October 7, 1997

Abstract

Multiplication of two elements of the special unitary group $SU(N)$ determines uniquely a third group element. A Baker-Campbell-Hausdorff relation is derived which expresses the group parameters of the product (written as an exponential) in terms of the parameters of the exponential factors. This requires the eigenvalues of three $(N \times N)$ matrices. Consequently, the relation can be stated analytically up to $N = 4$, in principle. Similarity transformations encoding the time evolution of quantum mechanical observables, for example, can be worked out by the same means.

1 Introduction

Various questions in physics reduce to the following problem: write the product of exponential functions depending on noncommuting operators \hat{A} and \hat{B} , respectively, as the exponential of a third operator, \hat{C} ,

$$\exp[\hat{A}] \exp[\hat{B}] = \exp[\hat{C}]. \quad (1)$$

The names of Baker, Campbell, and Hausdorff (BCH) are associated (cf. [21]) with a formula for the operator \hat{C} expressed in multiple commutators of \hat{A} and \hat{B} :

$$\hat{C} = \hat{A} + \hat{B} + \frac{1}{2}[\hat{A}, \hat{B}] + \frac{1}{12}([\hat{A}, [\hat{A}, \hat{B}]] + [[\hat{A}, \hat{B}], \hat{B}]) + \dots \quad (2)$$

Remarkably, the operator \hat{C} is expressed depends on commutators of \hat{A} and \hat{B} *only* implying that it is contained in the same algebra as \hat{A} and \hat{B} . For this result to hold it is crucial to consider products of *exponential* functions.

Although the expansion (2) for the operator \hat{C} is explicit, usually the infinite series of repeated commutators cannot be summed in closed form. It may be

used, however, to generate an approximate expression for \widehat{C} by directly calculating a finite number of terms [8]. When read from left to right, Eq. (1) shows how to *entangle* the two factors into a single exponential. An application important in quantum mechanics results for the Heisenberg group of position and momentum operators \hat{q} and \hat{p} , where

$$\exp[-i\hat{p}]\exp[-i\hat{q}] = \exp[-i(\hat{p} + \hat{q}) + i\hbar/2]. \quad (3)$$

The right-hand-side is particularly simple because the commutator

$$[\hat{p}, \hat{q}] = \frac{\hbar}{i} \quad (4)$$

is a constant such that only the first commutator in (2) contributes to the operator \widehat{C} . Another situation with the need for entangling two operators is encountered in periodically driven systems. In specific cases, the propagator over one full period reduces to a product of the propagators for shorter intervals [4, 7, 19]. The Lie algebras involved in these ‘quantum maps’ may either have a finite or an infinite number of elements.

When read in the opposite sense, Eq. (1) represents a *disentangling* relation, that is, the decomposition of a single exponential into factors with simple properties. Such a relation is useful to calculate expectation values of basic operators in the group $SU(2)$, for example, since they are easily derived from a generating function in disentangled form [1]. Similarly, changes of the group parameterization [9] are conveniently performed by using BCH-relations. In general, the discussion of coherent states for particle and spin systems as well as for arbitrary Lie groups [16] benefits from the knowledge of (de-)composition rules (1).

A closely related question arises from the need to perform similarity transformations according to

$$\exp[-\widehat{A}]\widehat{B}\exp[\widehat{A}] = \widehat{B}'. \quad (5)$$

If the operator \widehat{A} is proportional to i times the Hamiltonian of a quantum system, Eq. (5) describes the time evolution of the Heisenberg observable \widehat{B} into \widehat{B}' .

A number of techniques has been established in order to efficiently treat entangling and disentangling problems, in particular, if the operators involved in the BCH-relation are elements of a *finite*-dimensional Lie algebra. Two-dimensional unitary faithful irreducible representations are used to derive explicit results for the group $SU(2)$ [9], and for the group of the harmonic oscillator [15, 10], for example. Applications to more complicated cases involving symplectic groups also have been worked out in detail [20, 11]. However, it is *not* necessary to exclusively work with unitary representations: any faithful representation can be used [10]. This is helpful if one knows a representation

consisting of upper and lower triangular matrices since they are easily exponentiated. Disentanglement of Lie group elements is also achieved by using recursion relations for expanded exponentials and Laplace-transform techniques [18]. This approach generalizes a method first applied to particular group elements of $SU(3)$ [17]. The powerful approach in [21] maps the problem of both (dis-)entangling (1) and similarity (5) transformations to the solution of a set of coupled first-order differential equations. This paper also contains theoretical background on BCH-relations, applications in physics as well as a large number of references.

In the present paper a different method to evaluate BCH-relations is developed for the groups $SU(N)$. It is based on the spectral theorem for hermitian operators in finite-dimensional vector spaces. A ‘linearized’ version of this result is derived by exploiting a specific feature of the algebra $su(N)$ going beyond its Lie algebraic properties. In this way, a one-to-one correspondence between an exponential of linearly combined generators and a linear combination of them is established – ‘removing’ thus the exponential function. It is then straightforward to entangle elements of the group $SU(N)$. Conceptually, this method is related to work performed in the early 1970’s where the study of chiral algebras required the evaluation of *finite* transformations for special unitary groups [2, 3]. In that context, however, BCH-relations have not been considered.

2 Some Fundamentals of $SU(N)$

An irreducible faithful representation of the group $SU(N)$ [14] is given by the set of all unitary ($N \times N$) matrices U with unit determinant,

$$\det U = 1, \quad U_{nn'} \in \mathbf{C}, \quad n, n' = 1, \dots, N. \quad (6)$$

Each matrix U can be written in the form

$$U = \exp[-iL], \quad L^\dagger = L, \quad (7)$$

with a traceless hermitian matrix L . It is conveniently expressed as a linear combination

$$L = \vec{L} \cdot \vec{\Lambda} \equiv \sum_{j=1}^{N^2-1} L_j \Lambda_j, \quad L_j \in \mathbf{R}, \quad (8)$$

with the set $\vec{\Lambda}$ forming a basis for traceless hermitian matrices, $\Lambda_j^\dagger = \Lambda_j$, called the generators. At the same time, they are a basis of the Lie *algebra* $su(N)$ of $SU(N)$, satisfying the commutation relations:

$$[\Lambda_j, \Lambda_k]_- = 2if_{jkl}\Lambda_l, \quad (9)$$

where the indices j, k, l , take values from 1 to $N^2 - 1$, the summation convention for repeated indices applies, and the ($N \times N$) unit matrix is denoted by 1_N .

The structure constants f_{jkl} are elements of a completely antisymmetric tensor (spelled out explicitly in [12], for example) with Jacobi identity

$$f_{klm}f_{mpq} + f_{plm}f_{mkq} + f_{kpm}f_{mlq} = 0. \quad (10)$$

The group $SU(N)$ has rank $(N - 1)$. In other words, any maximal abelian subalgebra of $su(N)$ consists of $(N - 1)$ elements corresponding to all linearly independent traceless N -dimensional diagonal matrices. A ‘complete set of commuting variables’ for a quantum system described by $SU(N)$ would contain in addition the same number of Casimir operators according to Racah’s theorem [12].

A particular feature of the algebra $su(N)$ is its closure under *anti* commutation of its elements:

$$[\Lambda_j, \Lambda_k]_+ = \frac{4}{N} \delta_{jk} \mathbf{1}_N + 2d_{jkl} \Lambda_l, \quad (11)$$

where the d_{jkl} form a totally symmetric tensor (cf. [12]). For $N = 2$, *all* numbers d_{jkl} are equal to zero, and the generators $\vec{\Lambda}$ coincide with the Pauli matrices $\vec{\sigma}$: the anticommutator of two of them is either equal to zero or a multiple of the unit matrix, $\mathbf{1}_2$.

The anticommutation relation will be important in the present context but it is *not* generic for an arbitrary Lie algebra. As a consequence of (11), two generators Λ_j and Λ_k of $su(N)$ are ‘orthogonal’ to each other with respect to the trace:

$$\text{Tr}(\Lambda_j \Lambda_k) = 2\delta_{jk}. \quad (12)$$

In addition, a second Jacobi-type identity exists involving both the antisymmetric and the symmetric structure coefficients in (9) and (11):

$$f_{klm}d_{mpq} + f_{kqm}d_{mpl} + f_{kpm}d_{mlq} = 0. \quad (13)$$

For the following, a vector-type notation is useful, based on the structure constants and the Kronecker symbol. Define the scalar product as employed already in Eq. (8),

$$\vec{A} \cdot \vec{B} = A_n \delta_{nm} B_m = A_n B_n, \quad (14)$$

where the components of \vec{A} and \vec{B} are allowed to be either numbers or generators Λ_n . Similarly, define an antisymmetric ‘cross product’ \otimes by

$$(\vec{A} \otimes \vec{B})_j = f_{jkl} A_k B_l = -(\vec{B} \otimes \vec{A})_j, \quad (15)$$

and a symmetric ‘dot product’ \odot :

$$(\vec{A} \odot \vec{B})_j = d_{jkl} A_k B_l = +(\vec{B} \odot \vec{A})_j. \quad (16)$$

Then, the relations (9,11) can be written

$$\left[\vec{A} \cdot \vec{\lambda}, \vec{B} \cdot \vec{\lambda} \right]_- = 2i(\vec{A} \otimes \vec{B}) \cdot \vec{\lambda}, \quad (17)$$

$$\left[\vec{A} \cdot \vec{\lambda}, \vec{B} \cdot \vec{\lambda} \right]_+ = \frac{4}{N} \vec{A} \cdot \vec{B} \mathbb{1}_N + 2(\vec{A} \odot \vec{B}) \cdot \vec{\lambda}, \quad (18)$$

where \vec{A} and \vec{B} are *arbitrary* vectors of dimension $(N^2 - 1)$ with numeric entries. Adding these equations leads to a compact form of the (anti-) commutation relations:

$$(\vec{A} \cdot \vec{\lambda})(\vec{B} \cdot \vec{\lambda}) = \frac{2}{N} \vec{A} \cdot \vec{B} \mathbb{1}_N + (\vec{A} \odot \vec{B} + i\vec{A} \otimes \vec{B}) \cdot \vec{\lambda}. \quad (19)$$

This equation emphasizes the important point that any expression *quadratic* in the generators can be expressed as a *linear* combination of them, including the identity. As a matter of fact, it generalizes the known identity in $SU(2)$ for the Pauli matrices:

$$(\vec{A} \cdot \vec{\sigma})(\vec{B} \cdot \vec{\sigma}) = \vec{A} \cdot \vec{B} \mathbb{1}_N + i\vec{A} \otimes \vec{B} \cdot \vec{\sigma}. \quad (20)$$

In the new notation, the identities (10,13) read

$$(\vec{A} \otimes \vec{B}) \cdot (\vec{C} \otimes \vec{D}) + (\vec{C} \otimes \vec{B}) \cdot (\vec{A} \otimes \vec{D}) + (\vec{A} \otimes \vec{C}) \cdot (\vec{B} \otimes \vec{D}) = 0, \quad (21)$$

$$(\vec{A} \otimes \vec{B}) \cdot (\vec{C} \odot \vec{D}) + (\vec{A} \otimes \vec{D}) \cdot (\vec{C} \odot \vec{B}) + (\vec{A} \otimes \vec{C}) \cdot (\vec{B} \odot \vec{D}) = 0. \quad (22)$$

Another useful form of Eq. (13) is given by

$$\vec{A} \otimes (\vec{B} \odot \vec{C}) = (\vec{A} \otimes \vec{B}) \odot \vec{C} + \vec{B} \odot (\vec{A} \otimes \vec{C}), \quad (23)$$

showing that applying $\vec{A} \otimes$ to a \odot product acts as does a derivative. The ‘orthogonality’ of the generators (12) becomes

$$\text{Tr} \left((\vec{A} \cdot \vec{\lambda})(\vec{B} \cdot \vec{\lambda}) \right) = 2\vec{A} \cdot \vec{B}, \quad (24)$$

for arbitrary \vec{A} and \vec{B} .

3 Spectral theorem

Every matrix $\mathbf{M} \in \mathbf{C}^N$ satisfies its own characteristic equation,

$$\sum_{n=0}^N a_n \mathbf{M}^n = 0 \quad a_N = 1, a_0 = \det \mathbf{M}, \quad (25)$$

according to the theorem of Cayley-Hamilton. The coefficients a_n define the characteristic polynomial of \mathbf{M} . For traceless matrices such as $\mathbf{M} \in su(N)$, the coefficient a_{N-1} in Eq. (25) is equal to zero since it equals the trace of \mathbf{M} .

According to Eq. (25), any power $N' \geq N$ of the matrix \mathbf{M} is identical to a linear combination of its powers \mathbf{M}^n with $0 \leq n \leq N - 1$. The expansion of a matrix exponential can thus be written

$$\exp[-i\mathbf{M}] = \sum_{m=0}^{\infty} \frac{(-i\mathbf{M})^m}{m!} = \sum_{n=0}^N e_n(\mathbf{M})\mathbf{M}^n, \quad (26)$$

with uniquely defined coefficients $e_n(\mathbf{M})$. They are determined directly by referring to the *spectral theorem* [13] valid for smooth functions f of a hermitian matrix \mathbf{M} with (nondegenerate) eigenvalues m_k , $k = 1, \dots, N$:

$$f(\mathbf{M}) = \sum_{k=1}^N f(m_k)\mathbf{P}_k, \quad (27)$$

and the operator $\mathbf{P}_k = |m_k\rangle\langle m_k|$ projects down to the one-dimensional eigenspace spanned by the eigenvector $|m_k\rangle$ associated with the eigenvalue m_k . In terms of powers \mathbf{M}^k and the eigenvalues m_k , the matrices \mathbf{P}_k read

$$\mathbf{P}_k = \prod_{n \neq k} \frac{\mathbf{M} - m_n}{m_k - m_n} = \sum_{n=0}^{N-1} P_{kn}\mathbf{M}^n; \quad (28)$$

the sum contains powers \mathbf{M}^{N-1} at most since the product runs over $(N - 1)$ factors. Combining Eqs. (27) and (28), one obtains that

$$f(\mathbf{M}) = \sum_{n=0}^{N-1} \left(\sum_{k=1}^N P_{kn}f(m_k) \right) \mathbf{M}^n \equiv \sum_{n=0}^{N-1} f_n \mathbf{M}^n, \quad (29)$$

and, upon choosing $f(x) \equiv \exp(-ix)$, the sum in the round brackets produces the coefficients e_n of the expansion (26) in terms of the eigenvalues m_k .

It is possible [18] to express the numbers f_n in (29) differently. Write the coefficient $f_{N-1}(\mathbf{M}, \lambda)$ of \mathbf{M}^{N-1} with a dummy parameter λ introduced as follows:

$$f_{N-1}(\mathbf{M}, \lambda) = \sum_{n=1}^N \Delta_n f(\lambda m_n), \quad \Delta_n = \prod_{k \neq n} (m_n - m_k)^{-1}. \quad (30)$$

Linear combinations of derivatives with respect to λ yield the remaining coefficients f_n , $n = 0, 1, \dots, N - 2$, associated with any smooth function f :

$$f_n(\mathbf{M}) = \left[\left(\partial_{\lambda}^{N-n-1} - \sum_{\nu=1}^{N-n-1} a_{N-\nu} \partial_{\lambda}^{N-n-1-\nu} \right) f_{N-1}(\mathbf{M}, \lambda) \right]_{\lambda=1}, \quad (31)$$

with numbers a_n from the characteristic polynomial (25), and the abbreviation $d/d\lambda \equiv \partial_{\lambda}$. Since Eq. (29) requires the eigenvalues of \mathbf{M} , analytic expressions will be obtained only for (4×4) matrices at most, i.e. for $SU(4)$.

4 Linearized spectral theorem

A stronger version of relation (27) is derived now. It is valid for hermitian $(N \times N)$ matrices, and it will be called the *linearized spectral theorem*:

$$f(\vec{M} \cdot \vec{\Lambda}) = f_0(\vec{M})1_N + \vec{f}(\vec{M}) \cdot \vec{\Lambda}. \quad (32)$$

It states that any function f of a linear combination of the generators $\vec{\Lambda}$ of $SU(N)$ is equal to a linear combination of the identity and the generators with well-defined coefficients (f_0, \vec{f}) . In other words, the powers of the generators $\vec{\Lambda}$ contained in the powers $\mathbf{M}^n \equiv (\vec{M} \cdot \vec{\Lambda})^n$ in Eq. (29) can be reduced to linear combinations of them. In view of the commutation relations of the algebra $su(N)$, Eq. (19), this is not surprising: the required reduction is carried out in a finite number of steps by repeatedly expressing products of two generators by a linear combination of generators.

A convenient procedure to determine (f_0, \vec{f}) in (32) starts from writing

$$\mathbf{M}^n = \mu_{0,n} 1_N + \vec{\mu}_n \cdot \vec{\Lambda}, \quad n = 0, 1, 2, \dots, N-1, \quad (33)$$

where

$$\mu_{0,0} = 1, \quad \mu_{0,1} = 0, \quad (34)$$

$$\vec{\mu}_0 = 0, \quad \vec{\mu}_1 = \vec{M}. \quad (35)$$

A recursion relation for $(\mu_{0,n}, \vec{\mu}_n)$ follows from writing $\mathbf{M}^{n+1} = \mathbf{M}^n \mathbf{M}$, using (19) and (33),

$$\begin{aligned} \mathbf{M}^{n+1} &= \mu_{0,n} \vec{M} \cdot \vec{\Lambda} + (\vec{\mu}_n \cdot \vec{\Lambda})(\vec{M} \cdot \vec{\Lambda}) \\ &= \frac{2}{N} \vec{\mu}_n \cdot \vec{M} 1_N + (\mu_{0,n} \vec{M} + \vec{\mu}_n \odot \vec{M} + i \vec{\mu}_n \otimes \vec{M}) \cdot \vec{\Lambda}. \end{aligned} \quad (36)$$

Comparison with (33) for $(n+1)$ instead of n shows that

$$\mu_{0,n+1} = \frac{2}{N} \vec{\mu}_n \cdot \vec{M}, \quad (37)$$

$$\vec{\mu}_{n+1} = \mu_{0,n} \vec{M} + \vec{\mu}_n \odot \vec{M} + i \vec{\mu}_n \otimes \vec{M} = \frac{2}{N} (\vec{\mu}_{n-1} \cdot \vec{M}) \vec{M} + \vec{\mu}_n \odot \vec{M}, \quad (38)$$

which recursively defines $(\mu_{0,n}, \vec{\mu}_n)$ in terms of \vec{M} , starting with the ‘initial values’ (34,35). The terms $i \vec{\mu}_n \otimes \vec{M}$ do *not* contribute since each $\vec{\mu}_n$ following from (33) is proportional to $\vec{M}, \vec{M} \odot \vec{M}, (\vec{M} \odot \vec{M}) \odot \vec{M}, \dots$. Using the derivative-like property (23), one always encounters terms $\vec{M} \otimes \vec{M}$ being equal to zero. Consequently, the coefficients (f_0, \vec{f}) on the right-hand-side of (32) have been expressed explicitly through \vec{M} and the eigenvalues m_k :

$$f_0(\vec{M}) = \sum_{n=0}^{N-1} f_n \mu_{0,n}, \quad \vec{f}(\vec{M}) = \sum_{n=0}^{N-1} f_n \vec{\mu}_n, \quad (39)$$

with f_n from Eqs. (30) and (31). Note that according to (38) the expression for $\vec{f}(\vec{M})$ contains only totally symmetric powers $\vec{M}, \vec{M} \odot \vec{M}, (\vec{M} \odot \vec{M}) \odot \vec{M}, \dots$. Given \vec{M} , a simple expression for f_0 is provided by taking the trace of Eq. (32):

$$f_0(\vec{M}) = \frac{1}{N} \text{Tr}(f(\vec{M} \cdot \vec{\Lambda})) = \frac{1}{N} \sum_{k=1}^N f(m_k). \quad (40)$$

It should be pointed out that f_0 is *not* independent of \vec{f} : one can solve the recursion for $\vec{\mu}_n$, Eq. (38) without referring to (37). This is reasonable because only then one has the *same* number of parameters in \vec{M} and on the right-hand-side of (32).

Suppose now that the *right-hand-side* of Eq. (32) is given, i.e. the parameters (f_0, \vec{f}) are known to define a group element of $SU(N)$. How does one express \vec{M} in terms of \vec{f} ? This is actually the difficult step when deriving a BCH-formula: to find the group element in terms of the the original parametrization. Assume the function f to be invertible, then one can write

$$\vec{M} \cdot \vec{\Lambda} = f^{-1}(f_0 \mathbb{1}_N + \vec{f} \cdot \vec{\Lambda}) = F(\vec{f} \cdot \vec{\Lambda}) \quad (41)$$

with a new function F . The clue to the inversion is to realize that (41) represents an equation of the type (32) again. This follows from reading Eq. (32) from right to left, replacing $f \rightarrow F$, exchanging the role of \vec{f} and \vec{M} , and setting f_0 equal to zero in (32). Now the reasoning leading to Eq. (39) can be repeated in order to determine $\vec{M} = \vec{M}(\vec{f})$. Therefore, \vec{M} can be found as a function of \vec{f} by the means already established.

The orthonormality (12) for the generators $\vec{\Lambda}$ allows one to formally switch from \vec{M} to \vec{f} and *vice versa* in a simple manner: multiply Eq. (32) with Λ_k and take the trace which leads to

$$f_k = \text{Tr} \left(f_0 \Lambda_k + \vec{f} \cdot \vec{\Lambda} \Lambda_k \right) = \text{Tr} \left(f(\vec{M} \cdot \vec{\Lambda}) \Lambda_k \right), \quad (42)$$

while the inverse transformation follows from (41):

$$M_k = \text{Tr} \left((\vec{M} \cdot \vec{\Lambda}) \Lambda_k \right) = \text{Tr} \left(f^{-1}(f_0 \mathbb{1}_N + \vec{f} \cdot \vec{\Lambda}) \Lambda_k \right). \quad (43)$$

Before applying the linearized spectral theorem to the derivation of BCH-formulae, a comment on the relation between the matrices $\mathbf{M} = \vec{M} \cdot \vec{\Lambda}$ and \mathbf{F} in (32),

$$f(\mathbf{M}) = f_0 \mathbb{1}_N + \mathbf{F} \quad (44)$$

should be made. One must have $[\mathbf{M}, \mathbf{F}] = 0$ since Eq. (44) is an identity. Nevertheless, the matrices involved do not have to be multiples of each other. The vanishing commutator implies that the matrices \mathbf{M} and \mathbf{F} can be diagonalized simultaneously. Having done this \mathbf{M} would be given by a specific linear combination of $(n-1)$ traceless diagonal generators $\mathbf{H}_k, k = 1, 2, \dots, N-1$. The

matrix F commutes with M and it is therefore only required to be another element of the maximal abelian subalgebra containing M . For the group $SU(2)$, the dimension of this algebra is equal to one: M and F are in this (and only this) case proportional to each other (cf. the first example below). For $SU(3)$ this observation is illustrated by a result of [6] where Lie groups are studied from a geometric point of view. In an appropriate local basis, any group element can be written as a function of a linear combination of two commuting operators which span a maximal abelian subalgebra.

5 BCH for $SU(N)$

A Baker-Campbell-Hausdorff relation for composing of group elements of $SU(N)$ follows from twofold application of the linearized spectral theorem with $f(x) = \exp[-ix]$. Consider the product of two finite transformations, $\exp[-i\vec{M} \cdot \vec{\Lambda}]$ and $\exp[-i\vec{N} \cdot \vec{\Lambda}]$, which defines a third element of $SU(N)$ characterized by \vec{R} ,

$$\exp[-i\vec{R} \cdot \vec{\Lambda}] = \exp[-i\vec{M} \cdot \vec{\Lambda}] \exp[-i\vec{N} \cdot \vec{\Lambda}]. \quad (45)$$

Using Eq. (32) with the exponential function, one obtains

$$\begin{aligned} \exp[-i\vec{R} \cdot \vec{\Lambda}] &= \mu_0 \nu_0 \mathbb{1}_N + (\nu_0 \vec{\mu} + \mu_0 \vec{\nu}) \cdot \vec{\Lambda} + (\vec{\mu} \cdot \vec{\Lambda})(\vec{\nu} \cdot \vec{\Lambda}) \\ &= (\mu_0 \nu_0 + \frac{2}{N} \vec{\mu} \cdot \vec{\nu}) \mathbb{1}_N + (\nu_0 \vec{\mu} + \mu_0 \vec{\nu} + \vec{\mu} \odot \vec{\nu} + i \vec{\mu} \otimes \vec{\nu}) \cdot \vec{\Lambda} \\ &= \rho_0 \mathbb{1}_N + \vec{\rho} \cdot \vec{\Lambda}, \end{aligned} \quad (46)$$

using the commutation relations (19). The quantities $(\rho_0, \vec{\rho})$ can be read off directly as the coefficients of $\mathbb{1}_N$ and Λ_j , respectively. The components of \vec{R} are thus given by Eq. (43):

$$\begin{aligned} R_k &= i \operatorname{Tr} \left\{ \ln \left[(\mu_0 \nu_0 + \frac{2}{N} \vec{\mu} \cdot \vec{\nu}) \mathbb{1}_N \right. \right. \\ &\quad \left. \left. + (\nu_0 \vec{\mu} + \mu_0 \vec{\nu} + \vec{\mu} \odot \vec{\nu} + i \vec{\mu} \otimes \vec{\nu}) \cdot \vec{\Lambda} \right] \Lambda_k \right\}, \end{aligned} \quad (47)$$

providing the relation $\vec{R} = \vec{R}(\vec{M}, \vec{N})$. The explicit evaluation requires diagonalization of the matrices M and N in order to determine $\vec{\mu}$ and $\vec{\nu}$; finally, $\vec{\rho} \cdot \vec{\Lambda}$ has to be diagonalized in order to get rid of the logarithm in Eq. (47). In total, three $(N \times N)$ matrices have to be diagonalized to achieve the entangling.

As an illustration, the familiar example of $SU(2)$ will be looked at from the point of view developed here. However, the \odot product being identical to zero, this case does not exhibit the full complexity. Therefore, $SU(4)$ will also be discussed briefly. Before giving the examples, the use of the linearized spectral theorem for the determination of similarity transformations in the group $SU(N)$ will be indicated.

6 Similarity transformations

The transformation of the operator $\mathbf{N} = \vec{N} \cdot \vec{\Lambda} \in su(N)$ under $\mathbf{M} = \vec{M} \cdot \vec{\Lambda} \in su(N)$ according to

$$\exp[-i\mathbf{M}] \mathbf{N} \exp[i\mathbf{M}] = \mathbf{N}' \quad (48)$$

could be determined from the linearized spectral theorem in the following way. Write the group element as

$$\exp[i\mathbf{M}] = \mu_0 \mathbf{1}_N + \vec{\mu} \cdot \vec{\Lambda}, \quad (49)$$

and its inverse follows from the adjoint of this equation as

$$\exp[-i\mathbf{M}] = \mu_0^* \mathbf{1}_N + \vec{\mu}^* \cdot \vec{\Lambda}, \quad (50)$$

where the star denotes complex conjugation. Plugging these expressions into (48), one encounters triple products of generators $\vec{\Lambda}$ which when reduced to a linear combination lead to a somewhat involved expression. It is more convenient to first multiply Eq. (48) with $\exp[i\mathbf{M}]$, and to work out the terms *quadratic* in the generators. Comparison of the coefficients of $\mathbf{1}_N$ and $\vec{\Lambda}$ leads to

$$\vec{\mu} \cdot \vec{\nu} = \vec{\mu} \cdot \vec{N}', \quad (51)$$

$$\mu_0 \vec{N} + \vec{N} \odot \vec{\mu} + i \vec{N} \otimes \vec{\mu} = \mu_0 \vec{N}' + \vec{\mu} \odot \vec{N}' + i \vec{\mu} \otimes \vec{N}'. \quad (52)$$

It is the vector \vec{N}' which must be determined from these equations. It is useful to rewrite Eq. (52) with matrices

$$\mathbf{K}_{\pm} \equiv \mu_0 \mathbf{1}_N + \vec{\mu} \odot \pm i \vec{\mu} \otimes, \quad (53)$$

acting on the vectors \vec{N} and \vec{N}' , respectively,

$$\mathbf{K}_- \vec{N} = \mathbf{K}_+ \vec{N}'. \quad (54)$$

The matrix \mathbf{K}_+ *does* have an inverse, \mathbf{K}_+^{-1} , since it describes the action of $\exp[i\mathbf{M}]$ on \mathbf{N}' which *is* invertible. Consequently, the vector \vec{N}' is determined by the relation

$$\begin{aligned} \vec{N}' &= \mathbf{K}_+^{-1} \mathbf{K}_- \vec{\nu} \\ &= (\mu_0 \mathbf{1}_N + \vec{\mu} \odot + i \vec{\mu} \otimes)^{-1} (\mu_0 \mathbf{1}_N + \vec{\mu} \odot - i \vec{\mu} \otimes) \vec{N}, \end{aligned} \quad (55)$$

as a function of $\vec{\mu}$ and \vec{N} as required.

7 Example 1: $SU(2)$

The group $SU(2)$ is used to describe rotations in quantum mechanics and it is isomorphic [5, 9] to the group of unimodular quaternions, $Sl(1, q)$. The multiplication rules of quaternions being known, explicit expressions for the product of two elements of the group $SU(2)$ are obtained easily. In quantum mechanics, as a first step one usually establishes the relation

$$\exp[-i\vec{\alpha} \cdot \vec{\sigma}/2] = \cos(\alpha/2) \mathbb{1}_2 - i \sin(\alpha/2) \vec{e}_\alpha \cdot \vec{\sigma}, \quad (56)$$

$$\vec{\alpha} = \alpha \vec{e}_\alpha, \quad \vec{e}_\alpha \cdot \vec{e}_\alpha = 1, \quad (57)$$

by an expansion (26) of the exponential exploiting the simple properties of the (2×2) Pauli matrices. The three-vector $\vec{\alpha}$ determines both the axis of rotation, \vec{e}_α , and the turning angle, $0 \leq \alpha \leq 4\pi$. Eq. (57) is special since the matrix in the exponent and the second term on the right are proportional to each other. As was mentioned before this is due to the fact that the group $SU(2)$ has rank one, implying that all traceless (2×2) matrices are multiples of each other. Working out the product of two rotations characterized by $\vec{\alpha}$ and $\vec{\beta}$, respectively, one obtains

$$\begin{aligned} \exp[-i\vec{\gamma} \cdot \vec{\sigma}/2] &= \left(\cos(\alpha/2) \cos(\beta/2) + \vec{\alpha} \cdot \vec{\beta} \right) \mathbb{1}_2 \\ &\quad - i \left(\sin(\alpha/2) \cos(\beta/2) \vec{e}_\alpha + \cos(\alpha/2) \sin(\beta/2) \vec{e}_\beta \right. \\ &\quad \left. + \sin(\alpha/2) \sin(\beta/2) \vec{e}_\alpha \times \vec{e}_\beta \right) \cdot \vec{\sigma}. \end{aligned} \quad (58)$$

The vector $\vec{\gamma}$ which points along the axis of the composed rotation can be read off directly.

Eqs. (57) and (58) are derived easily from the spectral method. First, write down the quantities introduced in the derivation of Eq. (39). The spectral theorem (32) involves the projection operators P_\pm (with $(\pm) \equiv (1, 2)$) which for $SU(2)$ are found from (28) to be

$$P_\pm = \frac{\vec{\alpha} \cdot \vec{\sigma} - \alpha_\mp}{\alpha_\pm - \alpha_\mp} = \frac{1}{2} (\mathbb{1}_2 \pm \vec{e}_\alpha \cdot \vec{\sigma}), \quad (59)$$

using that the operator $\vec{\alpha} \cdot \vec{\sigma}$ has eigenvalues $\alpha_\pm = \pm\alpha$. This immediately reproduces Eq. (57) via

$$e^{-i\alpha_+ P_+} + e^{-i\alpha_- P_-} = \exp[-i\vec{\alpha} \cdot \vec{\sigma}/2]. \quad (60)$$

Writing down the right-hand-side of Eq. (46) for the parameters $(\mu_0 = \cos(\alpha/2), \vec{\mu} = -\sin(\alpha/2)\vec{e}_\alpha)$ and similarly for $(\nu_0, \vec{\nu})$, one finds that (keep $\odot \equiv 0$ in mind)

$$\gamma_0 = \cos(\alpha/2) \cos(\beta/2) + \sin(\alpha/2) \sin(\beta/2) \vec{e}_\alpha \cdot \vec{e}_\beta, \quad (61)$$

$$\begin{aligned} \vec{\gamma} &= (\cos(\beta/2) \sin(\alpha/2) \vec{e}_\alpha + \cos(\alpha/2) \sin(\beta/2) \vec{e}_\beta \\ &\quad + \sin(\alpha/2) \sin(\beta/2) \vec{e}_\alpha \otimes \vec{e}_\beta) \cdot \vec{\sigma}. \end{aligned} \quad (62)$$

This reproduces indeed Eq. (58) because \otimes coincides with the familiar cross product in three dimensions. Note that the results have been derived here without explicitly expanding the exponentials involved.

8 Example 2: $SU(4)$

The example of $SU(2)$ is exceptional in the sense that (i) the product \odot is identically zero, (ii) the spectral theorem and its linearized version coincide, and (iii) the matrices \mathbf{M} and \mathbf{F} in Eq. (44) are multiples of each other. None of these properties holds for $SU(N)$, $N \geq 3$, all of which do provide *generic* examples to illustrate the BCH-composition rule. Analytic solvability of the third- and fourth-order characteristic polynomials is a pleasant accident but it does not have any structural consequences in the present context. To give a nontrivial example, $SU(4)$ will be studied below.

The interesting point is the reduction of the spectral theorem for an element of $SU(4)$ to linear form. Let us assume that the coefficients $e_n(\vec{M})$ of the powers of \mathbf{M} in Eq. (26) have been determined (use $f(x) \equiv \exp[-ix]$) by solving the characteristic polynomial of \mathbf{M} and employing Eqs. (30) and (31):

$$\begin{aligned} \exp[-i\mathbf{M}] &= e_0 \mathbf{1}_4 + e_1 \vec{M} \cdot \vec{\Lambda} + e_2 (\vec{M} \cdot \vec{\Lambda})^2 + e_3 (\vec{M} \cdot \vec{\Lambda})^3 \\ &= \left(e_1 + e_2 \frac{1}{2} \vec{M}^2 + e_3 \frac{1}{2} (\vec{M} \odot \vec{M}) \cdot \vec{M} \right) \mathbf{1}_4 \\ &\quad + \left((e_1 + e_3 \frac{1}{2} \vec{M}^2) \vec{M} + e_2 \vec{M} \odot \vec{M} + e_3 (\vec{M} \odot \vec{M}) \odot \vec{M} \right) \cdot \vec{\Lambda}, \end{aligned} \quad (63)$$

and that the reduction has been carried out via Eq. (19), using the antisymmetry of the \otimes product. Alternatively, one employs formula (39) based on the recursion relations. The quadratic and cubic terms lead to vectors with third powers of \vec{M} at most. As an identity, left- and right-hand-side of (63) must commute which is not trivial only for the last two terms multiplying $\vec{\Lambda}$:

$$[\vec{M} \cdot \vec{\Lambda}, (\vec{M} \odot \vec{M}) \cdot \vec{\Lambda}] = 2i \{ \vec{M} \otimes (\vec{M} \odot \vec{M}) \} \cdot \vec{\Lambda} = 0, \quad (64)$$

as follows from (22) applied to the quantity in curly brackets. Similarly, for the fourth term one finds

$$[\vec{M} \cdot \vec{\Lambda}, \{ (\vec{M} \odot \vec{M}) \odot \vec{M} \} \cdot \vec{\Lambda}] = 2i \left(\vec{M} \otimes \{ (\vec{M} \odot \vec{M}) \odot \vec{M} \} \right) \cdot \vec{\Lambda} = 0, \quad (65)$$

Furthermore, one shows along the same line that these two terms commute among themselves,

$$\begin{aligned} [(\vec{M} \odot \vec{M}) \cdot \vec{\Lambda}, \{ (\vec{M} \odot \vec{M}) \odot \vec{M} \} \cdot \vec{\Lambda}] &= 2i \left((\vec{M} \odot \vec{M}) \otimes \{ (\vec{M} \odot \vec{M}) \odot \vec{M} \} \right) \cdot \vec{\Lambda} \\ &= 0, \end{aligned} \quad (66)$$

Hence, in the process of ‘linearization,’ *three* commuting linear combinations of the $(N^2 - 1)$ matrices $\vec{\Lambda}$ arise naturally for $SU(4)$. They span the maximal abelian subalgebra associated with the element $\vec{M} \cdot \vec{\Lambda}$. Knowing (63) it is straightforward to (i) multiply two elements $\exp[-i\mathbf{M}]$ and $\exp[-i\mathbf{N}]$ of $SU(4)$, (ii) reduce the product to linear form by removing the single term quadratic in $\vec{\Lambda}$ in analogy to (46) and to (iii) reexponentiate using the prescription in (47).

9 Summary and Discussion

It has been shown how to explicitly calculate BCH-relations for the group $SU(N)$. The essential ingredients are (i) the property that products of generators $\Lambda_j \in SU(N)$ are expressible as linear combinations of generators, and (ii) the reduction of the spectral theorem to linearized form. It has been assumed throughout that the operators involved have no degenerate eigenvalues (this case could be included along the lines shown in [18], for example). The present approach is *not* restricted to exponential functions of operators which, however, seems to be the most important case in physics. Applications of these results are expected to deal with coherent states for the group $SU(N)$, useful for the description of lasers with N levels.

Both steps, (i) and (ii), are based on a surplus of structure in the algebra $su(N)$, i. e., the specific form of the anticommutator (11) which does not exist for all Lie algebras. Therefore, the generalization of this approach to other groups is possible whenever the *product* of two generators defines another element of the original algebra. In general, this is guaranteed only for the *Lie product*, the commutator. To put it differently, the Lie algebra must be closed under both commutation *and* anticommutation of its elements. Apart from $SU(N)$, this property also holds for the general linear group in N dimensions, $GL(N)$, for example.
