Abstract—Usually, the joint transmission friction model for robots is composed of a viscous friction force and of a constant dry sliding friction force. However, according to the Coulomb law, the dry friction force depends linearly on the load driven by the transmission. It follows that this effect must be taken into account for robots working with large variation of the payload or inertial and gravity forces, and actuated with transmissions as speed reducer, screw-nut or worm gear. This paper proposes a new inverse dynamic identification model for n degrees of freedom (dof) serial robot, where the dry sliding friction force \( F_c \) is a linear function of both the dynamic and the external forces, with a velocity-dependent coefficient. A new identification procedure groups all the joint data collected while the robot is tracking planned trajectories with different payloads to get a global least squares estimation of inertial and new friction parameters. An experimental validation is carried out with a joint of an industrial robot.

I. INTRODUCTION

The usual identification method is based on the inverse dynamic model (IDM) which is linear in relation to the dynamic parameters, and uses least squares (LS) technique. This procedure has been successfully applied to identify inertial and friction parameters of a lot of prototypes and industrial robots [1]-[10]. An approximation of the kinematic Coulomb friction, \( F_{c,\text{sign}(q)} \), is widely used to model friction force at non zero velocity \( q \), assuming that the friction force \( F_c \) is a constant parameter. It is identified by moving the robot without any load (or external force) or with constant given payloads [9].

However, the Coulomb law suggests that \( F_c \) depends on the transmission force driven in the mechanism. It depends on the dynamic and on the external forces applied through the joint drive chain. Consequently for robots with varying load, the identified IDIM is no more accurate when the transmission uses industrial speed reducer, screw-nut or worm gear because their efficiency significantly varies with the transmitted force. The significant dependence on load has been often observed for transmission elements [15]-[19] through direct measurement procedures. Moreover, the mechanism efficiency depends on the sense of power transfer leading to two distinct sets of friction parameters. In addition, when the robot moves at very low velocity, as for teleoperation, one observes a velocity-dependency of the dry friction.

This paper presents a new inverse dynamic identification model for n degrees of freedom (dof) serial robot, where the dry sliding friction force \( F_c \) is a linear function of both the dynamic and the external forces, with asymmetrical behavior depending on the signs of joint force and velocity, and a variation depending on the velocity amplitude. A new identification procedure is proposed. All the joint position and joint force data collected in several experiments, while the robot is tracking planned trajectories with different payloads, are concatenated to calculate a global least squares estimation of both the inertial and the new friction parameters.

An experimental validation is carried out on the third joint of an industrial robot: Stäubli RX130L [25]. Both models are compared.

II. USUAL INVERSE DYNAMIC MODELING AND IDENTIFICATION

A. Modeling

In the following, all mechanical variables are given in SI units in the joint space. All forces, positions, velocities and accelerations have a conventional positive sign in the same direction. That defines a motor convention for the mechanical behavior.

The dynamic model of a rigid robot composed of \( n \) moving links is written as follows [11]:

\[
\tau_{\text{dyn}} = \tau_\text{in} + \tau_f + \tau_{\text{ext}}
\]  

(1)

where:

- \( \tau_{\text{dyn}} \) is the (nx1) vector of dynamic forces due to the inertial, centrifugal, Coriolis, and gravitational effects:

\[
\tau_{\text{dyn}} = M(q)\ddot{q} + C(q, \dot{q})\dot{q} + Q(q)
\]  

(2)

where \( q, \dot{q}, \ddot{q} \) are respectively the (nx1) vectors of generalized joint positions, velocities and accelerations, \( M(q) \) is the (n xn) robot inertia matrix, \( C(q, \dot{q}) \) is the (n xn) matrix of centrifugal and Coriolis effects, \( Q(q) \) is the (nx1) vector of gravitational forces.

- \( \tau_\text{in} \) is the (nx1) input torque vector on the motor side of the drive chain:
\[ \mathbf{\tau}_{m} = g_{f}(v_{f} - v_{f_{0}}) \]  
\[ \text{where } v_{f} \text{ is the (nx1) vector of current references of the current amplifiers, } v_{f_{0}} \text{ is a (nx1) vector of amplifiers offsets,} \]
\[ g_{f} = NG, K_{i} \]
\[ N \text{ is the (nxn) gear ratios matrix of the joint drive chains} \]
\[ \dot{q}_{m} = N \dot{\mathbf{q}} \]  
\[ \text{with } \dot{q}_{m} \text{ the (nx1) velocities vector on the motor side,} \]
\[ G_{i} \text{ is the (nxn) static gains diagonal matrix of the current amplifiers,} \]
\[ K_{i} \text{ is the (nxn) diagonal matrix of the electromagnetic motor torque constants} \]
\[ \mathbf{\tau}_{f} \text{ is the (nx1) vector of the loss force due to friction.} \]
\[ \rho \text{ is the (nx1) vector of the loss force due to frictions.} \]
\[ \mathbf{\tau}_{ext} \text{ is the (nx1) external forces vector in the joint space.} \]
\[ \mathbf{\tau}_{f} = -F_{v}\dot{\mathbf{q}} - F_{c}\mathbf{sign}(\dot{\mathbf{q}}) - F_{\text{off}} \]
\[ \text{where } F_{v} \text{ is the (nxn) diagonal matrix of viscous parameters,} \]
\[ F_{c} \text{ is the (nxn) diagonal matrix of dry friction parameters, and} \]
\[ \mathbf{sign}(.) \text{ denotes the sign function,} \]
\[ F_{\text{off}} \text{ is a (nx1) vector of asymmetrical Coulomb friction force} \]
\[ \mathbf{\tau}_{d} = -M(q\dot{\mathbf{q}} + C(q, \dot{\mathbf{q}}) + Q(q)) + F_{c}\mathbf{sign}(\dot{\mathbf{q}}) + F_{\text{off}} - \mathbf{\tau}_{ext} \]
\[ \text{is the motor force, without offset, and defined by } v_{f} \text{ which is the current reference calculated by the numerical control and stored for the identification.} \]
\[ \mathbf{\tau} = D_{s}(q, \dot{\mathbf{q}}, \ddot{\mathbf{q}}) \]
\[ \text{where } D_{s}(q, \dot{\mathbf{q}}, \ddot{\mathbf{q}}) \text{ is the regressor and } z_{s} \text{ is the vector of the standard parameters which are the coefficients } X_{x}, X_{y}, \]
\[ \text{of } \mathbf{K}_{j} \text{ the mass of the link } j \text{ called } m_{j}, \]
\[ \text{the first moments vector of link } j \text{ around the origin of frame } j \text{ denoted } \mathbf{I}_{j} \]
\[ \mathbf{F}_{\text{off}} \text{ is a (nxn) static gains diagonal matrix of the current amplifiers,} \]
\[ \mathbf{F}_{\text{off}} \text{ is a (nxn) static gains diagonal matrix of the current amplifiers,} \]
\[ \mathbf{\tau}_{ext} \text{ is the (nx1) vector of the loss force due to friction.} \]
\[ \mathbf{\tau}_{f} = -F_{v}\dot{\mathbf{q}} - F_{c}\mathbf{sign}(\dot{\mathbf{q}}) - F_{\text{off}} \]
\[ \text{where } F_{v} \text{ is the (nxn) diagonal matrix of viscous parameters,} \]
\[ F_{c} \text{ is the (nxn) diagonal matrix of dry friction parameters, and} \]
\[ \mathbf{sign}(.) \text{ denotes the sign function,} \]
\[ F_{\text{off}} \text{ is a (nx1) vector of asymmetrical Coulomb friction force} \]
\[ \mathbf{\tau}_{d} = -M(q\dot{\mathbf{q}} + C(q, \dot{\mathbf{q}}) + Q(q)) + F_{c}\mathbf{sign}(\dot{\mathbf{q}}) + F_{\text{off}} - \mathbf{\tau}_{ext} \]
\[ \text{is the motor force, without offset, and defined by } v_{f} \text{ which is the current reference calculated by the numerical control and stored for the identification.} \]
\[ \mathbf{\tau} = D_{s}(q, \dot{\mathbf{q}}, \ddot{\mathbf{q}}) \]
\[ \text{where } D_{s}(q, \dot{\mathbf{q}}, \ddot{\mathbf{q}}) \text{ is the regressor and } z_{s} \text{ is the vector of the standard parameters which are the coefficients } X_{x}, X_{y}, \]
\[ \text{of } \mathbf{K}_{j} \text{ the mass of the link } j \text{ called } m_{j}, \]
\[ \text{the first moments vector of link } j \text{ around the origin of frame } j \text{ denoted } \mathbf{I}_{j} \]
\[ \mathbf{K}_{i} \text{ is the (nxn) static gains diagonal matrix of the current amplifiers,} \]
\[ \mathbf{K}_{i} \text{ is the (nxn) static gains diagonal matrix of the current amplifiers,} \]
\[ \mathbf{\tau}_{ext} \text{ is the (nx1) external forces vector in the joint space.} \]
\[ \mathbf{\tau}_{f} = -F_{v}\dot{\mathbf{q}} - F_{c}\mathbf{sign}(\dot{\mathbf{q}}) - F_{\text{off}} \]
\[ \text{where } F_{v} \text{ is the (nxn) diagonal matrix of viscous parameters,} \]
\[ F_{c} \text{ is the (nxn) diagonal matrix of dry friction parameters, and} \]
\[ \mathbf{sign}(.) \text{ denotes the sign function,} \]
\[ F_{\text{off}} \text{ is a (nx1) vector of asymmetrical Coulomb friction force} \]
\[ \mathbf{\tau}_{d} = -M(q\dot{\mathbf{q}} + C(q, \dot{\mathbf{q}}) + Q(q)) + F_{c}\mathbf{sign}(\dot{\mathbf{q}}) + F_{\text{off}} - \mathbf{\tau}_{ext} \]
relative standard deviation \( \% \sigma_{\dot{x}} \) is given by:

\[
\% \sigma_{\dot{x}} = 100 \sigma_{\dot{x}}/\dot{x}
\]  

However, experimental data are corrupted by noise and error modeling and \( W \) is not deterministic. This problem can be solved by filtering the measurement vector \( Y \) and the columns of the observation matrix \( W \) as described in [7], [8].

### III. New Dry Friction Model and Identification

In this section, we introduce a dry friction model dependent on the load, that is \( \tau_{\text{out}} \), and on the velocity \( \dot{q} \).

#### A. Load-Dependent Friction Model

The Coulomb friction is still written \( F_c \cdot \text{sign}(\dot{q}) \), with \( F_c \) a (nxn) diagonal matrix. But here, for each link \( j \), \( F_{C(j,j)} \) (the \((j,j)^{th}\) element of the matrix \( F_c \)) depends linearly on the absolute value of the load of joint \( j \) which is \( \tau_{\text{out}j} \) (Fig. 1.b), [15]-[19]. As one can see in II.B, \( \tau_{\text{out}j} \) is a function of \( q, \dot{q}, \ddot{q} \) and is linear in relation to base parameters.

Then the inverse dynamic model for each link \( j \) becomes:

\[
\tau_j = \tau_{\text{out}j} + (\alpha_j \tau_{\text{out}j} + \beta_j) \text{sign}(\dot{q}_j) + F_{C(j,j)} \dot{q}_j + \tau_{\text{eff}j}
\]  

where \( \alpha_j \) and \( \beta_j \) are parameters to be identified. These new parameters depend on the mechanical structure of the reducers used to actuate the robot.

For ease of understanding, the subscript \( j \) is omitted for all variables in the following to simplify the notation.

- a) \(- (\tau_j + F_{\text{cap}}) \)
- b) \(- (\tau_j + F_{\text{eff}}) \)
- c) \(- (\tau_j + F_{\text{eff}}) \)

Fig. 1. a) Usual friction model with constant dry friction + viscous friction. b) Model with load-dependent dry friction + viscous friction. c) Model with load- and velocity-dependent dry friction + viscous friction.

The inverse dynamic model can be written as follows:

\[
\tau = \tau_{\text{out}} + \alpha \tau_{\text{out}} \text{sign}(\dot{q}) + \beta \text{sign}(\dot{q}) + F_{\text{r}} \dot{q} + \tau_{\text{eff}}
\]

And with \( \tau_{\text{out}} = \tau_{\text{out}} \text{sign}(\tau_{\text{out}}) \) and \( \text{sign}(\tau_{\text{out}}) \text{sign}(\dot{q}) = \text{sign}(\tau_{\text{out}}) \dot{q} = \text{sign}(\tau_{\text{out}}) \dot{q} \), one obtains:

\[
\tau = \tau_{\text{out}} + \alpha \tau_{\text{out}} \text{sign}(\tau_{\text{out}}) + \beta \text{sign}(\dot{q}) + F_{\text{r}} \dot{q} + \tau_{\text{eff}}
\]  

Thus, the IDM depends on the signs of the output power \( P_{\text{out}} = \tau_{\text{out}} \dot{q} \). One defines 4 quadrants in the frame \( (\dot{q}, \tau_{\text{out}}) \), which can be grouped two by two (Fig. 2.a). In the quadrants 1 and 3, \( P_{\text{out}} \) is positive and the actuator has a motor behavior. In the quadrants 2 and 4, \( P_{\text{out}} \) is negative and the actuator has a generator behavior which may save the power to the power supply, assuming a 4 quadrants amplifier.

#### B. Dry Friction Model Depending on the Power Sign

In the model (19), \( \alpha \) and \( \beta \) do not depend on the output power sign. But, generally they take different values: \( \alpha_m \) and \( \beta_m \) for the motor quadrants, and \( \alpha_g \) and \( \beta_g \) for the generator quadrants.

\[
\begin{cases}
P_{\text{out}} > 0 & \Rightarrow \tau = (1 + \alpha_m) \tau_{\text{out}} + \beta_m \text{sign}(\dot{q}) + F_v \dot{q} + \tau_{\text{eff}} \\
P_{\text{out}} < 0 & \Rightarrow \tau = (1 - \alpha_g) \tau_{\text{out}} + \beta_g \text{sign}(\dot{q}) + F_v \dot{q} + \tau_{\text{eff}}
\end{cases}
\]

The model (20) is illustrated in Fig. 2.b for a constant velocity \( \dot{q}_0 \). This model is not valid anymore for very low forces in the stiction area (\( \dot{q} = 0 \)): one approximates the friction as the limit of model (20) in the rectangle \((\beta_m + F_{F[\dot{q}_0]} + \tau_{\text{eff}} ; (\beta_m + F_{\ddot{q}_0} - \tau_{\text{eff}}) / (1 - \alpha_g)\).

![Fig. 2. a) Four quadrants frame (\( \dot{q}, \tau_{\text{out}} \)) for motor or generator behavior. b) Asymmetrical friction for a given velocity \( \dot{q}_s \) and the stiction area.](image)

#### C. Dry Friction Model Depending on the Velocity

For a robot moving at low velocities, one observes a dry friction variation, functions of the velocity, which is similar to the Stribeck model (Fig. 1.c), [20], [21], [22].

\[
F = F_{\text{sl}} \text{sign}(\tau_{\text{out}}) \quad \text{if } \dot{q} = 0 \quad \text{and } \tau_{\text{out}} < F_{\text{sl}}
\]

\[
F = F_{\text{sl}} \text{sign}(\tau_{\text{out}}) \quad \text{if } \dot{q} = 0 \quad \text{and } \tau_{\text{out}} \geq F_{\text{sl}}
\]

with:

\[
F(\dot{q}) = \left(F_{\text{sl}} + (F_{\text{sl}} - F_{\text{sl}}) e^{-1/\dot{q}_s^2}\right) \text{sign}(\dot{q})
\]

where \( \dot{q}_s \) is a velocity constant, \( F_{\text{sl}} \) is the dry friction in stiction and \( F_{\text{sl}} \) is the dry friction in sliding mode.

To combine the variation due to the load (17) with the one due to velocity (22), one takes:

\[
F = \alpha \tau_{\text{out}} + \beta \quad \text{et} \quad F_{\text{sl}} = \gamma \tau_{\text{out}} + \delta
\]

Then, (22) becomes:
\[
F(\ddot{q}) = \left( \alpha \frac{\ddot{q}}{m_0} + \beta + (\gamma + \delta) \frac{\ddot{q}}{m_0} \right) + \delta - \alpha \frac{\ddot{q}}{m_0} - \beta e^{\frac{\ddot{q}}{m_0}} \text{sign}(\ddot{q})
\]
\[
= \alpha \frac{\ddot{q}}{m_0} \text{sign}(\ddot{q}) + \beta + (\delta - \beta) e^{\frac{\ddot{q}}{m_0}} \text{sign}(\ddot{q}) \tag{24}
\]

Because of the dependence on power sign, one has 2 sets of parameters \( \alpha, \beta, \gamma, \delta \) for the 2 behaviors: motor and generator. Considering \( a_m = 1 + \alpha_m, b_m = \gamma_m - \alpha_m, c_m = \beta_m, d_m = \delta - \beta_m \), and \( a_s = 1 - \alpha_s, b_s = \gamma_s - \alpha_s, c_s = \beta_s, d_s = \delta_s - \beta_s \), the inverse dynamic model becomes:

\[
\begin{align*}
\text{if } P_{out} > 0 & \implies \\
\tau &= a_{m,s} \dot{q} + b_{m,s} e^{\frac{\dot{q}}{m_0}} + c_{m,s} \text{sign}(\dot{q}) + d_{m,s} e^{\frac{\dot{q}}{m_0}} \text{sign}(\dot{q}) + F_e \ddot{q} + \tau_{ef} \\
\text{if } P_{out} < 0 & \implies \\
\tau &= a_{m,s} \dot{q} - b_{m,s} e^{\frac{\dot{q}}{m_0}} + c_{m,s} \text{sign}(\dot{q}) + d_{m,s} e^{\frac{\dot{q}}{m_0}} \text{sign}(\dot{q}) + F_e \ddot{q} + \tau_{ef} \tag{25}
\end{align*}
\]

D. Friction Identification Method

In order to keep an IDM linear in relation to the parameters, one decides on an a priori value of \( \dot{q}_s \). This constant represents the exponential transitional behavior between stiction and sliding, that is about \( 3 * \dot{q}_s \), more or less 5%.

Measurements show that the amplitude of this transitional behavior is close to 10% of the nominal velocity 1.2 rad/s, that is \( \dot{q}_s = 0.04 \text{ rad/s} \). A final adjustment to \( \dot{q}_s = 0.03 \text{ rad/s} \) at the moment of the identification gives a minimal residual \( \|p\| \) a little lower. This value for \( \dot{q}_s \) is close to the value given in [22] for a Kuka IR 161 robot.

Furthermore, the model (25) depends on the sign of \( P_{out} \), which is unknown. To overcome this problem, the samples of \( \tau \) measurements are selected outside of the stiction area (\( \dot{q} = 0 \) – Fig. 2.b) in order to get the same sign for \( \tau_{out} \) and \( \tau \). This allows to get the sign of \( P_{out} \) with:

\[
\text{sign}(P_{out}) = \text{sign}(\tau_{out}) \dot{q} = \text{sign}(\tau \dot{q}) = \text{sign}(P) \tag{26}
\]

One can then write the IDM linear in relation to parameters and use the LS technique. To have only one expression instead of two in (25), 3 variables are introduced, \( P^+, P^- \) and \( E_{sp} \), defined by:

\[
P^+ = \frac{1 + \text{sign}(P)}{2}, \quad P > 0 \implies P^+ = 1, \quad P < 0 \implies P^+ = 0 \tag{27}
\]
\[
P^- = \frac{1 - \text{sign}(P)}{2} = \bar{P}^+ \tag{28}
\]
\[
E_{sp} = e^{\frac{\dot{q}}{m_0}}. \tag{29}
\]

The inverse dynamic model is then written:

\[
\tau = P^+ (a_m + b_m E_{sp}) \dot{q} + P^- (a_s - b_s E_{sp}) \dot{q} + ... \\
... P^+ (c_m + d_m E_{sp}) \text{sign}(\dot{q}) + P^- (c_s + d_s E_{sp}) \text{sign}(\dot{q}) + F_e \ddot{q} + \tau_{ef} \tag{30}
\]

As \( \tau_{out} \) is linear in relation to parameters, so is \( \tau \).

IV. EXPERIMENTAL SETUP AND IDENTIFICATION

A. Study case: Stäubli RX130L Robot

The Stäubli RX130L robot is an industrial robot with 6 rotational joints. The joint 3 has been chosen for this study because unlike the joint 1, it has large gravity variation, and no compensation gravity spring contrary to the joint 2. The links 1 and 2 are lined up and locked in a vertical position. The arm 3 is composed of the links 4, 5 and 6 brought into line with the link 3 and locked (Fig. 3), with a total mass of about 30 kg and a length of 1.33 m. The maximum velocity is 1.2 rad/s and the maximum acceptable load at the extremity is 10 kg.

The inverse dynamic model of joint 3 is written:

\[
\tau_j = J_{ja} \ddot{q}_j + M_{ja} g \cos(q_j) + M_{ja} g \sin(q_j) + F_{e3} \text{sign}(\dot{q}_j) + F_e \ddot{q}_j + \tau_{e3} \tag{31}
\]

where:

- \( J _j = Ia_j + ZZ_j \) is the inertia moment \( Ia_j \) of the drive chain plus the inertia moment \( ZZ_j \) of the arm,
- \( g = 9.81 \text{ m/s}^2 \) is the gravity acceleration.

All variables and parameters are given in SI units on the joint space. In the following, the subscript 3 is omitted to simplify the notation.

\[
\ddot{q}_j > 0
\]

Fig. 3. RX130L drawing: joints 1, 2, 4, 5 and 6 locked in position.

B. Data Acquisition

The identification of dynamic parameters is carried out with and without payloads: two different additional masses can be fixed to the arm extremity. To excite properly the friction parameters to be identified, sinusoidal and trapezoidal velocities trajectories were used.

The estimation of \( \dot{q}_j \) and \( \ddot{q}_j \) are carried out with pass band filtering of \( q \) consisting of a low pass Butterworth filter and a central derivative algorithm. The Matlab function \texttt{filtfilt} can be used [23]. The motor torque is calculated using the current reference (7). In order to cancel high frequency ripple in \( \tau \), the vector \( Y \) and the columns of the observation matrix \( W \) are both low pass filtered and decimated. This parallel filtering procedure is carried out with the Matlab \texttt{decimate} function [2, 10].

C. Identification

To identify the load-dependent friction, measurements
with known payloads are used. Gravity and inertial forces due to the additional mass fixed to the robot extremity have to be added in the IDM.

Let $R_w$ be the frame set at the center of gravity $G_m$ of the additional mass $M_{aw}$ and parallel to the frame $R_a(x_a, y_a, z_a)$ linked to the arm (Fig. 3). One gives the inertia matrix $I_{ga}$ of the additional mass which is a disk with a radius $r$ and a thickness $l$:

$$I_{ga} = \begin{bmatrix}
M_a r^2 / 2 & 0 & 0 \\
0 & M_a (r^2 / 4 + l^2 / 12) & 0 \\
0 & 0 & M_a (r^2 / 4 + l^2 / 12)
\end{bmatrix}_{(g_a, r_a)}$$

(32)

The vector of translation between $R_a$ and $R_w$ is $T_a = \begin{bmatrix} L_a & 0 & 0 \end{bmatrix}^T$ and as the 2 frames are parallel, one can apply the Huygens theorem:

$$J_a = \begin{bmatrix}
M_a r^2 / 2 & 0 & 0 \\
0 & M_a (r^2 / 4 + l^2 / 12) & 0 \\
0 & 0 & M_a (r^2 / 4 + l^2 / 12) + M_a L_a^2
\end{bmatrix}_{(a, g_a)}$$

(33)

As the terms $r^2$ and $e^2$ are negligible, compared with $L_a^2$, one keeps only the term $M_a L_a^2 \hat{q}$. For the gravity, considering the vector of translation $T$, one has: $M_a L_a g \cos(q)$.

Thus, for the samples $\tau_{(k)}$ with an additional mass $M_{aw(k)}$, (31) becomes:

$$\tau_{(k)} = J\ddot{q} + M_a g \cos(q) + M_a g \sin(q) + M_{aw(k)} L_a \hat{q} + ... + M_{aw(k)} L_a g \cos(q) + F_{c} \text{sign}(\dot{q}) + F_v \dot{q} + \tau_{off}$$

(34)

where:

- $M_{aw(k)}$ is one of the additional masses, fixed to robot extremity, with accurate weighed values: 0 kg, 3.4584 kg and 6.970 kg,
- $L_a$ is the length from the joint 3 to the additional mass position (measured distance): 1.277 m

At a first step, to identify the usual model with all samples, one distinguishes the weighed mass $M_{aw}$ and the mass $M_{aw}$ estimated by the identification. Thus, the usual model is:

$$\tau_{(k)} = J\ddot{q} + M_a g \cos(q) + M_a g \sin(q) + ... + M_{aw(k)} L_a g \cos(q) + F_{c} \text{sign}(\dot{q}) + F_v \dot{q} + \tau_{off}$$

(35)

Then, the sampled measurements, for $k$ from 1 to 3, are concatenated using the $M_{aw(k)}$ corresponding to each experiment $(k)$, to get the linear system:

$$Y_{usual} = W_{usual} \chi_{usual} + \rho_{usual}$$

(36)

with the measurements vector, the observation matrix, and the vector of base parameters below:

$$Y_{usual} = \tau = \begin{bmatrix} \tau_{(1)}^T \\ \tau_{(2)}^T \\ \tau_{(3)}^T \\ \tau_{off}^T \end{bmatrix}$$

(37)

$$W_{usual} = \begin{bmatrix} q \ g \cos(q) \ g \sin(q) \\ M_a L_a (L_a \ddot{q} + g \cos(q)) \ g \sin(q) \ \dot{q} \ I \end{bmatrix}$$

(38)

$$\chi_{usual} = \begin{bmatrix} \chi' & M \chi & \frac{M_{aw}}{M_{aw}} & F_c & F_v & \tau_{off} \end{bmatrix}^T$$

(39)

At a second step, the proposed model is identified with:

$$Y_{new} = W_{new} \chi_{new} + \rho_{new}$$

(40)

with the measurements vector, the observation matrix, and the vector of base parameters defined as follows:

$$Y_{new} = Y_{usual} = \tau$$

(41)

$$W_{new} = \begin{bmatrix} P^T \ddot{q} \ P^T E_{q} \ddot{q} \ P^T g \cos(q) \\ \vdots \ P^T E_{q} g \cos(q) \ P^T g \sin(q) \ P^T E_{q} g \sin(q) \ P^T \end{bmatrix}$$

(42)

$$\chi_{new} = \begin{bmatrix} a_p J \ b_p J \ a_p M \ b_p M \ a_p M' \ b_p M' \ a_m b_m \ \vdots \ a_p J \ b_p J \ a_p M \ b_p M \ a_p M' \ b_p M' \ a_k b_k \ \vdots \ c_m d_m e_k \ F_v \ \tau_{off} \end{bmatrix}$$

(43)

The expressions of $W_{new}$ and $\chi_{new}$ are obtained by inserting $\tau_{aw} = J\ddot{q} + M_a g \cos(q) + M_a g \sin(q) + M_{aw} L_a g \cos(q)$ in the inverse dynamic model (30).

Here $P^*$, $P^+$, and $E_{q}$ are diagonal matrices, with:

$$P_{ij} = \frac{1 + \text{sign}(P_i)}{2}, \quad P_{ij} = \frac{1 - \text{sign}(P_i)}{2}, \quad E_{q} = e^{b \|v\|}$$

(44)

The two models are compared using exactly the same identification method with the same measurements.

D. Results

The significant values identified with usual IDM and OLS regressions are given in Table I and those with the new IDM in Table II (the parameters with a large relative deviation are not significant and have been eliminated). For each model, Fig. 4 and Fig. 5 present a direct validation comparing the actual $\tau$ with its predicted value $\hat{W}^2$. Moreover, Table III
presents the relative norm of errors $\|p\|/\|y\|$ for the two models and for several sets of experiments: all measurements (all velocities), with low velocities (0 to 10% of the maximum velocity) or high velocities (35% to 100% of the maximum velocity). Finally, Table IV compares the relative norms of errors for the two models, with two different identifications: the first one is carried out with all measurements, that is with variation of the payload fixed to arm extremity, and the second one is carried out with only the samples obtained without payload.

As one can see in all figures and tables, the new dynamic model improves the residual.

</tr>
</tbody>
</table>

V. DISCUSSION

The parameters of the new model are identifiable (low standard deviation) and so significant. The identification process does not change as the new model is still linear in relation to the parameters. The originality is that the global identification groups all measurements, with all payloads, in only one LS process. The main difficulty is to distinguish the different behaviours, motor and generator, but a solution has been proposed along this paper. One can also note that the measurements have to be more exciting than usual: each test has to be done with different loads and low velocities to highlight the effect on the friction variations. So, this identification protocol is more time-consuming and the setting up must be adapted for the measurements with additional masses.

The figures of direct validation show an improvement of the estimated torque by the new model, which is confirmed by the Table III. Indeed, one observes a decrease of 34% in the relative norm of errors. The improvement is mostly important for the low velocities where the errors are divided...
by two, thanks to the new model (decrease of 46%). At high velocity, the friction term with the exponential function approaches zero, and the new model is equivalent to the usual.

Moreover, the Table IV shows that the model is especially interesting for robots carrying some payloads. However, for a robot without payload but with high gravity variation, as the third joint of the RX130L, one obtains still a decrease of 19% of the errors.

Finally, this new model can be easily applied to a multi dof robot, using (30) for each joint $j$.

This model is important for example in teleoperation, where the robots work at reduced velocity and can carry payloads or perform tasks with the effector subjected to external forces.

VI. CONCLUSION

This paper has presented a new dry friction model, with load- and velocity-dependency, and its identification method. The inverse dynamic model and the identification of its parameters have been successfully validated on a rotational joint of an industrial robot. As a result, one observes a significant improvement comparing to the usual model, for joints with large load variations, and especially at low velocity. Robots carrying important masses or with large inertial or gravity variations are concerned. In addition, this technique can be applied to multi dof robots.

Future works concern the application of this model to the multi dof robot and for different types of transmission. Then, the model will be used for torques monitoring and collision detection.

ACKNOWLEDGMENT

The authors thank the AREVA society [24] for the availability of the Stäubli RX130L robot.
