Policy Research Working Paper 5829

Abstract

This paper takes a bibliometric tour of the past 40 years of health economics using bibliographic "metadata" from EconLit supplemented by citation data from Google Scholar and the authors' topical classifications. The authors report the growth of health economics (33,000 publications since 1969—12,000 more than in the economics of education) and list the 300 most-cited publications broken down by topic. They report the changing topical and geographic focus of health

economics (the topics 'Determinants of health and illhealth' and 'Health statistics and econometrics' both show an upward trend, and the field has expanded appreciably into the developing world). They also compare authors, countries, institutions, and journals in terms of the volume of publications and their influence as measured through various citation-based indices (Grossman, the US, Harvard and the JHE emerge close to or at the top on a variety of measures).

This paper is a product of the Human Development and Public Services Team, Development Research Group. It is part of a larger effort by the World Bank to provide open access to its research and make a contribution to development policy discussions around the world. Policy Research Working Papers are also posted on the Web at http://econ.worldbank.org. The author may be contacted at awagstaff@worldbank.org.

The Policy Research Working Paper Series disseminates the findings of work in progress to encourage the exchange of ideas about development issues. An objective of the series is to get the findings out quickly, even if the presentations are less than fully polished. The papers carry the names of the authors and should be cited accordingly. The findings, interpretations, and conclusions expressed in this paper are entirely those of the authors. They do not necessarily represent the views of the International Bank for Reconstruction and Development/World Bank and its affiliated organizations, or those of the Executive Directors of the World Bank or the governments they represent.

Four Decades of Health Economics through a Bibliometric Lens

Keywords: Health economics; bibliometrics; history of economic thought.

JEL codes: B20; I10.

Acknowledgements: We are grateful to Martin Ravallion for helpful comments on an earlier version, and to Imran Hafiz for help in cleaning the data. The findings, interpretations and conclusions expressed in this paper are entirely those of the authors, and do not necessarily represent the views of the World Bank, its Executive Directors, or the governments of the countries they represent.

I. INTRODUCTION

According to Google's Books Ngram Viewer, the terms "health economics" and "Health Economics" started appearing in books only in the 1940s, four decades after the terms "agricultural economics" and "international economics" surfaced. The first two decades of health economics were slow, but in the mid-1960s use of the terms "health economics" and "Health Economics" increased sharply, and the growth has mostly continued since then.

In this paper, we take a bibliometric tour of the last forty years of health economics. Our bibliographic "metadata" are drawn from EconLit which dates from 1969 although it includes many earlier classic papers that were reprinted as chapters in collections published after 1969, including for example Arrow (1963). Unlike other databases such as the Social Science Citation Index, SCOPUS, and Medline, EconLit allows for a relatively clean definition of health economics based on EconLit's inclusion criterion ("a substantial economics content") and a publication's JEL codes. We run risks of omission and commission: there are many noneconomics and multi-disciplinary journals that have published many papers by health economists, and some authors may not have chosen a health JEL code despite their paper having a substantial health content; conversely, our net will catch some items that are devoid of economics (and not written by economists), as well as items where health is not the main focus of the publication. In any event, for reasons to be explained below, we had little choice. And our pragmatic definition of the sub-discipline enables us to avoid many esoteric considerations regarding, for example, the emphasis to be placed in characterizing health economics as the topics its practitioners study (e.g. financial aspects of health services) rather than the discipline (viz. economics) characteristically applied to understanding and explaining phenomena in health and health care (Culyer, 1981; Williams, 1979).

Our EconLit metadata include author, title, journal, the year of publication, author's institution, country of focus, keyword, and three-digit JEL code. EconLit does not include any citation data; for 78 percent of records in our dataset we were able to obtain citation data from Google Scholar. In addition to getting at influence through citations, we also want to say something about the topics that health economists work on. The JEL sub-categories are not

especially illuminating¹ and the keywords in the EconLit metadata are freely chosen by authors and unsurprisingly are highly heterogeneous. We therefore used our own topical classification system, and assigned a topic to a subset of our records manually. We aggregate our metadata to the author, institution and journal levels, showing which of each have published the most, and which of each have had the greatest impact in terms of citations. We show publication counts for both "country of origin" and "country studied". We present frequency distributions of the words used in titles and abstracts and keywords. We also show how the subtopic focus has changed over time and varies across the top institutions.

Two previous exercises are worth mentioning, although neither comes close in terms of comprehensiveness and ambition. Rubin and Chang (2003) undertook a bibliometric analysis of health economics articles over the period 1991-2000 using EconLit metadata. They also report author rankings (using number of articles and number of pages) but in most other respects their analysis is much more limited, covering a shorter time period, excluding citations, using the limited JEL topic classification system, and omitting many of the cuts of the data that we present. Also of note is the exercise Culyer undertook as background for his four-volume collection of 78 articles on health economics (Culyer, 2006). This was based on a survey of teaching members of the International Health Economics Association (iHEA) in 2004 that asked for their student reading lists, the objective being to ensure representation in the 2006 collection of those articles most frequently cited for student reference by people teaching the subject. His e-mail poll of iHEA yielded usable responses from 112 members and 164 articles that were included on at least two reading lists. We use this source as basis for making some intertemporal comparisons between health economics then (2004) and now (2011), and also for comparing the frequency of citations in general (in 2011) with literature recommended by specialist health economics teachers (in 2004).

The rest of the paper is organized as follows. Section II presents our methods, including the bibliometric methods used to analyze citations and the classification of health economics subtopics. Section III introduces our data. Section IV presents our findings, and section V our conclusions.

¹ They comprise: (a) Health: General, (b) Analysis of Health Care Markets, (c) Health Production, (d) Health: Government Policy; Regulation; Public Health, and (e) Health: Other. Recently two categories have been added: (f) Health and Inequality, and (g) Health and Economic Development.

II. COUNTING INFLUENCE THROUGH BIBLIOMETRICS

Publication counts capture the volume of output of an author, institution, journal or country. They do not necessarily capture the *influence* of that author, institution or journal on the research community. Citations are a commonly used measure of scholarly influence, the assumption being that a heavily cited paper is more influential than a less heavily cited paper, and that an individual who has authored several highly cited papers has been more influential among his or her peers than one who has authored a similar number of less cited papers.

The h-index (Hirsch, 2005), which we refer to below as I^1 , is the most widely used citation-based summary measure of scholarly influence, reflecting both the number of publications and the number of times they have been cited. An h-index of 20 means that an author (or institution or journal) has 20 publications to its name each of which has been cited at least 20 times. Figure 1 illustrates. It shows the citation curves for two publication portfolios (e.g. for two individuals). The horizontal axis plots the cumulative number of articles up to the total N, ranked in descending order of citations. The y-axis plots the number of times the nth article has been cited. The h-index is found by drawing a 45-degree line on the chart, and reading off the x-axis or the y-axis. Hirsch argues that this index is a robust and relevant measure of "...the importance, significance and broad impact of a scientist's cumulative research contributions" and the index is widely used. It is reported, for example, in citation software such as Publish or Perish (Harzing, 2010), SCOPUS and the Web of Science (which implemented the h-index within two years of the publication of Hirsch's paper).

The *h*-index has shortcomings. Both A and B in Figure 1 have the same *h*-index even though A's first few articles are cited far more often. In Figure 2 D has a higher *h*-index than C though C's citation curve might reasonably be argued to be the more impressive one on balance. Alternatives to the *h*-index have been proposed, but Ravallion and Wagstaff (2011) have argued they have unattractive properties. They proposed instead an axiomatic approach to measuring scholarly influence based on an influence function where influence is strictly increasing in the number of citations. If a publication portfolio has a citation curve that lies everywhere above that of another publication portfolio, the influence function approach will say the former has greater

² Alonso et al. (2009) provide a useful review of the literature on the h-index—a review that covers some 90 papers—in just four years since Hirsch (2005).

influence than the latter. Where citation curves intersect, Ravallion and Wagstaff impose the assumption of concavity—influence increases in citations but at a diminishing rate. This allows a second-order dominance test to be undertaken, but when a large number of portfolios are being compared this test becomes impractical.

Where citations curves intersect, Ravallion and Wagstaff suggest computing influence numerically. They propose a simple quadratic influence function (QIF)³:

$$(1) I^2 = \sum_i \left[2 - \frac{c_i}{c_{MAX}} \right] \frac{c_i}{c_{MAX}},$$

where c_i is the number of citations to the *i*th publication and c_{MAX} is the maximum number of citations encountered in the dataset. An increase in c_i increases I^2 but does so at a diminishing rate: I^2 is concave in c_i . The maximum value of the term in I^2 for each publication is 1. The maximum aggregate influence is obtained when the portfolio containing the most-cited publication is the largest of all portfolios, and all publications in the portfolio have been cited c^{\max} times. This approach gives A more aggregate influence than B in Figure 1 even though A and B have the same h-index. It also gives C more influence than D in Figure 2 even though D has the higher h-index.

Unfortunately, however, the QIF approach can also lead to rankings that might be questioned. It focuses completely on citations and rewards additional publications only insofar as they generate additional citations. Even with concavity in the influence function, one can end up with an author who has published only one (albeit highly cited) article (and therefore has an *h*-index of 1) coming out ahead of another who has published multiple quite highly cited articles (perhaps with an *h*-index in the tens). In fact this happens a lot in our dataset; indeed, it turns out that the QIF is almost perfectly (rank) correlated with total citations in most cuts of our data. As a supplement to the QIF—but in keeping with the idea of diminishing marginal influence—we use an index inspired by Foster et al.'s (1984) poverty index: there the goal of the index is to reflect not just the aggregate shortfall from the poverty line but also the number of people in poverty; here our goal is to capture not just the number of citations but also the number of articles that have been cited. Our third index is thus:

-

³ They also suggest a variant on it, but it does not resolve the problem we highlight below.

$$(2) I^3 = \sum_i c_i^{\alpha},$$

where $\alpha \ge 0$ is a coefficient. The closer α is to 0, the closer I^3 comes to capturing just the number of publications. (In this case, we have to add an arbitrarily small amount to c_i in order for uncited papers to count toward the publication count.) The closer α is to 1, the closer I^3 comes to capturing the total number of citations. With $0 < \alpha < 1$, I^3 is concave in c_i . With intermediate values of α , I^3 captures the idea that citations are associated with diminishing returns in producing scholarly influence but that additional citations always add something to influence (something that does not occur with the h-index). But we are also able to capture the idea that the number of publications of itself matters (something that *does* happen with the h-index).

All three measures we have considered thus far speak to the *total* influence of a publication portfolio. Particularly in the case of journals—but also perhaps with institutions and individual researchers—one might reasonably want to get a sense of *average* influence. After all, there is often large variation between journals in the number of articles they publish per year, and in the number of years they have been publishing. Ravallion and Wagstaff (2011) introduced the *normalized h-index*: a value of 20 means that 20% of articles have received at least 20 citations. This measure adjusts for the scale of the publication portfolio. We report this for journals as well as for edited volumes.

III. DATA

In this section we introduce our data, explaining our choice of database, how "health economics" was defined, how we cleaned the "metadata", and how we supplemented our metadata with citation and topic data.

Database choice

A number of online bibliographic databases include articles (and in some cases other types of publication) on what could be construed as "health economics". These include EconLit⁵,

⁴ This should not be confused with the h-index per publication, which is also called the "normalized h-index" in some of the literature (Alonso et al., 2009).

⁵ Details of EconLit coverage are to be found at http://www.aeaweb.org/econlit/doctypes.php.

MedLine, the Social Science Citation Index⁶ (SSCI), and SCOPUS⁷. These vary along key dimensions, one fundamental one being whether the database employs a classification system that allows us to make a credible distinction between "health economics" publications and others. Many databases do not pass this test for any plausible definition of "health economics". MedLine, for example, includes hundreds if not thousands of articles that would be classified as "economics" using the MeSH major topic. But many—if not most—have no economic analysis in them to speak of, and are written by people who quite probably would never claim to be an economist. SCOPUS and the SSCI are the other extreme. In SCOPUS, articles are classified as either "economics, econometrics and finance" or "health sciences" (but not both). SSCI does permit cross-classifications but trying to pin down "health economics" results in a very narrow set of articles. Limiting publications to those that are classified as (a) "economics" and (b) either "health policy and services" or "health care sciences and services" results in just 2,201 publications, all of which are in just six journals: Value in Health, Health Economics, PharmacoEconomics, the Journal of Health Economics (JHE), the European Journal of Health Economics, and the International Journal of Health Care Finance and Economics. This would be a very narrow definition of "health economics" indeed. MedLine, SSCI and SCOPUS also all cover a limited range of publications. All three focus largely on journals, and MedLine focuses on medical journals and thus omits the core of the "health economics" literature.

Because MedLine, SSCI and SCOPUS all lack a classification system that enabled us to separate out "health economics" from other fields, and because they all have a limited coverage of publications, we decided to look instead to EconLit as the source of our bibliographic metadata on health economics publications—the same data source used by Rubin and Chang (2003). Its two big advantages are its scope and its JEL classification scheme. The number of titles has increased steadily since 1969 when the database started. EconLit now includes over 750 journals "with substantial economics content". It has also included books, book chapters and doctoral dissertations since 1987, and for several years has also included working papers through

⁶ SSCI covers primarily journal articles and is limited to about 2,500 social science journals. Details of coverage are to be found at http://thomsonreuters.com/products services/science/science products/a-z/social sciences citation index.

⁷ SCOPUS covers over 18,000 titles covering all disciplines including 16,500 peer-reviewed journals, as well as some book chapters, including the North-Holland handbook series. Details of the database are to be found at http://info.scopus.com/scopus-in-detail/facts/.

⁸ Alternatively we could have ignored the database's classification system and tried to classify publications on the basis of the words in titles, abstracts, and keyword lists. This would have been very laborious and would likely have caused us to end up with lots of errors of omission and commission.

the REPEC project. The JEL classification scheme used by EconLit changed in 1991 but both the old and the new schemes have codes for health⁹; like Rubin and Chang (2003) we define "health economics" publications as those appearing in EconLit with one of the health JEL codes.

With EconLit and the health JEL codes we feel confident we are getting a very large share of the corpus of "health economics" understood to be publications that involve the discipline of economics being applied to the topic health. We acknowledge, however, that our 33,000 publications may exclude some that should be in our database, and may include some that perhaps ought not to be in it. On omissions, we miss the genuine health economics articles in non-economics journals not included in EconLit. We also miss health economics publications in EconLit when the author did not choose a health JEL code even if his or her publication contains a substantial amount of material on health. ¹⁰ For reasons explained earlier we cannot do anything about the former, and of course we cannot do anything about the latter if we rely on JEL codes. On commissions, we will end up including some publications where, despite EconLit's inclusion criterion, the publication contains little if any economics. And we will end up including some publications where, despite the article having a health JEL code, the publication's health content is small or negligible: health could be just one of several issues addressed in the article (articles are permitted multiple codes, and many span health and other topics)¹¹, or health might be the chosen application for a paper outlining a new econometric method¹². In most of our analysis we retain all records and do not attempt to identify clear or marginal false positives. We accept that there will be publications where the inclusion could be debated, but hope that with 33,000 records any variation in classification practices will get washed out when ranking institutions, individuals, countries, etc. However, in our analysis of topics, we have dropped publications that manifestly have zero economic content despite EconLit's inclusion criterion and/or zero health content despite the JEL code. We have, however, retained in the topical analysis publications with only a small amount of health content; we flag in the text such publications.

⁹ See http://www.aeaweb.org/econlit/search_hints.php.

¹⁰ An example of this is Anand and Ravallion (1993) which does not have a health JEL code despite the word "health" occurring 58 times in the article.

¹¹ Deaton (2006) is an example of this.

¹² Angrist et al. (1996) is an example of this.

Authorship

On multi-author papers, we give each author equal credit for the paper insofar as EconLit allows us to. This is in contrast to Rubin and Chang (2003) who gave authors of papers with two authors only half a paper's credit each, and authors of papers with three authors only one third a paper's credit. Unfortunately, EconLit lists only the first author when the original list includes more than three or four authors. ¹³ In such cases, authors other than the first get no credit in our study as in Rubin and Chang's; the EconLit user has no alternative in such cases.

The author data required a good deal of cleaning. Many authors appear in different forms, sometimes with different spellings. The top 250 authors in terms of publication counts were all checked manually for multiple spellings and forms, and the scattered records aggregated; the same manual cleaning was applied to other authors who ranked highly on one or more of the indicators. The trickiest person proved to be Matthias von der Schulenburg, whose name appeared in no less than ten different forms. ¹⁴ The funniest was Adam Wagstaff, who after years of writing with Eddy van Doorslaer became "Adam van Wagstaff" in one paper.

Affiliation

The EconLit author-address field gives the author's address (affiliation) at the time of publication of the article (actually at the time of proof-correction). The field is empty until the early 1980s, so the results below are for the period 1981-2010. The information in the author-address field needed some manual cleaning, and some explanation of what was done is in order. Some clarification is also in order on the issue of joint authorship.

Each unit record (one per publication) generated multiple author-address records depending on the number of authors and whether or not they shared an affiliation. The maximum number of lines in the author-address field is equal to the number of authors listed. If a publication has, say, two authors working at two different institutions, we count the publication twice—both institutions get full credit for it. If the two authors share the same address, the

Rubin and Chang (2003) report this happens when the list exceeds three, but several recent EconLit records have four authors.
He For those anxious to dig up Prof von der Schulenburg's work, here are the ten permutations: J. M. Graf von der Schulenburg, J. Matthias von der Schulenburg, J. Matthias Graf von der Schulenburg, J. Matthias Graf von Schulenburg, J. Matthias Graf v. d. Schulenburg, J. Matthias Graf von der Schulenburg, and J. M. Graf v. d. Schulenburg. Prof von der Schulenburg's records were cleaned because he was in the top 250 on the basis of publication count.

shared address appears only once in the EconLit record, and we count the article only once for that institution. Where an author has multiple affiliations, these appear on the same line in the EconLit record, we retained only the first-listed address—the first-listed institution gets all the credit. Adopting these rules, we inevitably end up with more records than publications: we have over 37,000 "publications" just for the sub-period 1981-2010.

We then aggregated these "publications" by address, and then by institution. Sometimes, an author's address was the institution itself, and the aggregation involved simply checking for variations in spelling or format and deciding on a common one. So, for example, the US Department of Agriculture sometimes appeared as "USDA" and sometimes as "US Department of Agriculture"; we renamed the former "US Department of Agriculture" and the two sets of records were aggregated. Other examples include the World Health Organization (which appeared also as WHO) and the International Food Policy Research Institute (which also appeared as IFRPI). Sometimes, the author address was not an institution but rather a unit within an institution. For example, authors affiliated to the University of York's Centre for Health Economics (CHE) often listed their address as CHE not the University of York. Other authors at York listed their address as the Department of Economics and Related Studies. Often these and other addresses appeared in multiple forms, with, for example, abbreviations. In such cases, we aggregated records up to the institution level—the University of York in the example above. The same rule was applied to records relating to the colleges of the universities of Cambridge and Oxford, but was not applied to constituent colleges of state universities in the US or the universities of London and Wales. 15 So, Berkeley stayed as University of California Berkeley, and the London School of Economics and the London School of Hygiene and Tropical Medicine (both part of the University of London) stayed as distinct institutions.

We identified 13,500 distinct author addresses in our dataset. We quickly realized that the cleaning and aggregation process would require a lot of manual input by someone familiar with the names and common abbreviations thereof of academic institutions and think tanks. To turn this into a manageable exercise, we required that an address had to occur at least five times for it to be retained for cleaning and aggregation. So, for example, the inappropriately Americanized

¹⁵ Some authors listed their affiliation simply as the University of London; in such cases, there was obviously no choice but to leave the affiliation at the university rather than college level.

"Center for Health Care Econ, U York" (1 publication) was not retained for cleaning and aggregation, while the appropriately Anglicized "Centre for Health Econ, U York" (81 publications) was. Imposing this rule resulted in us dropping 12,500 of our 13,500 author addresses. This would be a calamity were it not for the fact that publications are highly unequally distributed across author addresses. The 980 records we retained accounted for around 21,500 (60 percent) of our 37,000 "publications". We think it unlikely that our "rule of five" will have had much—if any—effect on the ranking of institutions, at least at the top of the distribution: it seems likely that (say) Harvard and Yale will be just as likely to have lots of odd spellings for their various departments and research institutes; and in any case, almost 85 percent of the dropped author address records had only one publication to their name.

Citation data

Like Medline, and in contrast to SSCI and SCOPUS, EconLit has no citation data. For the purpose of this study, therefore, each publication was looked up in Google Scholar¹⁶ and the number of citations recorded (the numbers in the paper reflect citations as of June/July 2011). Google Scholar has some attractions over SSCI and SCOPUS as a source of citation data. It captures a very broad set of publications, including books, book chapters, established journals, new journals, open-access journals, technical reports, and even dissertations. This means that we end up finding citation data for a large fraction (85%) of our EconLit records. It also means that the citation data capture scholarly influence across a wide range of publication types, not just a narrow range of academic journals.

As a source of citation data, Google Scholar does, however, have its disadvantages. Titles are also sometimes incorrect, incomplete, ambiguous, or appear in multiple versions. The tool we used to "harvest" citation data went through multiple versions before we could be sure it could cope with mispunctuation and misspellings. Even then we found mistakes, and had to correct manually or drop records that were flagged as outliers and/or which erroneously appeared highly ranked in the tables below. One defect of Google Scholar we have not corrected is the scattering of citations across multiple documents. Some publications appear with somewhat different titles in draft form or in working paper form, and will appear as different publications in Google

¹⁶ For details of Google Scholar coverage, see http://scholar.google.com/intl/en/scholar/inclusion.html.

Scholar. Modifying the harvesting tool to aggregate across these variants would be very hard, because one needs to know which records are indeed variants of a single publication and which are simply similarly named publications.

Finally, we should note that our citation data are discipline-blind. We do not—and could not—impose the requirement that the citing author be an economist. Doing so would necessitate working manually through each document citing each of the 33,000 records in or database and establishing the discipline of the citing author. In any case, it is not clear whether such an exercise make sense; we are, after all, interested in the overall impact of each item in our database. We should also point out that we do not eliminate self-citations. Doing so would necessitate another manual check all documents citing each of our 33,000 publications. This would have the advantage of eliminating gratuitous self-citation. But insofar as an author is citing his or her previous work in taking the idea forward in a new publication, a self-citation is no different from a citation by anyone else. So even if it were feasible to eliminate self-citations in our citation data, it is not clear we would want to.

Topic classification

Beyond influence measured through citations we are also interested in the topics covered by the more influential of our 33,000 publications, and how the topic mix has varied over time and varies across the more influential institutions.

The JEL system used by EconLit does have subcodes, but as the article by Rubin and Chang (2003) makes clear, it is not a very informative one. Alternative classifications exist that we could have used to apply a topic code to the EconLit records. The first was developed by Cooper and Culyer (1973). At that time, the subject was relatively undeveloped and the literature sparse. They used four categories: "economic efficiency", "improving decisions", "hospitals", and "the value of human lives", revealing a British set of interests (though the literature selected for inclusion was not merely British). Much later Williams (1987) developed a "plumbing" diagram for categorizing and linking topics within health economics. This still betrayed a British focus (for example 'medical insurance' found little space in it) and Culyer enlarged and modified it in a number of ways in his four volume collection of reprinted papers (Culyer, 2006). Jones' (2006) classification scheme for "The Elgar Companion to Health

Economics" is yet another recent and reasonably comprehensive set of topics. The JHE uses yet another classification system, grouping articles into: production of health and health services; demand and utilization of health services; financing of health services; measurement of health; behavioral models of demanders, suppliers and other health care agencies; manpower planning and forecasting; the prevention of sickness; cost-benefit and cost-effectiveness analyses and issues of budgeting; and efficiency and distributional aspects of health policy.

In the event, we opted for the following 12 topic groups: (1) health and its value; (2) efficiency and equity; (3) determinants of health and ill-health; (4) public health; (5) health and the economy; (6) health statistics and econometrics; (7) demand for health and health care; (8) medical insurance; (9) supply of health services; (10) human resources; (11) markets in health care; and (12) economic evaluation. The classification scheme is explained more fully in the Appendix.

The assignment of topics to publications was done manually. To ensure consistency, process was completed by just one of us (Culyer). Many articles could be assigned readily on the basis of their titles but in more than half of cases the abstract was also used. In about one quarter of cases, the full pdf was downloaded in Google Scholar before the final assignment was made. Assigning a topic to all 32,000 publications was clearly infeasible. Instead, we assigned topics to all publications in each of the following groups: the most-cited 300 publications; the most-cited 50 publications in each of the four decades studied; the most-cited 50 publications by each of the following institutions: Harvard, Berkeley, MIT, Chicago, the World Bank, and the University of York; the most-cited 50 publications from each of the United States, the United Kingdom, Canada and the Netherlands. In total, a topic was assigned to 694 publications.

The allocation is a little arbitrary at times: some articles span multiple categories, as when, for example, they are methodologically innovative (which might get them into category (6) but also have a specific application, which will typically place them elsewhere. Three categories—(7), (10) and (11)—are somewhat prejudiced by being elements in a very large number of papers in all topic areas, whereas we have included in these three groups only papers whose particular focus appeared to be on one of these three.

Just under 11 percent (74) of the 694 publications allocated for topic assignment were not in the event assigned to a topical group. The most-cited items amongst these were textbooks (led by Paul Feldstein) which, by definition, paint on a much broader canvas. Others included the quite extensive reference made by economists to the literatures of demography and epidemiology written by scholars of those disciplines. The most frequently cited excluded source that was not a textbook was Scott and Meyer's book on organization theory and application "Institutional environments and organizations: Structural complexity and individualism": a pioneering and hugely influential sociological work whose impact on economists is indicated by its being the 63rd most cited source.

Some titles were found to be superficially misleading. For example, Kremer's excellent "The Illusion of Sustainability" (Kremer and Miguel, 2007) may appear superficially to belong to category 5 (Health and the economy) but is in fact about the evaluation of public health options in Kenya (category 12, Economic evaluation). Some authors excel at the invention of intriguing but slightly baffling titles. Mark Kamstra's "Losing Sleep at the Market: The Daylight Saving Anomaly" (Kamstra et al., 2000) turned out to about equity returns in international capital markets in consequence of sleep disruption, and so was excluded. Contoyannis et al. on "The Dynamics of Health in the British Household Panel Survey" (Contoyannis et al., 2004) could on the face of it have been assigned either to category 1 (Health and its value) or 3 (Determinants of health and ill-health) but on closer inspection was assigned to category 3 given its concentration on the impact of health status in a previous period on the probability distribution of current health status, and on the impact of socio-economic determinants. Articles that were about both supply and demand were assigned according where the balance of emphasis seemed to lie or, where the balance was even, to category 11 (Markets in health care). Siciliani and Hurst's (2004) "Explaining Waiting-Time Variations for Elective Surgery across OECD Countries" was thus assigned to category 11.

IV. RESULTS

Figure 3 shows the cumulative growth of health economics publications in EconLit since 1969. Also shown is the cumulative growth of publications in the economics of education. The two fields ran neck and neck up the early 1980s, whereupon health economics started to grow

much faster. As noted by Blaug (1998), the two sub-fields took different routes with health economics inspired by Arrow's work on medical insurance, interest in the way that health institutions operated (especially the non-profit sector), in the economic aspects of wider political controversies about health care financing, in the measurement of the outputs of health care systems, in addressing issues of 'equity' almost as much as those of 'efficiency' and, especially of late, in the application of cost-effectiveness methods in the multi-disciplinary field of what has become known as "Health Technology Assessment". By the end of our period (2010) health economics had notched up over 33,000 publications, 12,000 more than education economics.

Articles and topics

Table 1 lists the 300 most-cited publications in health economics for the full period, organized by topic and excluding publications, such as textbooks, that traversed the whole field. The largest category ('Determinants of health' – 16%) includes several classic articles such as Becker et al. (Becker et al., 1994), the fourth most cited article in health economics as a whole. It also includes a classic book by the Frank Ramsey Professor at Cambridge (Dasgupta, 1993), followed at some distance by Fogel (1994) again on a 'big' theme. Other heavily cited classics include Smith (1999) on the health-wealth nexus, Mosley and Chen (1984) on childhood survival in poor countries, Pritchett and Summers (1996) again on the health-wealth nexus, Chaloupka and Warner (2000) on smoking and health, and Deaton (2003) on inequality and economic development. This category also includes several papers looking at behavioral determinants of health, the economics of 'bad' habits in addition to the addictions, the role of education in shaping lifetime health, other determinants of lifetime health such as early parenting and childhood nutrition.

The second largest category is 'Economic evaluation' (11%) led by three classics each having more than 1,000 citations: Torrance (1986) on standard gambles and health measurement, Weinstein (1991) on the key ideas of cost-effectiveness analysis, and Tengs' (2004) review of 500 life-saving interventions. Very close in size are 'Public health' and 'Health and the

¹⁷ According to Google Books Ngram Viewer, HTA took off spectacularly in 1980.

¹⁸ The percentages are defined in terms of the 260 articles among the top 300 that were assigned a topic. Not all of the top-300 were assigned a topic. Some, for example, were considered too general and some were not considered part of the health economics corpus despite their JEL code and inclusion in EconLit.

economy'. None of the most cited items in 'Public health' exceeds 1,000 citations but it is led by two classic applied papers: Becker, Grossman and Murphy (1994) on cigarette addiction (placed here rather than 'Determinants' on account of its emphasis on smoking reduction), and Cutler, Glaeser and Shapiro (2003) on American obesity. This category also includes economic analyses of risk factors, heat waves, AIDS and violence. 'Health and the economy' is led by Rodrik (2004) on economic development and DiMasi et al. (2003) on pharmaceutical innovation. The other papers explore further the two-way links between health (or health care) and the wider economy: growth, the economic cycle, unemployment, and private and public expenditure.

'Supply of health services' has a historically characteristic focus on hospitals as non-profit institutions, managed health care organizations and the ways in which such institutions respond to changes in their financial environments. None of the items in this category reach the rates of citation of the most cited papers. The most cited paper in this group (Cleary and McNeil, 1988) was 32nd in the overall ranking, the next most highly cited paper was 40th (Scott and et al., 2000). Newhouse's (1970) pioneering paper and Pauly's (1973) classic are two of the earliest papers referenced in health economics. Most of the papers in this group originate from the US and reflect US institutional concerns. 'Medical insurance' is long-standing health economics territory and the first four items in the group were each cited more than 1000 times. These include Arrow (1963) (cf. Arrow, 2001, reprinted on several other occasions too), which many consider the founding paper of the sub-discipline, Manning et al. (1987) reporting of the RAND Health Insurance Experiment, Pauly's (1968; 1991) comment on Arrow (though not Arrow's reply!), and Barsky et al. (1997) with their famous paper on risk tolerance, time preference, and intertemporal substitution.

'Efficiency and equity' as a group has relatively few US contributions and, given the dominance of US economists in the field, this may also explain why the citation rates are not higher. The group includes both methodological contributions and applied studies, including international comparisons, and covers equity in both the financing and delivery of health services. 'Health statistics and econometrics' contains six contributions with citation rates above 1,000 and relatively few published before 2000. Some of these publications (e.g. Angrist et al., 1996) simply have health as an application and the usefulness of the paper extends well beyond the health field. In other cases (e.g. Duan and et al., 1983) the paper sets out to address an

econometric or statistical issue that crops up only in or disproportionately in the health field. Like 'Economic evaluation' 'Health statistics and econometrics' is a relatively mature development within health economics. 'Health and its value', although not a major focus of work for most health economists, contains the most cited article of all (Acemoglu et al., 2001) as well as many articles relating to the concept of health, its measurement and its valuation. (Valuation questions specifically in the context of economic appraisals were placed in 'Economic evaluation'.) 'Human resources' focuses mainly on physicians and their professional behavior patterns. 'Demand for health care', despite its centrality for economists, was a relatively small group but dominated by the extremely heavily cited classic by Grossman (1972). 'Markets in health care' is the smallest group – perhaps surprisingly. There is, of course, a sense in which the idea of markets, exchange and the interaction of demand and supply underlie nearly all health economics and this may help to explain the puzzle. Beyond Shleifer's (1985) classic, which far transcends health, most of the items in this group were much less frequently cited than those in the other groups.

Table 3 shows the topical breakdown of the 50 most-cited publications in each decade. (The numbers do not add to 50 necessarily because some publications were not allocated to a topic.) Some exhibit no clear trend: the 1990s saw classic papers appear in the areas of 'Health and its value' and 'Economic evaluation'. By contrast, the topics 'Medical insurance' and 'Supply of health services' show a clear downward trend, while the topics 'Determinants of health and ill-health' and 'Health statistics and econometrics' show a clear upward trend. These diverging trends may also reflect of course the prior discovery effect: the early years saw a large volume of publications on insurance and supply issues, and the big breakthroughs had already occurred by the end of the 1980s. But it seems likely that the changes also reflect a broadening of interest in health economics.

The impression of a broadening scope of the sub-discipline is indicated in Figures 4 and 5, which are based on the commonest 150 words in the titles of all articles, not just the most cited ones. Judging from the title words, the topical focus of health economics articles has indeed broadened over the four decades, away from hospitals, insurance and the demand for health and health care, to a more diverse set of topics, with a greater degree of attention to specific

applications, substantial technical developments in econometrics, and more interest being shown in the health economics of low-income countries.

Countries studied

Our bibliographic metadata include the country or countries studied by each paper. Figure 6 shows the frequency distribution of countries studied for the full period 1969-2009. The dominance of the US is striking. What Figure 6 conceals is the broadening that has occurred over the last 40 years in the countries studied by health economists, revealed by the maps in Figures 7 and 8. The second map, which has the same cut-off points as the first, is distinctly darker in all continents; the darkening is more pronounced, however, in Africa, Asia (especially China and South East Asia), Europe, and South America than in Australasia and North America. Despite the broadening of geographic focus during the last two decades, however, central Asia, Africa, and the Middle East remain relatively under-researched by health economists.

Authors

Our data contain 1,876 economists with 5 or more health economics publications in EconLit over the period 1969-2010. Twenty-eight percent of these have produced 10 or more publications. To get a sense of how the different bibliometric measures rank the authors of health economics publications we report in Table 4 the rank correlations across (a) the publication count (equal to the I^3 index with α =0), (b) total citations (equal to the I^3 index with α =1), (c) the h-index (referred to above as I^2), (d) the QIF index (referred to above as I^2), (e) the I^3 index with α =0.5, and (f) the citations of the author's most-cited publication. Note that the citations of the most-cited paper is highly (rank) correlated with total citations and the QIF index; unsurprisingly, its (rank) correlation with the count is very low, and its (rank) correlation with the h-index is also a good deal lower than with most of the other indicators. Authors like Acemoglu, Arrow and Becker, who have published classic papers in the field, have not necessarily published a lot of other highly cited papers in health economics: Arrow's (1963) paper, for example, is the second most cited paper in health economics (Table 1) but Arrow is not among the top 100 health economists on the h-index (table 5). Conversely, authors like Cutler who have published a large number of quite highly cited papers have not necessarily

published any of the most cited papers in the field: Cutler has the highest h-index (Table 5) but his most cited paper is only the 42nd most cited paper in the field (Table 1) and he ranks only 78th in the author ranking in terms of the maximum citations (Table 5). 19 Note also that the OIF index is perfectly (rank) correlated with total citations; thus in practice the QIF index simply tracks total citations. Note finally that the I^3 index with α =0.5 is also highly—though not perfectly— (rank) correlated with total citations, but is more correlated with the h-index and with total publications than the QIF index is. Thus whilst the I^3 index with α =0.5 also rewards citations, it penalizes authors whose citations come from one or two papers—albeit less so than the h-index. So, for example, Grossman comes top on total citations and on the QIF index, 6th on the h-index, but 4^{th} on the I^3 index with $\alpha = 0.5$ (Table 5).

Table 5 shows the world's top-100 health economists in terms of the h-index. 20 Also shown are the other indices, the fraction of publications not found in Google Scholar, and the citations of the author's most-cited publication. We have not imposed a minimum number of publications to be considered a health economist; in the event the top 100 all have at least 15 health economics publications to their name. Cutler emerges top on the h-index and on the I^3 index with α =0.5, Pauly comes out top on publications, and Grossman comes top on total citations. 21 Five authors come in the top 10 on total publications, total citations, the h-index and I^3 with α =0.5, namely Cutler, Gruber, Newhouse, Pauly and Viscusi. Five more emerge in the top 20 on all four measures, namely Currie, Grossman, Sloan, Wagstaff and van Doorslaer. The rest of the top-20 are not in the top-20 on all four measures, but are all in the top-100 on all four measures, and most are also in the top 50 on all four measures. Among the 80 authors ranked 21-100 on the h-index, only 25 are in the top-100 on all four indices. The list includes several elder statesmen (and one woman) of health economics: Alderman, Deaton, (Martin) Feldstein, Manning, Fuchs, Wolfe, and Williams (deceased).

Seventy one of the top-100 health economists are Americans. The rest include 17 Britons (at least one of whom—Haddad—has dual nationality), four Swedes, three Dutch, a Belgian, an Indian, a Swiss, and a Zimbabwean; many of the non-Americans work—or have worked for

¹⁹ The two ranks differ because of coauthors.

There were multiple ties around the 100 cutoff point, so we list here the top 95. Including the next tied batch would have taken us well over 100. 21 Grossman also comes top on and on the QIF index, I^2 , hardly surprising given how closely it tracks total citations.

large parts of their careers—in the US. Most (85) of the top-100 are also men. The US dominance is a little less pronounced in the top-50 (only 62 percent are Americans), but the male dominance is equally pronounced in the top-50 (88 percent of the top-50 are men).

Institutions

Our dataset contains 738 institutions with five or more health economics publications in EconLit. (Recall the author's affiliation is at the time the publication was published.) Over half of these (420) have ten or more, and 30 percent have 20 or more.

Table 6 shows the top 100 institutions in terms of the h-index. These 100 institutions account for 62% of health economics publications since the start of the 1980s when author affiliation data started to appear in EconLit records. Also shown in Table 6 are the other indices, the fraction of publications not found in Google Scholar, and the citations of the institution's most-cited publication. Harvard emerges the clear winner, beating others on the h-index, the publication count, total citations and the f^3 index with α =0.5. Seven institutions come in the top 10 on total publications, total citations, the h-index and f^3 with α =0.5, namely Harvard, the World Bank, UC Berkeley, U Chicago, U PA, U MI, and U York. Among the top-10, only MIT is not in the top-20 on all four measures. Eight of those ranked 11-20 are in the top-20 on all four measures, the exceptions being Cornell U, Princeton U and PA State U. Among the 80 institutions ranked 21-100 on the h-index, 61 are in the top-100 on all four indices. Most of the 39 not in the top-100 on all four measures appear in the lower part of the top-100 on the h-index. It is noteworthy that many of the top-100 institutions are not universities.

Table 7 shows the 10 most cited publications of each of the top-10 institutions (based on the *h*-index, as listed in Table 6). The table suggests some differences in topical specialization across the institutions. This is borne out by Table 8 which shows the distribution by topic of the most-cited 50 publications of the top-5 US institutions and Europe's top institution. The (normalized) Herfindahl index shows (in this instance) the degree of concentration of an institution's publications on a small number of topics. A value of 0.33 would occur if an institution's top-50 publications were evenly split across just three topics. Harvard U is the least specialized—appreciably less specialized than MIT (which has a high degree of specialization in

'Medical insurance') and U CA Berkeley and Chicago U, both of which show a fairly high degree of specialization in 'Determinants of health and ill-health'. Harvard U is dramatically less specialized than U York, which specializes heavily in 'Economic evaluation' and to a lesser extent 'Health and its value' and 'Efficiency and equity', and the World Bank, which is fairly specialized in 'Determinants of health and ill-health' and to a lesser extent 'Health and the economy'.

Countries of origin

Unsurprisingly in view of Table 6, the US dominates health economics. As table 9 shows, the US comes top by a substantial margin on total publications, total citations, the h-index, and the I^3 index with α =0.5. (We base the country of origin on the author's affiliation at the time of publication of each publication.) The UK comes second on all four indices, but the UK's h-index is just half that of the US's. Canada comes third on all four measures; it is some way behind the UK and only marginally ahead of Australia, the Netherlands and Sweden whose rankings vary across the four indices and who all come fourth or fifth on at least one index. The US, of course, may do less well on a population-adjusted basis, but it is not obvious whether such an adjustment makes sense. Arguably the US *ought* to be doing more research than other countries since its health system is so different from those of other countries—there may be thus less complementarity of research between the US and the OECD countries than there is among the other OECD countries.

Unsurprisingly, few non-OECD countries make it into the top-25. Taiwan (China) is the highest-ranking non-OECD territory, the next being China and S Africa. Table 10 shows the top 25 institutions on the h-index from non-OECD countries. U Cape Town comes out top on publications, but the National Taiwan U comes out top on total citations, the h-index and the I^3 index with α =0.5. Taiwan (China) and S Africa both have four institutions in the top-25, while China and India both have three, two of China's being in Hong Kong SAR, China.

Table 11 shows the topical distribution of the top four countries' top-50 publications, along with the (normalized) Herfindahl index computed as in Table 8. The United Kingdom is the most specialized country, focusing heavily on the topic 'Economic evaluation'. The

Netherlands is somewhat less specialized (covering 'Efficiency and equity' and 'Economic evaluation'), but is still more specialized than Canada and the United States. Interestingly, the topics of the most-cited papers in the US are not on topics such as 'Medical insurance' and 'markets in health care', but rather the topics 'Determinants of health and ill-health', 'Health and the economy', and 'Health statistics and econometrics'.

Journals and edited volumes

Table 12 shows the top-100 journals in health economics on the basis of their h-index for health economics articles only. Also shown are number of articles, total citations of these articles in Google scholar, the I^3 index with α =0.5, and the normalized h-index. The JHE dominates Health Economics on both the h-index and the normalized h-index, which in turn dominates PharmacoEconomics and the other specialized health economics journals on both criteria. The JHE fares worse than many journals on the normalized h-index: over 60% of health economics articles in Econometrica have been cited 60 times or more, as is the case for health economics articles in the J Political Economy, the Quarterly J of Economics and the J Economic Literature; several other general journals also fare better than the JHE on the normalized h-index though less spectacularly than these top journals. These are all general journals, of course; their editors have the freedom to change the fraction of articles they publish on health economics according to the quality of submissions—an option that is not open to the editors of JHE and other specialized health economics journals.

Table 13 shows the top-25 edited volumes in health economics based on the h-index. The Handbook of Health Economics dominates the others by quite a wide margin on both the h-index and the normalized h-index; at 76 percent, the Handbook's normalized h-index is better than any journal, suggesting a remarkably adept choice of chapters and authors by the editors as well as a consistently high quality of papers. Two other collections also fare well on both the h-index and the normalized h-index, namely "The economics of health" and "Health sector reform in developing countries: Making health development sustainable".

V. CONCLUSIONS

We have focused on the past 40 years. Health economics did, of course, exist before 1971 as we have already noted. Here we reflect on what went on before our starting date and offer some comments on the state of the subject. In his Foreword to Uncertain times: Kenneth Arrow and the changing economics of health care (Hammer, 2003), the 40th birthday Festschrift celebrating Ken Arrow's 1963 classic, Mark Pauly nicely observed that this article "made research in health economics respectable. But it did more than that. It made it interesting." He went on to identify two attributes of the article that laid the foundations for health economics: "It showed how some behaviors in medical markets could be brought within the purview of standard economic models of competing, maximizing agents ... (and) offered an explanation that atypical institutional arrangements in medical care markets are a reaction to special features of this market. ... In doing so, it discussed concepts that made (and make) economists attentive but uncomfortable, like trust and morals" (pp. vii-viii).

Prior to "Uncertainty" and, indeed, for some while after its appearance, the literature of health economics was exceedingly thin and more descriptive than analytical. The first textbook in health economics (Klarman, 1965) was in part a plea for more attention from economists: "Few economists work actively on the problems of the health field" (p.10). The bibliography in this book has remarkably few items, by today's standard, by health economists – nor, indeed, by economists of any hue. Much the same was true in 1972, when Victor Fuchs published his celebrated Who shall live? (Fuchs, 1972) whose bibliographies still contain few contributions by economists. Much was made of listing the characteristics of health and health care that seemed to mark it out from other goods and services, often with the implication that the mere recitation of (qualitative) characteristics provided sufficient grounds for public intervention. An early pioneer in this vein was Selma Mushkin (1958) who also, however, laid some of the foundations for health as investment (Mushkin, 1962). Those few economists who did take an interest would scarcely have described themselves as 'health economists', typically having much broader research interests: economists like James Buchanan in the US (Buchanan, 1965) and the Jewkeses in the UK (Jewkes and Jewkes, 1961) who gave some ad hoc (and usually critical) attention to the UK's National Health Service. A notable exception was Burton Weisbrod, whose article on human capital (Weisbrod, 1961) was an analytical precursor of Grossman (1972)

though not in fact cited by him (Mushkin (1962) was, however, cited). In the early 1960s, as now, the US was dominant. In the UK only two economists spent a substantial amount of their time researching (and none teaching) health economics: Michael Cooper at Exeter and Dennis Lees at Nottingham. None of the aforementioned economists is highly cited in our database. Weisbrod has several items, the highest scoring one coming 80th. Klarman has several, the highest place being well out of the top 1,000. Mushkin has but one (a 1999 Spanish lecture) also well out. Buchanan's one and only foray was well out as well, as was Lees. Cooper and the Jewkeses did not appear in the database at all. Sic transit gloria economisti!

Another signal talent also appeared on the scene in 1963. This was Martin Feldstein with his article on the application of econometrics to the National Health Service (Feldstein, 1963) which reached its apogee with the publication of his tour de force in 1967 (Feldstein, 1967). This text heralded the birth of health econometrics. Indeed, the book was used in some universities at the time as a text in applied econometrics. Although the article does not feature in our database, his subsequent work on physician services (Feldstein, 1970), hospital cost inflation (Feldstein, 1971) and welfare loss of 'excess' insurance (Feldstein, 1973) all pioneered the use of econometric methods – with substantial policy controversy tantalizingly spicing up the mixture.

Since then we have charted the course of health economics through its literature. The growth has been astonishing, well outrunning its initial stable-mate, the economics of education. Economists writing on health and health care have plainly become a great deal more specialized than was the case, though some of the most cited contributions have come from economists who would not consider themselves health economists at all. Some topics, such as 'Health and its value' and 'Economic evaluation', show no clear trend in popularity, while others display a clear trend: the topics 'Medical insurance' and 'Supply of health services' have lost favor, while the topics 'Determinants of health and ill-health' and 'Health statistics and econometrics' show a clear upward trend. While not analyzed in our paper, Rubin and Chang's (2003) analysis of a subset of our data confirms our suspicion that the frequency of joint authorships has increased over time; we speculate that much of that trend is due to multi-disciplinary collaborations. The geographic focus of health economics publications has broadened considerably over the last four decades, though central Asia, Africa, and the Middle East remain relatively under-researched by health economists.

There are few surprises among the most cited names in health economics – though the order is much determined by the choice of index. The ten most cited health economists are Cutler, Gruber, Newhouse, Pauly, Viscusi, Currie, Grossman, Sloan, Wagstaff and van Doorslaer. All citation indices probably tend to discriminate against those who go against the grain, which probably accounts for the relative lack of prominence of economists like Robert Evans, the father of 'supplier-induced demand' (Evans, 1974) and numerous well-aimed Canadian diatribes against his southerly neighbor. The highest scoring institutions (according to the *h*-index) are Harvard and the World Bank followed by MIT, Berkeley and Chicago, Pennsylvania, and Michigan and York (UK). Harvard is the least specialized of the top institutions in terms of topics studied; the World Bank and York are more specialized. The US dominates health economics, being home to 38 of the top 50 institutions. The UK has seven top-50 institutions, and Canada two. The most influential journal (in terms of aggregate citations) is the Journal of Health Economics followed by Health Economics. The Handbook of Health Economics and the Quarterly Journal of Economics are better cited, however, than either of these two leading journals in terms of the citation rates.

An interesting question might be whether health economics has fulfilled the promise diagnosed by Pauly in his reflections on Arrow's pioneering piece. 'Respectable'? Apparently so judging from the thorough permeation of policy circles by health economists and the ample flow of research funding (at least to those deemed 'respectable'!). 'Interesting'? Certainly, and not least because of the challenges that have had to be faced up to in adapting economists' 'standard economic models'. The question cries out "When is the standard 'purview' being embraced or rejected?" Our estimate is that, if the standard is taken as that of "competing, maximizing agents", there is much in health economics that challenges the usefulness of competitive models, or maximizing models, and that uses alternative maximands, especially in normative analyses. Health economics has yet, we think, to face up to many of the ethical dilemmas in health economics – how, for example, to embody in non-arbitrary and non-partisan ways some of the 'moral' issues mentioned by Pauly, especially in health care investment decisions and the design of insurance systems. Likewise, applied health economists have not really faced up to the implications, both positive and normative, of the assault by cognitive psychologists and experimental economists on the utilitarian (especially expected utility) foundations of the

economics core. But in this they probably cannot be held to be more accountable than applied economists of any kind.

Table 1: 300 most-cited publications in health economics, by topic

| Topic | Year | Title | First author | Journal / Edited volume | Citations | Rank |
|-----------------------|------|---|--------------------------|--|-----------|------|
| Health and its value | 2001 | The Colonial Origins of Comparative Development: An Empirical Investigation | Daron Acemoglu | American Economic Review | 4355 | 1 |
| Health and its value | 1993 | The RAND 36-Item Health Survey 1.0 | R. D. Hays | Health Economics | 826 | 28 |
| Health and its value | 1993 | The Value of Risks to Life and Health | W. Kip Viscusi | Journal of Economic Literature | 790 | 29 |
| Health and its value | 2003 | The Value of a Statistical Life: A Critical Review of Market Estimates throughout the World | W. Kip Viscusi | | 627 | 48 |
| Health and its value | 1995 | Multi-attribute Health Status Classification Systems: Health Utilities Index | David Feeny | PharmacoEconomics | 489 | 83 |
| Health and its value | 1985 | The Value of Safety: Results of a National Sample Survey | M. W. Jones-Lee | Economic Journal | 412 | 105 |
| Health and its value | 1997 | Disability-Adjusted Life Years: A Critical Review | Sudhir Anand | Journal of Health Economics | 399 | 111 |
| Health and its value | 2008 | How to Value a Life | W. Kip Viscusi | Journal of Economics and Finance | 367 | 127 |
| Health and its value | 1990 | Utility Functions That Depend on Health Status: Estimates and Economic Implications | W. Kip Viscusi | American Economic Review | 319 | 169 |
| Health and its value | 1992 | Quality-of-Life Assessment: Can We Keep It Simple? | D. R. Cox | Journal of the Royal Statistical Society: Series A (Statistics in Society) | 302 | 191 |
| Health and its value | 1997 | Measuring the Health of the U. S. Population | David M. Cutler | Brookings Papers on Economic Activity | 291 | 208 |
| Health and its value | 1999 | Preferences for Life Saving Programs: How the Public Discounts Time and Age | Maureen L. Cropper | Valuing environmental benefits: Selected essays of Maureen Cropper | 286 | 213 |
| Health and its value | 2003 | The Health of Nations: The Contribution of Improved Health to Living Standards | William D. Nordhaus | Measuring the gains from medical research: An economic approach | 286 | 213 |
| Health and its value | 2006 | The Value of Health and Longevity | Kevin M. Murphy | Journal of Political Economy | 254 | 263 |
| Health and its value | 2001 | Scarring: The Psychological Impact of Past Unemployment | Andrew E. Clark | Economica | 236 | 299 |
| Efficiency and equity | 2002 | Economic Status and Health in Childhood: The Origins of the Gradient | Anne C. Case | American Economic Review | 627 | 48 |
| Efficiency and equity | 2003 | Motivation, agency, and public policy: Of knights and knaves, pawns and queens | Julian Le Grand | | 533 | 65 |
| Efficiency and equity | 2006 | Poverty and Înequality in India: A Re- examination | Angus S. Deaton | Indian Economy since Independence | 417 | 100 |
| Efficiency and equity | 1997 | Socioeconomic Inequalities in Health: Measurement, Computation, and Statistical Inference | Nanak Kakwani | Journal of Econometrics | 415 | 103 |
| Efficiency and equity | 1998 | Mortality as an Indicator of Economic Success and Failure | Amartya K. Sen | Economic Journal | 413 | 104 |
| Efficiency and equity | 1997 | Income-Related Inequalities in Health: Some International Comparisons | Eddy van Doorslaer | Journal of Health Economics | 405 | 108 |
| Efficiency and equity | 2000 | On Limiting the Domain of Inequality | James Tobin | The foundations of the welfare state. Volume 1 | 403 | 109 |

Note: The starting point was our database of 33,000 publications in EconLit with a health JEL code. Google Scholar citation data were obtained for as many as possible (80 percent) in June 2011. The 300 most-cited publications were then assigned either one of the 12 topics listed in the appendix or a "topic not assigned" code. The latter included publications that were too general (some were actually textbooks) some had no health content despite the JEL code.

Table 2: Top 10 publications according to teachers and citations

| Rank | Teachers' ranking in 2004 | Ranking based on citations in 2011 |
|------|--|------------------------------------|
| 1 | Arrow (1963) | Acemoglu et al. (2001) |
| 2 | Manning et al. (1987) | Arrow (1963) |
| 3 | Torrance (1986) | Grossman (1972) |
| 4 | Grossman (1972) | Becker et al. (1994) |
| 5 | Newhouse (1996) | Rodrik et al. (2004) |
| 6 | Pauly (1968) (tied 5 th) | Therneau & Grambsch (2000) |
| 7 | Buxton et al. (1997) (tied 7 th) | DiMasi et al. (2003) |
| 8 | Cutler & Reber (1998) (tied 7 th) | Angrist et al. (1996) |
| 9 | McGuire & Pauly (1991) (tied 7 th) | Dasgupta (1993) |
| 10 | Harris (1977) | Torrance (1986) |
| 10 | Labelle et al. (1994) (tied 10 th) | |

Note: The teachers' ranking was based on an interview of members of the International Health Economics Association as reported in Culyer (2006). The starting point for the rankings based on citations in 2011 was our database of 33,000 publications in EconLit with a health JEL code. Google Scholar citation data were obtained for as many as possible (80 percent) in June 2011.

Table 3: Topics of most-cited 50 publications by decade

| | 1970s | 1980s | 1990s | 2000s |
|---------------------------------------|-------|-------|-------|-------|
| Health and its value | 3 | 1 | 4 | 2 |
| Efficiency and equity | 2 | 2 | 3 | 4 |
| Determinants of health and ill-health | 2 | 4 | 6 | 9 |
| Public health | 2 | 5 | 2 | 6 |
| Health and the economy | 5 | 4 | 5 | 4 |
| Health statistics and econometrics | | 1 | 5 | 9 |
| Demand for health and health care | 3 | 3 | 3 | 1 |
| Medical insurance | 9 | 3 | 4 | 3 |
| Supply of health services | 12 | 9 | 3 | 2 |
| Human resources | 6 | 4 | 3 | 3 |
| Markets in health care | | 3 | | |
| Economic evaluation | 1 | 2 | 5 | 3 |
| Total | 45 | 41 | 43 | 46 |

Note: The starting point was our database of 33,000 publications in EconLit with a health JEL code. Google Scholar citation data were obtained for as many as possible (80 percent) in June 2011. The 50 most-cited publications were then assigned either one of the 12 topics listed in the appendix or a "topic not assigned" code. The latter included publications that were too general (some were actually textbooks) some had no economic content despite being in EconLit, and some had no health content despite the JEL code.

Table 4: Rank correlations on author data

| | Publication count $(I^3 \alpha=0)$ | Total citations $(I^3 \alpha=1)$ | h -index (I^1) | Quadratic Influence Function (I^2) | $I^{3} \alpha = 0.5$ | Citations of most-cited publication |
|--|------------------------------------|----------------------------------|--------------------|--------------------------------------|----------------------|-------------------------------------|
| Publication count ($I^3 \alpha = 0$) | 1.000 | | | | | |
| Total citations ($I^3 \alpha = 1$) | 0.477 | 1.000 | | | | |
| h -index (I^1) | 0.376 | 0.678 | 1.000 | | | |
| $QIF(I^2)$ | 0.479 | 1.000 | 0.677 | 1.000 | | |
| $I^3 \alpha = 0.5$ | 0.554 | 0.991 | 0.696 | 0.991 | 1.000 | |
| Citations of most-cited publication | 0.399 | 0.991 | 0.660 | 0.991 | 0.967 | 1.000 |

Note: The starting point was our database of 33,000 publications in EconLit with a health JEL code. Google Scholar citation data were obtained for as many as possible (80 percent) in June 2011. Each listed author was given full credit for a publication in the case of a co-authored publication. An *h*-index of 10 means that the author has 10 publications to his or her name each of which has been cited at least 10 times. The quadratic influence function is defined in eqn (1). The measure \vec{I} is defined in eqn (2). All authors were included in calculating these (rank) correlations however few publications in health economics they had to their name.

Table 5: Top 100 health economists based on *h*-index over period 1969-2010

| Rank on h-index | Author | % publications not found in | I³ α=0 Publication count | Rank on I^3 with $\alpha=0$ | $I^3 \alpha = 0.5$ | Rank on I^3 with α =0.5 | <i>I</i> ³ α=1 Total citations | Rank on I^3 with $\alpha=1$ | h-index (I ¹) | I ² Quadratic influence | Rank on I ² | Maximum citations | Rank on maximum citations |
|-----------------|----------------------|-----------------------------|--------------------------------|-------------------------------|--------------------|----------------------------------|---|-------------------------------|---------------------------|------------------------------------|------------------------|-------------------|---------------------------|
| II-IIIQEX | | Google Scholar | count | | | | citations | | | function | | | citations |
| 1 | David M. Cutler | 14% | 114 | 2 | 629 | 1 | 6384 | 2 | 44 | 2.859 | 2 | 684 | 78 |

Note: The starting point was our database of 33,000 publications in EconLit with a health JEL code. Google Scholar citation data were obtained for as many as possible (80 percent) in June 2011. Each listed author was given full credit for a publication in the case of a co-authored publication. An h-index of 10 means that the author has 10 publications to his or her name each of which has been cited at least 10 times. The quadratic influence function is defined in eqn (1). The measure I^3 is defined in eqn (2). All authors were included in calculating the figures however few publications in health economics they had to their name.

Table 6: Top 100 institutions in health economics based on h-index

| | Institution | % not found in | $I^3 \alpha = 0$ | Rank | $I^3 \alpha = 0.5$ | Rank | $I^3 \alpha = 1$ | Rank | h -index (I^1) | I^2 | Rank | Maximum citations | Rank |

Note: The starting point was our database of 33,000 publications in EconLit with a health JEL code. Google Scholar citation data were obtained for as many as possible (80 percent) in June 2011. Each listed institution was given full credit for a publication in the case of a co-authored publication, but only the first institution was credited where an author listed multiple institutions. Institutional affiliations below the institution level were aggregated up to the level of the institution, so that for example publications originating from the Harvard School of Public Health were allocated to Harvard University along with publications originating from the Department of Economics at Harvard University. As explained in the text, only addresses with five or more articles to their name were retained for cleaning and aggregating. An *h*-index of 10 means that the author has 10 publications to his or her name each of which has been cited at least 10 times. The quadratic influence function is defined in eqn (1). The measure I^3 is defined in eqn (2).

Table 7: The 10 most cited publications of each of the top-10 institutions in health economics

| Institution | Authors | Type | Year | Journal | Title | Citations |
|-------------|--|-----------------|------|--|---|-----------|
| Harvard U | Dani Rodrik; Arvind Subramanian; Francesco Trebbi; | Journal Article | 2004 | Journal of Economic Growth | Institutions Rule: The Primacy of Institutions over Geography and Integration in Economic Development | 2033 |

Note: The starting point was our database of 33,000 publications in EconLit with a health JEL code. Google Scholar citation data were obtained for as many as possible (80 percent) in June 2011. Each listed institution was given full credit for a publication in the case of a co-authored publication, but only the first institution was credited where an author listed multiple institutions. Institutional affiliations below the institution level were aggregated up to the level of the institution, so that for example publications originating from the Harvard School of Public Health were allocated to Harvard University along with publications originating from the Department of Economics at Harvard University. As explained in the text, only addresses with five or more articles to their name were retained for cleaning and aggregating.

Table 8: Topical distribution of the most-cited 50 publications of the United States' top-5 institutions and Europe's top institution

| | Harvard U | World Bank | MIT | U CA, Berkeley | Chicago U | U York |

Note: The starting point was our database of 33,000 publications in EconLit with a health JEL code. Google Scholar citation data were obtained for as many as possible (80 percent) in June 2011. An h-index of 10 means that the author has 10 publications to his or her name each of which has been cited at least 10 times. The quadratic influence function is defined in eqn (1). The measure I^3 is defined in eqn (2). A normalized h-index of 20% means that 20% of articles in the journal have been cited at least 20 times.

Table 13: Top 25 edited volumes in health economics based on h-index

Note: The starting point was our database of 33,000 publications in EconLit with a health JEL code. Google Scholar citation data were obtained for as many as possible (80 percent) in June 2011. An h-index of 10 means that the author has 10 publications to his or her name each of which has been cited at least 10 times. The quadratic influence function is defined in eqn (1). The measure I^2 is defined in eqn (2). A normalized h-index of 20% means that 20% of articles in the journal have been cited at least 20 times.

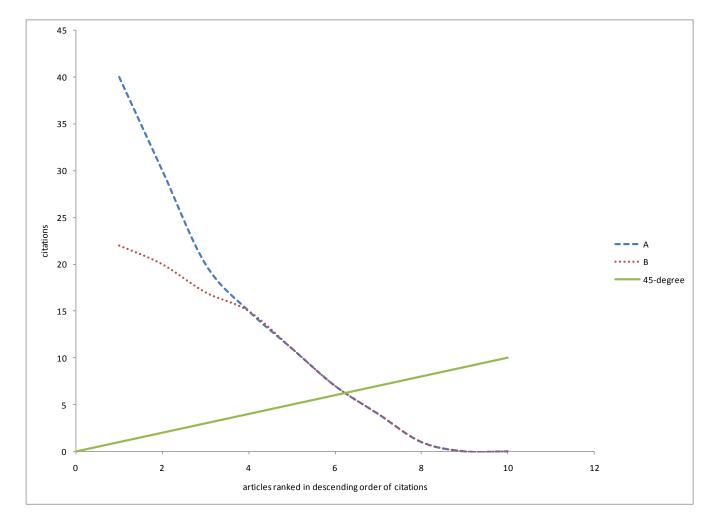

Figure 1: Measuring influence through citations (i)

Note: The chart show the hypothetical citation curves of two individuals A and B. The portfolios of each are ranked in descending order of citations. Both have an *h*-index of 6 meaning that A and B have 6 publications to their name each of which has been cited at least 6 times. The *h*-index is found by reading off either axis at the point where the citation curve intersects the 45-degree line.

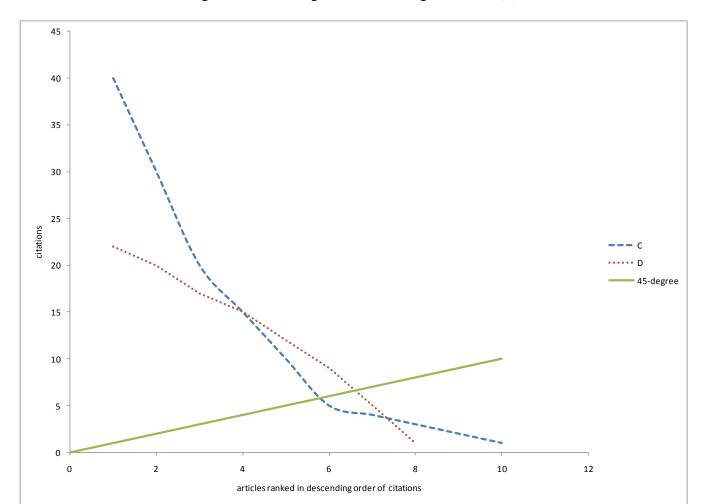

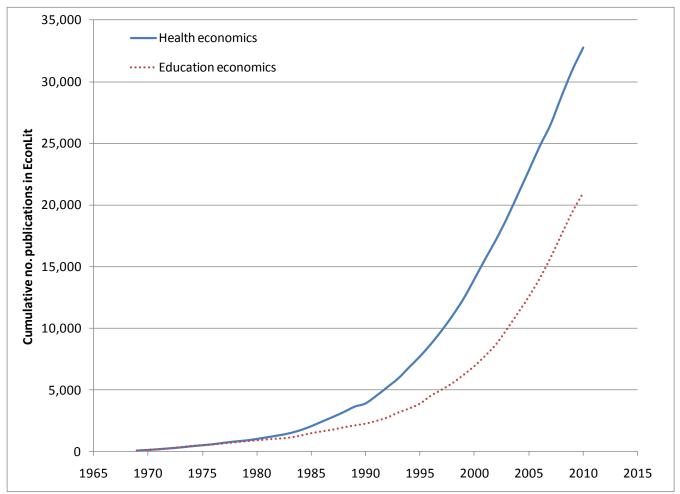

Figure 2: Measuring influence through citations (ii)

Note: The chart show the hypothetical citation curves of two individuals C and D. The portfolios of each are ranked in descending order of citations. D has an *h*-index of 7 meaning that he or she has 7 publications to his or her name each of which has been cited at least 7 times, while C has an *h*-index of 6. The *h*-index is found by reading off either axis at the point where the citation curve intersects the 45-degree line.

Figure 3: Cumulative numbers of publications in EconLit in health economics and education economics

Note: Health and education publications in EconLit are identified using the health and education JEL codes.

Note: The starting point was our database of 33,000 publications in EconLit with a health JEL code. The relative sizes of the title words reflect the frequency of their occurrence. The words "health", "care", "economic" and "analysis" have been removed, as have common words such as "the", "and", etc.

Figure 5: Top-150 title words in health economics articles in the 2000s

Note: The starting point was our database of 33,000 publications in EconLit with a health JEL code. The relative sizes of the title words reflect the frequency of their occurrence. The words "health", "care", "economic" and "analysis" have been removed, as have common words such as "the", "and", etc.

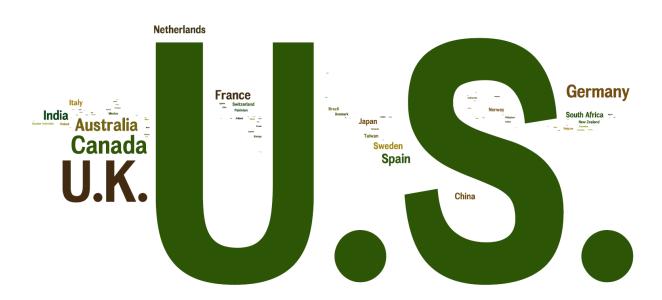

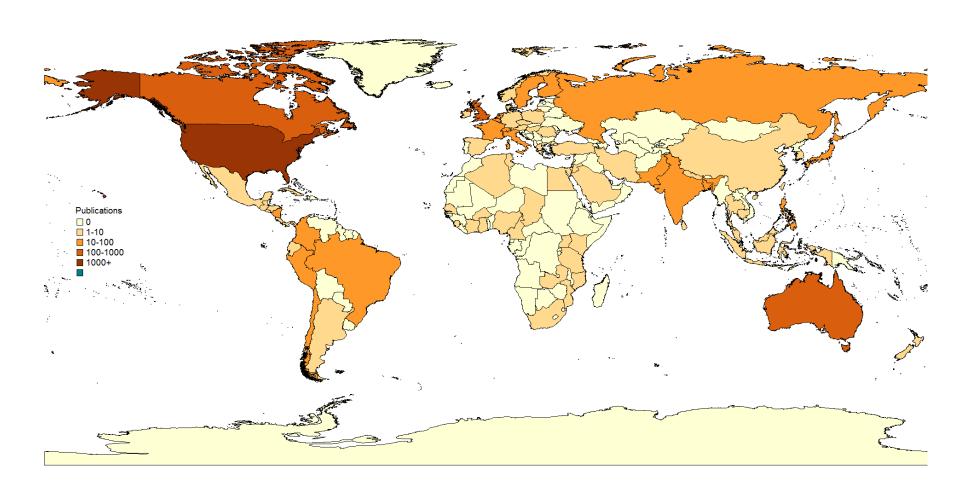

Figure 6: Country focus of health economics articles 1969-2009

Note: The starting point was our database of 33,000 publications in EconLit with a health JEL code. Each listed institution was given full credit for a publication in the case of a co-authored publication, but only the first institution was credited where an author listed multiple institutions. Institutional affiliations below the institution level were aggregated up to the level of the institution, so that for example publications originating from the Harvard School of Public Health were allocated to Harvard University along with publications originating from the Department of Economics at Harvard University. As explained in the text, only addresses with five or more articles to their name were retained for cleaning and aggregating. Institutions were then assigned a country. The size of the country's name reflects the frequency of its appearance in the author's country list.

Figure 7: Country focus of health economics articles 1969-89

Note: The starting point was our database of 33,000 publications in EconLit with a health JEL code. Each listed institution was given full credit for a publication in the case of a co-authored publication, but only the first institution was credited where an author listed multiple institutions. Institutional affiliations below the institution level were aggregated up to the level of the institution, so that for example publications originating from the Harvard School of Public Health were allocated to Harvard University along with publications originating from the Department of Economics at Harvard University. As explained in the text, only addresses with five or more articles to their name were retained for cleaning and aggregating. Institutions were then assigned a country.

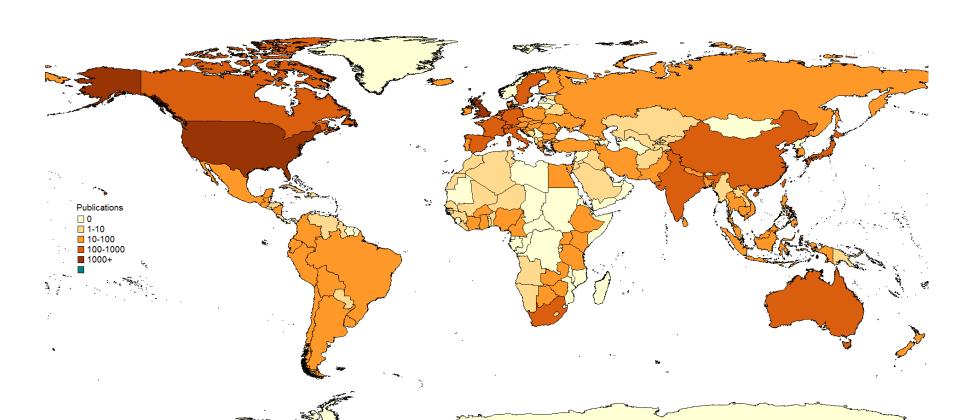

Figure 8: Country focus of health economics articles 1990-2009

Note: The starting point was our database of 33,000 publications in EconLit with a health JEL code. Each listed institution was given full credit for a publication in the case of a co-authored publication, but only the first institution was credited where an author listed multiple institutions. Institutional affiliations below the institution level were aggregated up to the level of the institution, so that for example publications originating from the Harvard School of Public Health were allocated to Harvard University along with publications originating from the Department of Economics at Harvard University. As explained in the text, only addresses with five or more articles to their name were retained for cleaning and aggregating. Institutions were then assigned a country.

Appendix: Topic classification scheme

1. Health and its value

Attributes of health; measurement of health; value of health; value of life; value of avoiding risk of ill-health; utility measures of health-related quality of life; stated and revealed preference methods of measuring willingness to pay; conjoint analysis.

2. Efficiency and equity

Welfare, efficiency, equity and possible conflicts; inequality and the socio-economic 'gradient'; evaluating efficiency at system level: international comparisons in the developed world; techniques for measuring equity and inequity; evaluating equity at system level: equity in financing arrangements; evaluating equity at system level: equity in service access and delivery; evaluating equity at system level: equity in the distribution of health; institutional arrangements for efficiency and equity; implications for health care financing and delivery systems in the developed world; centralization and decentralization in health care; the role and regulation of markets in developed countries.

3. Determinants of health and ill-health

The population health perspective; income and wealth; early determinants of lifetime health (genetics, parenting, schooling, peer effects); aging; occupational and workplace health and safety; addiction: tobacco, alcohol, drugs; the environment: air/water pollution, carcigens, other chemicals, allergens, radiation, etc; economic and social inequality as a determinant of ill-health; epidemics: AIDS, obesity, malaria; prevention, primary and secondary; chronic diseases; infectious diseases; social capital, cultural factors.

4. Public health

Public health technologies; public goods and public health; policies towards health and safety at work; health education; financing public health; public health and public behavior; interplay between public health and health care services; interplay between public health and other sectors; economics of public health policy.

5. Health and the economy

Global expenditure patterns and their determinants; public expenditure and health care; health in macro models; health and the trade cycle; health and labor force productivity; health and growth; health and economic development; health and employment/unemployment; health and social security; health, savings and investment; health and foreign trade; health and innovation/entrepreneurship.

6. Health statistics and econometrics

Administrative data and data linkage; collecting health data for econometric analysis; categorical data methods; count data; duration analysis; econometric evaluation by non-experimental methods; econometric evaluation with randomized experiments; econometrics in technology assessment; macro panels; models of health care costs; models for risk adjustment; panel data methods; productivity analysis; simulation methods and mixture models; spatial econometrics.

7. Demand for health and health care

Demand and need; utility and demand; demand for health as human capital; derived demand for health care; income and price elasticities; information asymmetries and agency relationships; externalities and publicness; supplier-induced demand.

8. Medical insurance

Demand for insurance (including long-term care, supplementary insurance); supply of insurance services; moral hazard, its control and trade-offs with risk-pooling; adverse selection and cream skimming; tax-financed health care systems; tax policy, exemptions, personal subsidies and health care financing; private and public systems of health insurance; welfare effects of 'excess' insurance and the trade-off with internalizing externalities; insurance effects on health care providers; issues in coverage: services covered, individual eligibility.

9. Supply of health services

Monopoly and competition in health care supply; models of health care institutions (hospitals, nursing homes; for-profit, non-profit); care in the community: long term care, informal care; ambulance services; managed care; health care production functions; cost functions; economies of scale and scope; quality of care; regulation and price controls; the pharmaceutical and medical equipment industries.

10. Human resources

Models of professional behavior(s); doctors; nurses; other health professionals; health care managers; professional labor markets; training, continuing training and human capital; licensing; remuneration – fee for service, salary, capitation; doctors as entrepreneurs and employers; professionals and research; forecasting demand and supply.

11. Markets in health care

Information and markets; market failure; internal markets; rationing; waiting; discrimination; public goods and externalities; regulation (entry/exit); price controls; institutional subsidies; welfare economics and system evaluation; comparative systems.

12. Economic evaluation

Principles of Cost-Benefit Analysis, Cost-Utility Analysis, CEA, Cost-Consequences Analysis and Cost Analysis; techniques of CBA in health and health care; techniques of CUA and CEA in

health and health care; techniques of CCA and CA in health and health care; decision theoretical approaches; pharmacoeconomics; economic evaluation of clinical devices; economic evaluation of public health interventions; outcome measures and their interpretation; evidence, efficacy and effectiveness; Health Technology Assessment; study design; risk and uncertainty; discounting; sensitivity analyses; modeling; systematic reviews and meta-analyses.
