REPORT

Channel Formation by Yeast F-ATP Synthase and the Role of Dimerization in the Mitochondrial Permeability Transition**

Received for publication, February 19, 2014, and in revised form, April 18, 2014

Purified F-ATP synthase dimers of yeast mitochondria display Ca\(^{2+}\)-dependent channel activity with properties resembling those of the permeability transition pore (PTP) of mammals. After treatment with the Ca\(^{2+}\) ionophore ETH129, which allows electrophoretic Ca\(^{2+}\)/H\(^{+}\) exchange, isolated yeast mitochondria undergo inner membrane permeabilization due to PTP opening. Yeast mutant strains \(\Delta TIM11\) and \(\Delta ATP20\) (lacking the e and g F-ATP synthase subunits, respectively, which are necessary for dimer formation) display a striking resistance to PTP opening. These results show that the yeast PTP originates from F-ATP synthase and indicate that dimerization is required for pore formation in situ.

Mitochondria from a variety of sources can undergo an inner membrane permeability increase, the permeability transition (PT),\(^4\) due to opening of a high conductance channel, the PT pore (PTP) (1). The PTP coincides with the mitochondrial megachannel (MMC) defined by patch clamp studies in mitochondria from various species (2–5). In mammals, PTP opening requires matrix Ca\(^{2+}\) and is favored by oxidative stress and P, induced by adenine nucleotides and Mg\(^{2+}\), and antagonized by cyclosporin A (CsA) through its interaction with matrix cyclophilin (CyP)D (6, 7). The mammalian PTP is today recognized to play a role in cell death in a variety of disease paradigms (8).

Inner membrane permeability pathways have been described in yeast (9) and in Drosophila melanogaster (10), but whether these coincide with the mammalian PTP remains an open question (11–14). The issue is particularly complex in the case of yeast, where multiple conductance pathways may exist including an uncoupling protein-independent permeability activated by ATP (15–17). Furthermore, the yeast PTP (yPTP) is inhibited rather than activated by P, and insensitive to CsA (9), and due to the lack of a mitochondrial Ca\(^{2+}\) uniporter, its Ca\(^{2+}\) dependency has been more difficult to assess (18), although the Ca\(^{2+}\) content of Saccharomyces cerevisiae mitochondria is close to that of rat liver mitochondria (19). The problem of the Ca\(^{2+}\) dependence was solved by the Shinohara group (20), who showed that yeast mitochondria incubated with optimized substrate and P concentrations readily undergo a Ca\(^{2+}\)-dependent PT upon treatment with ETH129, a Ca\(^{2+}\) ionophore that allows electrophoretic Ca\(^{2+}\) transport into the matrix of energized mitochondria. We recently demonstrated that dimers of mammalian F-ATP synthase reconstituted into planar bilayers give rise to Ca\(^{2+}\)-activated currents with conductances ranging up to 1.3 nS in 150 mM KCl that closely match those displayed by the MMC-PTP (21). Here we have tested whether gel-purified F-ATP synthase dimers of S. cerevisiae form channels when reconstituted in lipid bilayers, and whether dimerization of the F-ATP synthase is necessary for PTP formation in intact mitochondria.

EXPERIMENTAL PROCEDURES

Yeast Strains and Materials—The S. cerevisiae strains BY4743 (4741/4742), as well as the mutants \(\Delta CPR3\) (MATa, his3\(\Delta1\), leu2\(\Delta0\), met5\(\Delta0\), ura3\(\Delta0\)), \(\Delta TIM11\) (MATa, his3\(\Delta1\), leu2\(\Delta0\), met5\(\Delta0\), ura3\(\Delta0\)), and \(\Delta ATP20\) (MATa, his3\(\Delta1\), leu2\(\Delta0\), lys2\(\Delta0\), ura3\(\Delta0\)), were purchased from thermo Scientific. \(\Delta TIM11\Delta ATP20\) mutants were obtained by mating the \(\Delta TIM11\) and \(\Delta ATP20\) strains and selecting the formed diploid by growth on synthetic defined (0.67% nitrogen base without amino acids, 2% dextrose) selective medium containing the

\(^{4}\) The abbreviations used are: PT, permeability transition; PTP, permeability transition pore; yPTP, yeast permeability transition pore; BP-NAGE, blue native polyacrylamide gel electrophoresis; CRC, Ca\(^{2+}\) retention capacity; Cu(OP)\(_{2}\), copper-o-phanthrolinolate; CsA, cyclosporin A; CyP-D, cyclophosphilin D; MMC, mitochondrial megachannel; PhAsO, phenylarsine oxide; Tricine, N-[2-hydroxy-1,1-bis(hydroxymethyl)ethyl]glycine; Bis-Tris, 2-(bis(2-hydroxyethyl)aminoo)-2-(hydroxymethyl)propane-1,3-diol; S, siemens.
required nutritional supplements except methionine and lysine. Diploids were then induced to sporulate in 1% potassium acetate, tetrads were dissected, and haploids were analyzed with semiquantitative PCR to detect null mutants for TIM11 and ATP20 genes. Digitonin was from Sigma, and ETH129 was from Sigma-Aldrich Japan and was dissolved in methanol. NADH, disodium salt was purchased from Roche Applied Science.

**Yeast Culture and Mitochondria Isolation**—Yeast cells were cultured aerobically in 50 ml of 1% yeast extract, 1% bacto-polypeptone medium containing 2% glucose at 30 °C. When it reached an optical density of 2 at 600 nm, the culture was added to 800 ml of bacto-polypeptone medium supplemented with 2% galactose and incubated for 20 h at 30 °C under rotation at 180 rpm, yielding about 4.0 g of yeast cells. Yeast mitochondria were isolated as described (20) with the following modifications. Briefly, cells were washed, incubated for 15 min at 37 °C in a 0.1 M Tris-SO₄ buffer (pH 9.4) supplemented with 10 mM dithiothreitol (DTT), and washed once with 1.2 M sorbitol, 20 mM P₃, pH 7.4. Yeast cells were then suspended in the same buffer and incubated for 45 min at 30 °C with 0.4 mg/g of cells of Zymolyase 100T to form spheroplasts. The latter were washed once with sorbitol buffer and homogenized in 0.6 M Mannitol, 10 mM Tris-HCl, pH 7.4, and 0.1 mM EDTA-Tris with a Potter homogenizer. The homogenate was centrifuged for 5 min at 2,000 × g, and the supernatant was collected and centrifuged for 10 min at 12,000 × g. The resulting mitochondrial pellet was suspended in mannitol buffer, and protein concentration was determined from the \( \Delta A_{280} \) of SDS-solubilized mitochondria (14).

**Mitochondrial Calcium Retention Capacity**—Mitochondrial Ca\(^{2+}\) uptake was measured with Calcium Green-5N (Molecular Probes) fluorescence using a Fluoroskan Ascent FL (Thermo Electron) plate reader at a mitochondrial concentration of 0.5 mg mL\(^{-1}\). Mitochondria were incubated as specified in the figure legends.

**Gel Electrophoresis and Western Blotting**—Mitochondria were suspended at 10 mg/ml in 150 mM potassium acetate, 30 mM HEPES, 10% glycerol, 1 mM phenylmethylsulfonyl fluoride and solubilized with 1.5% (w/v) digitonin. After centrifugation at 100,000 × g with a Beckman TL-100 rotor for 25 min at 4 °C, supernatants were collected, supplemented with 50 mg/ml Coomassie Blue and 5 mM aminocaproic acid, and quickly loaded onto a blue native polyacrylamide 3–12% gradient gel (BN-PAGE, Invitrogen). Electrophoresis was carried out at 150 V for 20 min and at 250 V for 2 h followed by gel staining with 0.25 mg/ml Coomassie Blue, 10% acetic acid or used for in-gel activity staining to detect bands corresponding to ATP synthase. Activity was monitored in 270 mM glycine, 35 mM Tris, pH 7.4, 15 mM MgSO\(_4\), 8 mM ATP, Tris-buffered to pH 7.4, and 2 mg/ml Pb(NO\(_3\))\(_2\). Bands corresponding to monomeric and dimeric forms of ATP synthase were cut from the gels, and protein complexes were eluted overnight by incubation at 4 °C in 25 mM Tricine, 15 mM MgSO\(_4\), 8 mM ATP, 7.5 mM Bis-Tris, 1% (w/v) n-heptyl \( \beta \)-d-thioglucopyranoside, pH 7.0. Samples were then centrifuged at 20,000 × g for 10 min at 4 °C, and supernatants were used for bilayer experiments. For cross-linking experiments, mitochondria were incubated 20 min at room temperature at 1 mg/ml in 250 mM sucrose, 2 mM P₃, and 2 mM CuCl\(_2\). Five millimolar N-ethylmaleimide and 5 mM EDTA were then added to block the cross-linking reaction, and the incubations were transferred on ice for 10 min followed by centrifugation and preparation for BN-PAGE as described above. Total yeast mitochondria lysates and bands corresponding to dimers of F-ATP synthase cut out of BN-PAGE gels were subjected to SDS-PAGE followed by silver staining or transfer to nitrocellulose for Western blot analysis. Antibodies were polyclonal rabbit anti-ATP synthase \( \gamma \) subunit (a gift from Marie-France Giraud, Bordeaux, France), anti-Tom20 and anti-Tim54 (a gift from Nikolaus Pfanner, Freiburg, Germany).

**Electrophysiology**—Planar lipid bilayer experiments were performed as described in Ref. 31. Briefly, bilayers of 150–200 picofarads of capacitance were prepared using purified soybean asolectin. The standard experimental medium was 150 mM KC1, 10 mM Heps, pH 7.5. All reported voltages refer to the cis chamber, zero being assigned to the trans (grounded) side. Currents are considered as positive when carried by cations flowing from the cis to the trans compartment. Freshly prepared F-ATP synthase dimers were added to the cis side. No current was observed when PTP activators were added to the membrane in the absence of F-ATP synthase dimers (\( n = 2 \)).

**REPORT: Channel Formation by Yeast F-ATP Synthase**

**RESULTS AND DISCUSSION**

**Properties of the Ca\(^{2+}\)-dependent Permeability Transition of Yeast Mitochondria**—We used ETH129 to allow Ca\(^{2+}\) uptake by energized yeast mitochondria (20) and monitored the propensity of the yeast PTP to open based on the Ca\(^{2+}\) retention capacity (CRC), i.e. the maximal Ca\(^{2+}\) load retained by mitochondria before onset of the PTP (22). In keeping with previous observations (20), (i) energized yeast mitochondria were able to accumulate Ca\(^{2+}\) as a train of pulses (Fig. 1A) until onset of the PTP, which causes depolarization followed by Ca\(^{2+}\) release; and (ii) increasing concentrations of P₃ increased the matrix Ca\(^{2+}\) load necessary to open the PTP (Fig. 1, A and B), possibly following formation of matrix P₃Ca\(^{2+}\) complexes. As in mammalian mitochondria, Mg\(^{2+}\)-ADP increased the CRC, an effect consistent with PTP inhibition (Fig. 1C). The CRC was not affected by decavandate (results not shown), which inhibits the ATP-induced, voltage-dependent anion channel (VDAC)-dependent yeast permeability pathway (23, 24).

The mammalian PTP is modulated by two classes of redox-sensitive thiols whose oxidation increases the pore sensitivity to Ca\(^{2+}\), i.e. (i) matrix thiols that react with phenylarsine oxide (PhAsO) and can be oxidized by diamide (25); and (ii) external thiols that can be oxidized by copper-o-phenanthroline (Cu(OP))\(_2\) (26). The threshold Ca\(^{2+}\) load required for yPTP opening was moderately affected by PhAsO (Fig. 1D), whereas it was very sensitive to diamide (Fig. 1E) and to Cu(OP))\(_2\) (Fig. 1F). These experiments indicate that the yeast PTP is affected by the redox state of thiol groups as also suggested by a previous study (18).

CSA desensitizes the mammalian pore to Ca\(^{2+}\) through matrix CyPD, a peptidyl-protoly cis-trans isomerase that behaves as a PTP inducer (27, 28). Through studies of CyPD-null mitochondria, it became clear that CyPD is a modulator but not an obligatory constituent of the PTP and that a PT can occur in the
absence of CyPD, or in the presence of CsA, albeit at higher matrix Ca\(^{2+}\) loads (8). Yeast mitochondria possess a matrix CyP (CPR3), which facilitates folding of imported proteins in the matrix and is sensitive to CsA (29); however, the yPTP is not affected by CsA (9), as also confirmed in the CRC assay (Fig. 2A, compare traces \(a\) and \(b\)). These findings suggest either that CPR3 does not interact with the pore or that CsA does not interfere with CPR3 binding. To resolve this issue, we tested the CRC of \(\Delta CPR3\) mutants, which displayed a lower rate and slightly lower extent of Ca\(^{2+}\) accumulation (Fig. 2A, trace \(c\)), indicating that CPR3 does not sensitize the yPTP to Ca\(^{2+}\), at variance from the effects of CyPD in mammalian mitochondria (30). The small decrease of CRC in the mutants (Fig. 2B) may be due to slower protein import and defective respiratory chain assembly and/or function (31). It was recently established that rotenone is a good inhibitor of the PTP in mammalian mitochondrial protein extracts by BN-PAGE, identified dimers similar to those found in mammals (21), we separated dimers used). The addition of 1–10 pmol of the dimers to the mitochondrial protein extracts by BN-PAGE, identified dimers used). The addition of 1–10 pmol of the dimers to the

**FIGURE 1.** Properties of the permeability transition of yeast mitochondria. The incubation medium contained 250 mM sucrose, 10 mM Tris-MOPS, 1 mM NADH, 10 mM EGTA-Tris, 5 mM ETH129, 1 mM Calcium Green-SN, final pH 7.4, 0.5 mg/ml bovine serum albumin, and 0.1 mg of mitochondria in a final volume of 0.2 ml. A, the medium was supplemented with 1 mM (trace \(d\)), 2 mM (trace \(b\)), 5 mM (trace \(c\)), or 10 mM P, (trace \(d\)), and where indicated, Ca\(^{2+}\) was added. Traces shown are representative of 13 independent experiments. **A** and **B**, experimental conditions as in panel **A** with the indicated \(P_i\) concentrations. Values on the ordinate refer to the amount of Ca\(^{2+}\) accumulated prior to the precipitous release that follows the PT (n = 13 ± S.E.). C, the experimental conditions were as in panel **A** with 2 mM \(P_i\), and the medium was supplemented with 2 mM MgCl\(_2\), 1 mM oligomycin, and the stated concentrations of ADP (n = 8 ± S.E.). D–F, the experimental conditions were as in panel **A** with 2 mM \(P_i\), and the medium was supplemented with the stated concentrations of PhAsO \((D)\), diamide \((E)\), or Cu(II) \((F)\). For panels D–F, n (± S.E.) was 6, 4, and 7, respectively.

**FIGURE 2.** Purified F-ATP Synthase Dimers Possess Channel Activity—To test whether yeast F-ATP synthase dimers can form channels similar to those found in mammals (21), we separated mitochondrial protein extracts by BN-PAGE, identified dimers by in-gel activity staining, and eluted them for incorporation into a planar asolectin membrane (see Fig. 4A for an example of the dimer used). The addition of 1–10 pmol of the dimers to the bilayers in symmetrical 150 mM KCl did not elicit current activity unless Ca\(^{2+}\), PhAsO, and Cu(II) were also added (Fig. 3A). We observed a clear activity in 12 out of 14 reconstitutions, with...
channel unit conductance usually ranging between 250 and 300 pS (multiples of this unit conductance were often observed; in one case 1000 pS was reached). This conductance is compatible with the values exhibited by a channel observed in mitoplasts from a porin-less yeast strain, which was insensitive to CsA, ADP, or protons and in which the combination of ADP and Mg$^{2+}$ was not tested (33). The activity studied here was characterized by rapid oscillations between closed and open states (flickering), which is typical of the mammalian MMC-PTP, and by variable kinetics. A typical flickering behavior is illustrated in the bottom part of Fig. 3A. As is the case for the mammalian F-ATP synthase (21) and for the MMC-PTP measured in mitoplasts (4), the addition of Mg$^{2+}$-ADP induced a clear-cut inhibition of the channel in five out of six experiments (total inhibition was observed in two cases, and partial inhibition was observed in three cases). The representative experiment of Fig. 3B shows activity recorded before and immediately after the addition of Mg$^{2+}$-ADP in one case of full inhibition, which is illustrated in the corresponding amplitude histograms (Fig. 3B). Taken together, these data provide evidence that under conditions of oxidative stress, yeast F-ATP synthase can form Ca$^{2+}$-activated channels with features resembling the MMC-PTP (although with lower conductance). It should be noted that the dimer preparation did not contain Tom20 or Tim54 (Fig. 4A) and therefore that channel activity cannot be due to the twin pore translocase (34).

Dimerization of F-ATP Synthase Is Required for PTP Formation—Dimers of F-ATP synthase are the “building blocks” of long rows of oligomers located deep into the cristae, which contribute to formation of membrane curvature and to maintenance of proper cristae shape and mitochondrial morphology (35–42). Mammalian F-ATP synthase dimers also appear to be the units from which the PTP forms in a process that is highly favored by Ca$^{2+}$ and oxidative stress (21), events that are required for channel formation (8, 21). To test the hypothesis that yPTP formation requires the presence of F-ATP synthase dimers, we studied mutants lacking subunits involved in dimerization/oligomerization of the enzyme, i.e. subunit e (TIM11) and subunit g (ATP20) (35, 43–45). Strains lacking these subunits display balloon-shaped cristae with ATP synthase monomers distributed randomly in the membrane (39). The ΔTIM11, ΔATP20, and ΔTIM11ΔATP20 mutants lacked dimers when analyzed by BN-PAGE, whereas the monomeric F-ATP synthase was assembled and active (Fig. 4A), consistent with their ability to grow on non-fermentable carbon sources, and developed a normal membrane potential upon energization with NADH (results not shown). CRC assays with ETH129 demonstrated that mitochondria from ΔTIM11, ΔATP20, and ΔTIM11ΔATP20 strains take up a larger Ca$^{2+}$ load than wild-type strains (Fig. 4B), with a doubling of the CRC (Fig. 4C).

Dimers may transiently form also in ΔTIM11 and ΔATP20 strains (46), a finding that could explain why Ca$^{2+}$ release is eventually observed also in the “dimerization-less” mutants. Consistent with this possibility, we did detect dimers in BN-PAGE after treatment with CuCl$_2$ (Fig. 4D), which promotes formation of disulfide bridges between adjacent cysteine residues of the monomers (45, 47, 48). Not all of the monomers dimerized after CuCl$_2$ treatment (Fig. 4D), suggesting that cysteine oxidation stabilizes pre-existing dimers that are otherwise
dissociated by detergent treatment, but does not induce cross-linking of monomers.

In summary, our data provide the first demonstration that yeast F-ATP synthase dimers form high conductance channels analogous to the mammalian MMC-PTP, and thus that channel formation is a conserved feature of F-ATP synthases; show that yeast mitochondria can undergo a bona fide PT activation by oxidative stress; and indicate that dimers of F-ATP synthase that yeast mitochondria can undergo a
nel formation is a conserved feature of F-ATP synthases; show analogous to the mammalian MMC-PTP, and thus that chan-

yeast F-ATP synthase dimers form high conductance channels linking of monomers.

In summary, our data provide the first demonstration that yeast F-ATP synthase dimers form high conductance channels analogous to the mammalian MMC-PTP, and thus that channel formation is a conserved feature of F-ATP synthases; show that yeast mitochondria can undergo a bona fide PT activation by oxidative stress; and indicate that dimers of F-ATP synthase are required for PTP formation in situ (21). Our findings do not exclude the existence of other permeability pathways that may involve the voltage-dependent anion channel (23, 24), nor the possible regulation of yPTP by outer mitochondrial membrane proteins (8). We think that it will now be possible to unravel the many open questions about the structure and function of the PTP (8) with the powerful methods of yeast genetics.

Acknowledgments—We thank Marie-France Giraud and Nikolaus Pfanner for the generous gift of antibodies and Raffaele Lopreiato for advice on the preparation of mutants.
