write $j_1 = n_{K+1} + c_1, \ell_1 = n_{K+1} + c_2$ with $c_1, c_2 \in \{-2, -1, 1, 2\}$. So we have
\[
\Delta = 2 \left( (n_{K+1} + c_1)^2 + j_2^2 + j_3^2 - (n_{K+1} + c_2)^2 \right) - \left( (n_{K+1} + c_1) + j_2 + j_3 - (n_{K+1} + c_2) \right)^2 = 4(c_1 - c_2)n_{K+1} + (c_1^2 + j_2^2 + j_3^2 - c_2^2) - (c_1 + j_2 + j_3 - c_2)^2.
\]

If $c_1 = c_2$, then $j_1 = \ell_1$ and $p_1, p_2 \in A$ because of \cite{5} Lemma 2.1. Otherwise, $\Delta$ has the form $an_{K+1} + \beta$, with $\alpha \neq 0$.

• Case (2,1): $j_1, j_2, \ell_1 \in A_{K+1}, j_3 \notin A_{K+1}$.

We have $j_1 = n_{K+1} + c_1, j_2 = n_{K+1} + c_2, \ell_1 = n_{K+1} + c_3$ with $c_1, c_2, c_3 \in \{-2, -1, 1, 2\}$. Therefore
\[
\Delta = 2 \left( (n_{K+1} + c_1)^2 + (n_{K+1} + c_2)^2 + j_3^2 - (n_{K+1} + c_3)^2 \right) - (n_{K+1} + c_1 + c_2 + j_3 - c_3)^2 = (n_{K+1} + c_1 + c_2 - c_3 - j_3)^2 - 4(c_1 - c_2)(c_3 - c_2),
\]
which has the same structure as for the case (1,0) and therefore $\Delta$ is not a perfect square provided that $n_{K+1}$ is large enough.

• Case (3,1): $j_1, j_2, j_3, \ell_1 \in A_{K+1}$.

Then we have directly $p_1, p_2 \in A_{K+1} \subset A$, by \cite{5} Lemma 2.4.

Now, what still has to be proved is that we can choose $n_{K+1}$ arbitrarily large and such that $\alpha, n_{K+1} + \beta$ is not a square for a finite number of couples of integers $\{(\alpha_r, \beta_r)\}_{r=1}^s$. We can limit ourselves to $\alpha_r > 0$, since the conditions to be satisfied yield $\alpha_r \neq 0$ and, if $\alpha_r < 0$, then $\alpha_r n_{K+1} + \beta$ is negative and therefore not a perfect square, for $n_{K+1}$ large enough. Let $\alpha := (\alpha_1, \ldots, \alpha_s) \in (\mathbb{N} \setminus \{0\})^s$ and $\beta := (\beta_1, \ldots, \beta_s) \in \mathbb{Z}^s$. We denote by $S_{\alpha, \beta} := \{(\alpha_r, \beta_r)\}_{r=1}^s$ the set of all couples $(\alpha_r, \beta_r)$, for a given choice of $\alpha \in (\mathbb{N} \setminus \{0\})^s$ and $\beta \in \mathbb{Z}^s$.

**Definition 1.** — We say that a positive integer $n \in \mathbb{N}$ satisfies the “no-square condition” with respect to $S_{\alpha, \beta}$ (NSC-$S_{\alpha, \beta}$) if for all $r = 1 \ldots s$, $\alpha_r n + \beta_r$ is not a perfect square.

Fix $\alpha \in (\mathbb{N} \setminus \{0\})^s$, $\beta \in \mathbb{Z}^s$. Let $F_N$ be the number of positive integers $1 \leq n \leq N$ which satisfy (NSC-$S_{\alpha, \beta}$).

Consider a single couple $(\alpha_r, \beta_r)$: the main result in \cite{2} implies that there exist two universal constants $C_1, C_2$ (which do not depend on $\alpha_r, \beta_r$), such that the number of positive integers $1 \leq n \leq N$ such that $\alpha_r n + \beta_r$ is a perfect square is at most $C_1 N^{3/5}(\ln N)^{C_2}$. Now, a positive integer $n$ fails to satisfy (NSC-$S_{\alpha, \beta}$) if and only if $\alpha_r n + \beta_r$ is a perfect square for at least one of the $s$ couples $(\alpha_r, \beta_r)$. Therefore, we deduce that the number of positive integers $\leq N$ which fail to satisfy (NSC-$S_{\alpha, \beta}$) is
\[
N - F_N \leq C_1 s N^{3/5}(\ln N)^{C_2}.
\]
Hence, we have
\[
N - C_1 s N^{3/5}(\ln N)^{C_2} \leq F_N \leq N
\]
which implies that $F_N$ is asymptotic to $N$ as $N \to +\infty$. In particular, this implies that there are infinitely many positive integers satisfying \((\text{NSC-S}_{\alpha\beta})\), which in turn implies that one can choose $n_{K+1}$ arbitrarily large and satisfying \((\text{NSC-S}_{\alpha\beta})\). This concludes the proof of Proposition 2.2.

3. The model equation

Recall that

\[ A_k = \{n_k - 2, n_k - 1, n_k + 1, n_k + 2\}, \quad A = \bigcup_{k=1}^{K} A_k, \]
and the notation (1.4). We assume that \((n_k)_{k \geq 1}\) is a sequence which satisfies Lemma 2.1 and Proposition 2.2.

Next, we set $\varepsilon = \nu^{1/4}$ and make the change of unknown $v = \varepsilon u$. Therefore $v$ satisfies

\[
\begin{aligned}
&i\partial_t v + \partial_x^2 v = |v|^4 v, \quad (t, x) \in \mathbb{R} \times S^1, \\
&v(0, x) = v_0(x) = \varepsilon u_0(x).
\end{aligned}
\]

We expand $v$ and $\bar{v}$ in Fourier modes

\[ v(x) = \sum_{j \in \mathbb{Z}} \xi_j e^{ijx}, \quad \bar{v}(x) = \sum_{j \in \mathbb{Z}} \eta_j e^{-ijx}, \]

and denote by $H = \int_{S^1} |\partial_x v|^2 + \frac{1}{3} \int_{S^1} |v|^6$ the Hamiltonian of (3.1).

We now refer to [5, Section 3], and in particular to Proposition 3.1 and Proposition 3.3. It is proven that, thanks to a Birkhoff normal form procedure, that there exists a symplectic change of coordinates $\tau$ close to the identity so that

\[
\mathcal{H} := H \circ \tau = N + Z_6 + R_{10},
\]

where

- $N$ only depends on the actions \((I_k)_{k \in \mathbb{Z}}\);
- $Z_6$ is the homogeneous polynomial of degree 6:

\[ Z_6 = \sum_{R} \xi_{j_1} \xi_{j_2} \xi_{j_3} \eta_{l_1} \eta_{l_2} \eta_{l_3}. \]

- $R_{10}$ is a remainder of order 10.

As in [5, Section 4], we introduce the model system by setting $\xi_j^0 = \eta_j^0 = 0$ in (3.2) when $j \notin A$. This induces here the Hamiltonian

\[ \hat{H} = 6J^3 + \sum_{k=1}^{K} \hat{H}_k, \]

where

\[ \hat{H}_k = \sum_{j \in A_k} j^2 I_j - 9J \sum_{j \in A_k} I_j^2 + 4 \sum_{j \in A_k} I_j^3 + 18J^{1/2} I_{a_2(k)}^{1/2} I_{a_1(k)} I_{b_1(k)} \cos(2\varphi_0^{(k)}), \]

with $\varphi_0^{(k)} = \theta_{a_1(k)} - \theta_{b_1(k)} + \frac{1}{2} \theta_{a_2(k)} - \frac{1}{2} \theta_{b_2(k)}$. 

\[ DYNAMICS ON RESONANT CLUSTERS FOR NLS \]
Since $\hat{H}$ is almost decoupled, we obtain a completely integrable system.

**Lemma 3.1.** — The system given by $\hat{H}$ is completely integrable.

**Proof.** — Since $J$ is a constant of motion, this is a direct consequence of \[5\] Lemma 4.1. Indeed, for all $1 \leq k \leq K$, $\hat{H}_k$ and

$$K_1^{(k)} = I_{a_1^{(k)}} + I_{b_1^{(k)}}, \quad K_2^{(k)} = I_{a_2^{(k)}} + I_{b_2^{(k)}} \quad \text{and} \quad K_{1/2}^{(k)} = I_{b_2^{(k)}} + \frac{1}{2} I_{a_1^{(k)}},$$

are constants of motion in involution. 

As in \[5\], we use the coordinates $(\varphi, K)$ to describe some particular trajectories of $\hat{H}$. To begin with, $\hat{H}_k$ can be rewritten

$$\hat{H}_k = \tilde{H}_k(\varphi_0^{(k)}, K_0^{(k)}, K_1^{(k)}, K_2^{(k)}, K_{1/2}^{(k)})$$

$$= F_k(K_1^{(k)}, K_2^{(k)}, K_{1/2}^{(k)}) + 6 \left[(3J - 2K_1)I_{a_1}I_{b_1} + (3J - 2K_2)I_{a_2}I_{b_2} + 3I_{a_2}I_{b_2}I_{a_1}I_{b_1}\cos(2\varphi_0)\right],$$

for some polynomial $F_k$. Next, we define

$$\varepsilon_k = \varepsilon e^{-nk},$$

we fix

$$K_1^{(k)} = \varepsilon_k^2, \quad K_2^{(k)} = \frac{1}{2} \varepsilon_k^2 \quad \text{and} \quad K_{1/2}^{(k)} = \frac{1}{2} \varepsilon_k^2,$$

and denote by $K_0^{(k)} = I_{a_1^{(k)}}$. With the previous choice,

$$J = \sum_{k \geq 1} (K_1^{(k)} + K_2^{(k)}) = \frac{3}{2} \varepsilon^2 \sum_{k \geq 1} e^{-2nk} = C \varepsilon^2.$$

The following rescaling proves to be useful

$$\varphi_0^{(k)}(t) = \varphi^{(k)}(\varepsilon_k^4 t), \quad K_0^{(k)}(t) = \varepsilon_k^2 K^{(k)}(\varepsilon_k^4 t).$$

Define

$$H_*^{(k)} = \frac{9}{4} K^{(k)}(1 - K^{(k)}) \left[10 J \varepsilon_k^{-2} - 6\right] + 4(K^{(k)})^\frac{3}{2} (1 - K^{(k)})^\frac{3}{2} \cos(2\varphi^{(k)})\right],$$

and

$$H_* = \sum_{k = 1}^K H_*^{(k)},$$

then for all $1 \leq k \leq K$, the evolution of $(\varphi^{(k)}, K^{(k)})$ is given by

$$\begin{cases}
\dot{\varphi}^{(k)} = -\frac{\partial H_*}{\partial K^{(k)}} = -\frac{27}{4} (1 - 2K^{(k)}) \left[\frac{10}{3} J \varepsilon_k^{-2} - 2\right] + 2(K^{(k)})^\frac{3}{2} (1 - K^{(k)})^\frac{3}{2} \cos(2\varphi^{(k)})
\end{cases}$$

$$\dot{K}^{(k)} = -\frac{\partial H_*}{\partial \varphi^{(k)}} = -18(K^{(k)})^\frac{3}{2} (1 - K^{(k)})^\frac{3}{2} \sin(2\varphi^{(k)}).$$

1. The expression of $F_k$ which can be found in \[5\] is incomplete and it lacks the dependence of $F_k$ on $K_{1/2}^{(k)}$. However, this does not affect the results in \[5\].
Then by [5] Proposition 4.2] we have

**Proposition 3.2.** — For all \( k \geq 1 \), there exists a \( \gamma_k \in (0, 1/2) \) so that if \( \gamma_k < K^{(k)}(0) < 1 - \gamma_k \) and \( \varphi(0) = 0 \), then there is \( T_k > 0 \) so that \( (\varphi^{(k)}, K^{(k)}) \) is a \( 2T_k \)-periodic solution of (3.7) and

\[
K^{(k)}(0) + K^{(k)}(T_k) = 1.
\]

Moreover, \( T_k : (\gamma_k, 1/2) \cup (1/2, 1 - \gamma_k) \rightarrow \mathbb{R} \) is a continuous function of \( K^{(k)}(0) \),

\[
T_k \rightarrow \frac{2\pi}{9} (10J_{\varepsilon_k}^{-2} - 3)^{-1/2} \quad \text{as} \quad K^{(k)}(0) \rightarrow 1/2,
\]

and

\[
T_k \rightarrow +\infty \quad \text{as} \quad K^{(k)}(0) \rightarrow \gamma_k.
\]

**Proof.** — Denote by \( C_k = 10J_{\varepsilon_k}^{-2} - 6 \). With (3.4), we have \( C_k \geq 9 \) and \( C_k \sim \varepsilon^{2n_k} \). Write here \( K^{(k)} = K \) and \( \varphi^{(k)} = \varphi \). Then, as for the proof of [5] Proposition 4.2],

\[
K(1 - K) (C_k + 4K^{1/2}(1 - K)^{1/2} \cos(2\varphi)) = \frac{1}{4} (C_k - 2)
\]

defines two heterocline orbits which link the saddle points \( (\varphi, K) = (-\pi/2, 1/2) \) and \( (\varphi, K) = (-\pi/2, 1/2) \). When \( \varphi = 0 \)

\[
K^{1/2}(1 - K)^{1/2} = D_k := \frac{C_k - 2}{\sqrt{(C_k - 2)^2 + 8(C_k - 2)}}.
\]

Observe that, since \( C_k \geq 9 > 2 \), \( D_k \in (0, 1/2) \), and this yields the existence of \( \gamma_k \).

Moreover, \( T_k \) is a continuous function of \( K^{(k)}(0) \) on \( (\gamma_k, 1/2) \cup (1/2, 1 - \gamma_k) \) and \( T_k \rightarrow +\infty \) when \( K^{(k)}(0) \rightarrow \gamma_k \), due to the continuous dependence on initial conditions.

Finally, since the point \( (\varphi, K) = (0, 1/2) \) is a nondegenerate centre, we have that \( T_k \) approaches the value of the half-period of the linearized system as \( K^{(k)}(0) \rightarrow 1/2 \) (it follows from the Theorem in Chapter 5.C, p.100, [1]). Since, in particular, we have

\[
\frac{\partial^2 H^*}{\partial K^2}(0, 1/2) = -\frac{9}{2}(C_k + 3), \quad \frac{\partial^2 H^*}{\partial \varphi^2}(0, 1/2) = -\frac{9}{2}, \quad \frac{\partial^2 H^*}{\partial K \partial \varphi}(0, 1/2) = 0,
\]

we deduce

\[
\lim_{k^{(k)}(0) \rightarrow 1/2} T_k = \frac{2\pi}{9\sqrt{C_k + 3}}.
\]

\[\Box\]

4. The perturbation analysis and proof of the main results

We are now ready to complete the proof of Theorem 1.2. This is a direct application of the results of [5] Section 5.

We now assume that \( n_k \leq -(\ln \varepsilon)/8 = -(\ln \nu)/32 \), therefore by (3.3) we have for all \( k \geq 1 \)

\[
\varepsilon^{9/8} \leq \varepsilon_k \leq \varepsilon.
\]

Then we can state the following result, which is analogous to [5] Lemma 5.1].
Lemma 4.1. — Assume that there exists $C > 0$ so that
\[ |\xi_j(0)|, |\eta_j(0)| \leq C \varepsilon^{-n_k}, \forall j \in \mathcal{A}_k \]
and
\[ |\xi_p(0)|, |\eta_p(0)| \leq C \varepsilon^3 e^{-|p|}, \forall p \notin \mathcal{A}. \]
Then for all $0 \leq t \leq C \varepsilon^{-6}$,
\[ I_p(t) = O(\varepsilon^6) \quad \text{when} \quad p \notin \mathcal{A}, \]
and
\[ K_1^{(k)}(t) = K_1^{(k)}(0) + O(\varepsilon^{10})t \\
K_2^{(k)}(t) = K_2^{(k)}(0) + O(\varepsilon^{10})t \\
K_{1/2}^{(k)}(t) = K_{1/2}^{(k)}(0) + O(\varepsilon^{10})t. \]

We consider the initial conditions
\[ K_1^{(k)}(0) = \varepsilon_k^2, \quad K_2^{(k)}(0) = \frac{1}{2} \varepsilon_k^2, \quad K_{1/2}^{(k)}(0) = \frac{1}{2} \varepsilon_k^2, \]
and $|\xi_j(0)|, |\eta_j(0)| \leq C \varepsilon^3 e^{-|j|}$ for $j \notin \mathcal{A}$.

Proposition 4.2. — Consider the solution of the Hamiltonian system given by $\mathbf{H}$ with the initial conditions (4.1). Then for all $1 \leq k \leq K$, $(\varphi^{(k)}, K^{(k)})$ defined by (3.5) satisfies for $0 \leq \tau_k \leq \varepsilon^{-6} \varepsilon_k^2$
\[ \left\{ \begin{array}{l}
\varphi^{(k)}(\tau_k) = -\frac{\partial H}{\partial K^{(k)}} + O(\varepsilon^2) \\
K^{(k)}(\tau_k) = -\frac{\partial H}{\partial \varphi^{(k)}} + O(\varepsilon^2),
\end{array} \right. \]
where $H_*$ is the Hamiltonian (3.6).

4.1. Proof of Theorem 1.2. — We choose the initial conditions for $(\varphi, K)$. We take $\varphi^{(k)}(0) = 0$ and $\gamma_k < K^{(k)}(0) < 1 - \gamma_k$. We also consider the solution $(\varphi_*, K_*)$ to (5.7) with initial condition $(\varphi_*^{(k)}, K_*^{(k)})(0) = (\varphi^{(k)}, K^{(k)})(0)$. Then by Proposition 4.2 and Lemma 5.3\footnote{As here, in [5] Lemma 5.3 there is actually an additional error term $O(\varepsilon^2)\tau^2$. This restrains the main result in [5] to times $t \leq \varepsilon^{-5} = \nu^{-5/4}$.} for all $0 \leq \tau_k \leq \varepsilon^{-5} \varepsilon_k^2$ we have
\[ (\varphi^{(k)}, K^{(k)})(\tau_k) = (\varphi_*, K_*)^{(k)}(\tau_k) + O(\varepsilon^2)\tau_k + O(\varepsilon^2)\tau_k^2, \]
which in turn implies that for all $0 \leq t \leq \varepsilon^{-5}$
\[ K_0^{(k)}(t) = \varepsilon_k^2 K_0^{(k)}(\varepsilon_k t) + O(\varepsilon^2 \varepsilon_k^2 t) + O(\varepsilon^2 \varepsilon_k^2 t^2) \\
\varphi_0^{(k)}(t) = \varepsilon_k^2 \varphi_0^{(k)}(\varepsilon_k t) + O(\varepsilon^2 \varepsilon_k^2 t) + O(\varepsilon^2 \varepsilon_k^2 t^2). \]
For $t \leq \varepsilon^{-9/2} = \nu^{-9/8}$ we get (1.5).

The period of $K_0^{(k)}$ is $2T_k \varepsilon_k^{-1} = 2T_k \varepsilon^{-4} e^{4n_k}$, thus one has to ask that
\[ 2T_k e^{4n_k} \leq \varepsilon^{-1/2} = \nu^{-1/8}. \]
In view of Proposition 3.2, we have that, depending on the choice of initial data, $T_k$ spans at least the open interval $(\frac{2\pi}{9}(10J\varepsilon_k^2 - 3)^{-1/2}, +\infty)$, which contains the interval $(\pi/(9\sqrt{3}), +\infty)$ for all $k$, so we can choose the initial data in such a way that $T_k = 1/2$ for all $k$. Therefore, since $n_k \leq n_K$, (4.2) is satisfied provided that $n_K \leq -1/32 \ln \nu$.

4.2. **Proof of Corollary 1.3.** — For each $k$, the period of $v_k$ equals the period of $K_k^{(k)}$, whose value is $2\nu^{-1}T_ke^{4n_k}$. In the proof of Theorem 1.2 we have observed that, given any $T \in (\pi/(9\sqrt{3}), +\infty)$, one can choose the initial data in such a way that $T_k = T$. This, with $n_k \leq n_K$, implies that, for any given $\Lambda \in (\pi e^{4n_k}/(9\sqrt{3}), +\infty)$, one can choose the initial data so that the period of $v_k$ is equal to $2\Lambda/\nu$. Therefore, given any $K \geq 1$ and any $\Lambda_1, \Lambda_2, \ldots, \Lambda_K > 0$, there exists $N \in \mathbb{N}$ so that, with a proper choice of the initial data, $v_k$ has period $2N\Lambda_k/\nu$, if $\nu$ is small enough. It suffices to choose the smallest $N$ such that $N\Lambda_k > \pi e^{4n_k}/(9\sqrt{3})$ for all $k$, which is admissible if for the chosen $N$ one has $N\Lambda_k < \nu^{-1/8}$ for all $k$, which is verified provided that $\nu$ is small enough.
