Trust and Fiscal Performance: A Panel Analysis with Swiss Data

Summary

Citizens are willing to abandon their short-term financial interest in free-riding considerably, if governments act in their interest, if procedures of the public decisions-making process are felt to be fair and if other fellow-citizens have to contribute also an adequate share to the community. In such a situation trustworthiness of a government and trust in a government is high. This paper provides empirical evidence that trust is crucial for fiscal performance using data for the full sample of Swiss cantons over the 1981-2001 period. In cantons with high levels of trust, the level of indebtedness is significantly lower. Trust supports fiscal discipline. In order to get a useful approximation for mutual trust among citizens and between citizens and their representatives, we use information from direct voter participation on political issues (initiatives and public referenda) held in Swiss state (cantonal) governments. Electoral support of government proposals reveals an important aspect of trust in a real world setting. Hence, our trust variable measures the behavior at the ballots thereby reducing possible subjective biases derived from surveys and questionnaires.

Keywords: Trust, Social capital, Fiscal performance, Indebtedness

We are very grateful to Jakob de Haan, Martin Paldam and Gebhard Kirchgässner for their helpful comments and suggestions, Alexander Trechsel as well as the cantonal statistical offices for providing us with information on the data source of cantonal ballots and Justina Fischer. The authors have additionally benefited from comments of participants of the Annual Meeting of the Public Choice Society 2005 in New Orleans and the Annual Meeting of the European Public Choice Society 2005 in Durham. Financial support from the Max Geldner-Stiftung, the Janggen-Pöhn-Stiftung, the FAG (Freiwillige Akademische Gesellschaft, and the University of Basel (Fonds zur Förderung des Akademischen Nachwuchs) is gratefully acknowledged. The authors are responsible for all remaining shortcomings in the article.

Social capital is a new field, suffering from a great lack of good, reliable data. Both time series and cross-country evidence are missing. In the meantime much speculation is going on ... it is hopefully clear that social capital is a promising concept, which can be operationalized by relatively simple measurement. However, it will take some time and a lot of work has to be done before it is known if social capital can deliver what it promises (p. 649).

Paldam (2000, p. 649)

1. Introduction

Several OECD countries have accumulated large government debts over the last 30 years. Very much the same applies for sub-federal governments. Why do we observe large debts in certain governments but not in others? An explanation to that question can be found looking at the institutional framework of jurisdictions. They are particularly important for fiscal policy decisions as fiscal institutions create the environment, the incentives, the rules, the regulations and the constraints under which budgets are drafted, approved, and implemented. Fiscal institutions can promote fiscal discipline if properly designed while an institutional framework that results in soft budget constraints provides incentives for loose fiscal discipline. These rules greatly vary over governments and thus provide a reasonable explanation for cross-section variations in debt levels (Alesina and Perotti 1995, Poterba and von Hagen 1999 or Persson and Tabellini 2001).

According to Buchanan (1980) we can broadly distinguish between quantitative and procedural institutions. Quantitative rules entail tax and expenditures limitation laws, debt brakes and other formal restraints to balance the budget. As empirically shown by Bohn and Inman (1996), Poterba (1997) or Shadbegian (1998) such budget rules can effectively support the fiscal discipline of policy makers. Procedural institutions define how property rights over political decisions are acquired, and who can exercise them. As shown by Persson and Tabellini (2003) the

constitutional design of the regime type and the electoral rules also shape fiscal policy decisions to a significant extent.

However, it will never be possible to design a constitution and to establish a framework of quantitative and procedural institutions that answers all future questions of a society. Hence, in all those cases where there is a degree of uncertainty, trust becomes a crucial aspect. Guerra and Zizzo (2003) point out that “without uncertainty, trust is not a significant issue because certainty means the outcome will be the same whether or not a trusting act was involved” (p. 3). Mutual trust in the case of uncertainty reduces transaction costs and makes the institutional architecture to work smoothly (Putnam 1993, 2000; Fukuyama 1995). Trust can be seen as the social capital of a society. Alesina and La Ferrara (2002) point out that social capital and trust lead to better functioning of public institutions and help in case of market imperfections. Consequently, trust should be a crucial aspect in explaining fiscal policy decisions. Moreover, it is reasonable to assume that deep-seated social capital fosters fiscal discipline.

The paper concentrates on the relationship between public debts and trust in the government using the full sample of Swiss state governments over the 1981-2001 period. We measure trust as the ratio of concurrence between Swiss state (cantonal) government’s recommendation for an issue put to a vote and the actual outcome at the ballot, but also taking into consideration the number of ballots per year to measure the level of citizens’ chance to express their preferences. Ballots help to increase governmental accountability, so that the government is forced to be responsive to citizens’ preferences and the underlying “social contract” at large, which leads to a higher level of fiscal discipline. Our hypothesis states that more trust in government, measured as the electoral support of government decisions is a signal for a stronger social cohesion between the government and the electorate and within the electorate, which in turn results in sounder fiscal policy decisions. The results indicate that we find a fairly robust negative relationship between trust in the government and public debt. Thus, we conclude that fiscal policy is

strongly influenced by individuals' trust in the government. A higher level of citizens' trust in the state leads to a stronger fiscal discipline.

To our knowledge, our paper provides some novelties compared to previous studies: First, empirical studies in the social capital literature often work with cross-country data. However, it is very difficult to draw conclusions from cross-cultural comparisons. Institutional and Cultural frameworks typical for specific countries might influence trust. The problem is that such features cannot always be controlled in a satisfactory manner. Our study on the other hand, focuses on *within* country data at the state (cantonal) level and thus allows to better isolate the impact of trust. Second, social capital is usually measured by survey data asking individuals questions about trust (social trust, agreement to the statement whether most people can be trusted) and the level of participation in voluntary organizations. Rose-Ackerman points out that measures of generalized trust “are very difficult to interpret and to translate into concrete proposal” (p. 3). Glaeser et al. (2000) criticize that these survey questions are interesting but “also vague, abstract, and hard to interpret” (p. 812). Furthermore, it cannot be assumed that attitudinal questions predict observable behavior. Even Putnam (1995) is aware of it stressing that it would be desirable to have behavioural indicators of social capital. Thus, in this paper we search for a social capital proxy that measures individuals' *observable behavior* rather than their attitudes or statements. Our behavioral trust variable that measures the behavior at the ballot reduces possible subjective biases derived from survey questionnaires. Third, a huge amount of studies work with cross-sectional data. Our panel analysis, covering a long period of more than 20 years, allows exploiting time variation in trust, too.

The remainder of the paper is as follows: First, we provide a quick overview of the literature on social capital and trust. Then, we develop a concept of trust revealed in a real world setting and present some evidence of the level of trust among Swiss cantons over the last twenty

years. In section five follows the empirical implementation of the impact of trust on fiscal performance while section six offers some concluding remarks.

2. Overview: Social Capital and Trust

Social capital has been studied at length by many different disciplines. It has advanced to an important concept in social sciences, enforcing the interdisciplinary social discourse among researchers. The rapid growth of the social capital literature underlines a widespread unease with the standard explanations for the differential political and economic performances not only across nations but also across sub-national jurisdictions (Ostrom and Ahn 2003). Many studies in the last ten years tried to check to which extent social capital can be seen as an important omitted factor in previous studies.

The political scientists Almond and Verba (1963) have been among the first who intensively investigated the concept of social capital. Many years later, there has been a renewed interest in the social basis of political and economic life thanks to the work by researchers such as Putnam (1993) and Fukuyama (1995). Social capital advanced to an important research agenda in political sciences. Putnam (1993) claims the importance of social capital for the effective governance of democracy. He defines social capital as “features of social organization, such as trust, norms, and networks that can improve the efficiency of society by facilitating coordinated actions” (p. 167). Many authors have singled out social capital as an important feature of productive social relationships (see, e.g., Gambetta 1988, Hardin 1993). Sociologists have also intensively investigated the concept of social capital. Key figures at the beginning were Bourdieu (1979) and Coleman (1988, 1990). They both have strongly influenced the social capital literature focusing on individuals and small societal units. Portes and Mooney (2002) point out that the most widely accepted definition of the term social capital in sociology is the “the ability to secure resources by virtue of membership in social networks or larger social structures” (p. 305).

Also economists increasingly pay attention to the concept of social capital and trust. Many studies have been published in leading economic journals (see, e.g., Knack and Keefer 1997, Zak and Knack 2001, Glaeser et al. 2000, Alesina and La Ferrara 2002). For example, Knack and Keefer (1997) tested the impact of civic duty and trust on growth and investment rates in a cross section analysis. They find a strong and significant positive relationship between social capital variables and economic growth. Looking at the public finance literature, Slemrod (1998) argues that the social capital derived from the willingness to pay taxes voluntarily lowers the cost of the operating government and of equitably assigning its cost to citizens. Social capital has also attracted non-academic institutions such as the World Bank, which developed a Social Capital Initiative focusing mainly on developing countries and investigating the practical relevance of this concept. Grootaert (2001, pp. 10-11) stresses that there are three major views on social capital: First, the concept developed by Putnam (1993) interpreting social capital as a social network, as networks of civic engagement facilitating coordination and cooperation. Second, Coleman's (1988, p. 598) approach defines social capital as "a variety of different entities", consisting of some aspects of social structure and facilitating certain actions of actors. This allows taking into account not only horizontal but also vertical social relationships. The third concept considers the social and political environment that enforces norms and shapes social structures.

According to Paldam (2000, p. 630), there are three families of social capital concepts: trust, cooperation and network. He points out that "most people build *trust* in and *networks* to others and come to *cooperate* with them" (p. 629). Trust and cooperation are closely related. He defines social capital as the ability of a person to work voluntarily together with others, for a common purpose in groups and organizations (p. 635). But what exactly is trust? There are different conceptualizations of trust. Uslaner (2002) differentiates between moralistic trust and strategic trust. Strategic trust reflects "expectations about how other people *will* behave" (p. 23). On the other hand, "moralistic trust is a statement about how people *should* behave. *People ought to*

trust each other” (p. 23). Thus, moralistic trust works also in the absence of reciprocity. In a further step, Uslaner (2002) points out that the distinction between strategic and moralistic trust is a “continuum from particularized to generalized trust” (p. 26)¹. Generalized trust is the belief that most people can be trusted and thus does not depend upon specific individual or group characteristics. On the other hand, particularized trust is the belief that only a specific individuals or groups can be trusted². While particularized trust relies strongly upon experiences (strategic trust), moralistic trust is the foundation of generalized trust. Uslaner points out that the “central idea distinguishing generalized from particularized trust is how inclusive your moral community is” (pp. 26-27).

If trust is a multidimensional concept, not only the analytical distinction between particularized and generalized trust is relevant, but also the empirical one. To measure generalized trust, many researchers have relied upon the following survey question derived by Rosenberg (1956) many years ago: “Generally speaking, do you believe *most people* can be trusted or can’t you be too careful in dealing with people?”. It indicates that not only well-known people are trusted but also strangers. Particularized trust can be measured using group categories to classify people in their own network, for example, asking survey questions regarding respondents’ trust in their neighbors, friends, co-workers or family and club members. Contrary to previous studies we try to find with field data a proxy that measures individuals’ *observable* behavior rather than measuring trust with survey data. Observing the behavior at the ballots reduces possible subjective biases derived from survey questionnaires. Glaeser et al. (2000) combined experiments and sur-

¹ See also Granovetter (1973) who also differentiates between generalised trust and specific trust.

² Other researchers use similar concepts, for example, thin and thick trust, bonding and bridging social capital, personal and social trust (see, e.g., Williams 1988, Putnam 1993, 2000, Rahn and Transue 1998).

veys together and find that standard attitudinal questions do not predict subject choices in their experiments³.

Our investigation in this paper grounds basically on the third concept, which takes the more formalized institutional relationship between state and citizens at the vertical level into account. As trust is a multidimensional concept, we restrict our focus on a specific dimension: citizens' political trust. This is in line with Rothstein (2003), who argues that the explanation of social capital is much more grounded in political instead of sociological variables.

3. Trust in Politics

There are three ways in which trust affects government performance according to Knack (1999). First, trust broadens government accountability. Policy decisions have to be responsive to the preferences of a large part of the population. Knack (1999), for example, provides empirical evidence, that US states with a higher social capital significantly perform better than the other states. Second, trust can facilitate an agreement, where political preferences are polarized. Third, social cohesion in a society is a breeding ground for innovations in politics. In general, the space for innovations is greater if trust between members of a society is established. If new challenges have to be tackled, governments with high social capital are more flexible in adapting to the new circumstances than regions with widespread interests. Little political polarization in regions with a strong social cohesion makes it easier for the government to implement policies preferred by the electorate. Moreover, little social fragmentation in the society reduces the asymmetry between spending claims of different interest groups and taxing decisions. Therefore, a more homogenous citizenry supports fiscal discipline.

³ However, questions about trusting attitudes seem to predict trustworthiness. The authors conclude that "to determine whether someone is trusting, ask him about specific instances of past trusting behaviors. To determine whether someone is trustworthy, ask him if he trusts others" (p. 840).

Government accountability can be seen as the most important aspect of trust with respect to fiscal performance. Engagement, involvement and participation in political and public issues by a large part of the electorate are an important feature to hold politicians and bureaucrats accountable. In Putnam (2000, p. 346) words: “Citizens in civic communities expect better government, and (in part through their own efforts) they get it ... if decision makers expect citizens to hold them politically accountable, they are more inclined to temper their worst impulses rather than face public protests”. Political participation in ballots allows citizens to discuss the topics and helps to improve political awareness. Thus, the government knows that citizens are discussing and monitoring their behaviour, which will produce the incentive to govern more effectively. It also offers citizens the possibility to articulate themselves and thus to visualize their preferences which contributes to a more effective governance, too. As the government is better aware of citizens’ preferences, policies will better reflect citizens’ needs (see Boix and Posner 1998).

Game theory and experimental findings have shown that trust facilitates the co-operation between the actors and allows reaching superior social outcomes. However, Boix and Posner (1998) criticize that such an investigation “leaves us without an explicit articulation of the mechanism by which the ability of people in society to co-operate affects the performance of the governmental institutions (p. 689)”. Our study takes this into account by trying to investigate the interaction between citizens and their state. Trust in politics measures the level of confidence citizens have in their political leaders or institutions. In these cases trust is close to “approval” and “validation” revealing a widespread belief that the government is carrying-out those actions that are in the interest of the citizenry (Slemrod 2003). To capture such an interpretation of trust, contrary to previous studies, we measure trust as the ratio of concurrence between Swiss state (cantonal) government’s recommendation for an issue put to a vote and the actual outcome at the ballot, but also taking into consideration the number of ballots per year to measure the level of citizens’ chance to express their preferences. Thus, we have a trust proxy that measures indi-

viduals' *observable* behavior interacting with the government, rather than measuring trust with survey data.

If the citizens and the authorities interact in a sense of collective responsibility influenced by the institutional structures, then the system may be better governed and its policies may be more effective. Trust promotes effectiveness through its impact on governments' behavior. In our paper we focus on public debt as dependent variable. It is reasonable to argue that a prudent debt management and thus a certain level of fiscal discipline can be seen as a proxy for governmental performance. Ballots help to increase governmental accountability, so that the government is forced to be responsive to citizens' preferences and the underlying "social contract" at large, favoring a higher level of fiscal discipline. Trust in government is a signal for a stronger social cohesion between the government and the electorate and within the electorate, which in turn results in sounder fiscal policy decisions. Thus, the following hypothesis can be derived:

Hypothesis: The stronger trust is established in a jurisdiction the better its fiscal performance.

4. Measuring Trust in the Swiss Cantons

The political process in Swiss cantons offers a fruitful database to measure trust. In our case, we use information from direct voter participation on political issues by voter initiatives and public referenda as an approximation for mutual trust among citizens and between citizens and their representatives. Several aspects of trust are of importance in the process of direct voter participation in Switzerland. To launch a voter initiative or to veto government decisions by a popular referendum represent possibilities to reveal distrust in the government. Even if we assume that the government is benevolent, such instruments can be useful in case the governments fall out of step and make mistakes in interpreting voters' preferences (Matsusaka, 2004). This may happen

as a result of strong political polarization on a specific issue or high information costs. Contrarily, if social cohesion in the electorate is strong, it is easier for the government to implement policies according to the preferences of the electorate. They make fewer mistakes in interpreting the voters' preferences. Hence, if social cohesion is strong, fewer decisions by the government will be vetoed and fewer voter initiatives will be successfully launched. As a consequence, support of government decisions by the electorate is a useful indication of trust and social capital among members of a society.

Assuming now that the government is not benevolent in any case, direct voter participation in this case is a possibility to control the discretionary power of politicians. Voter control can help to limit the abuse of political power by selfish politicians. As citizens cannot completely foresee the preferences of their incumbents, elements of direct democracy empowers them with an instrument to control their government. This also has an ex ante effect on policy formulation by the elected incumbents since they always have to take into account a possible voter intervention. If politicians should try to abuse their policy discretion, voters will increasingly reject the governments' proposals. Thus, the support of government decisions by direct voter participation is also a measure of trust in government. If government proposals acknowledge common interests, voters will support the trustworthiness of their incumbents at the ballots.

Table 1: Ballots in all 26 Swiss cantons from 1981 to 2001	
Number of ballots	3100
Average number of ballots per year	148
Average number of ballots per canton	119
Lowest value (number of ballots)	22 (Jura)
Highest value (number of ballots)	285 (Zurich)*
Ratio of accepted government proposals	75.7 %
Highest value (Ratio of accepted government proposals)	94.3 % (Appenzell a. Rh.)
Lowest value (Ratio of accepted government proposals)	37.7 % (Jura)

* In the town-meeting canton Glarus 294 ballots were held.

In order to take both aspects of trust into account – trust among members of a society and trust between principal and agent – we collected data from all cantonal ballots held between 1981 and 2001 in all 26 Swiss cantons⁴. As can be seen in Table 1, 3100 cantonal ballots were held while 75.7 % of them succeeded in the sense of supporting the government proposals. The variation goes from Jura with a ratio of 37.7 % to Appenzell a. Rh. with a ratio of 94.3 % accepted government proposals. Interestingly, the number of ballots held varies quite a lot among cantons.

The reason is that some cantons offer much broader possibilities of voter participation than other cantons (see Feld and Matsusaka 2003 or Feld, Schaltegger and Schnellenbach, 2004). In order to take this institutional variation into account, we use state (cantonal) intercepts in our regression analyses since the institutional provisions on direct legislation hardly changes over time. However, the number of ballots held does not only give us information on the institutional variation but also on mutual trust. This is important in our case because the mere acceptance rate of ballots held during a year does not cover this special aspect of trust. More ballots imply a higher validation of policy choices by the government. Higher validation or shorter intervals between ballots is of importance when preferences of the electorate are changing or when there is uncertainty about preferences on a concrete policy project (Matsusaka 2004). Ballots provide addi-

⁴ No distinction between initiative and referendum has been done to measure both horizontal and vertical trust.

tional information for the government, which in turn enriches the decision-making process⁵. Thus, we construct our trust measure by the ratio of at the ballots accepted government proposals multiplied with the number of ballots held (acceptance X validation). This particular measure of trust allows us to incorporate both aspects of trust: Acceptance of government decisions and validation of government decisions. We include both measures in our trust variable, as they are not independent of each other. The validation of government decisions fosters acceptance of government decisions offering individuals the change to express their preferences. Thus, preferences of the people bearing the costs and benefits of government actions are visible which fosters citizens' trust. On the other hand, a higher acceptance of government decisions preserves government's interests to use ballots as an instrument and thus preserves the validation of government decisions⁶. This makes it useful to include both aspects in one variable in our model.

As Figure 1 shows trust varies considerably among cantons over the 1981-2001 period. The lowest value accounts for 0.57 represented by canton Jura while the highest value with 13 belongs to the canton Glarus. Similarly, there is a variation of trust over time as can be seen in Figure 2. With 3.615 the lowest value of trust is observed in 2001 while in 1988 trust was highest with a value of 5.75. Such a strong variation among cantons as well as over time allows exploiting *within*-country variation to identify effects of trust on governments' fiscal performances. It is also important to note, that the correlation between real GDP-growth and trust is only 0.0323, indicating that our measure is not just reflecting subjective well-being or perhaps even government's general popularity, which has been found in many empirical studies to be influenced by economic development⁷. In general, a multivariate analysis conducted in the next section will allow isolating the impact of trust on public debt.

⁵ In general, previous studies have shown that repeated interactions or a higher level of familiarity facilitate trust (see, e.g., Glaeser et al. 2000, Alesina and La Ferrara (2002).

⁶ This arguments is supported looking at the level of correlation between the variables. Furthermore, it should be noticed that using it as one variable leads to slightly better predictions.

⁷ For an overview see e.g., Pickup (2004).

5. Empirical investigation

In order to test whether trust fosters fiscal discipline, we propose the following baseline equation:

$$DEBT_{it} = \alpha + \beta CTRL_{it} + \zeta TRUST_{it} + TD_t + CD_i + \varepsilon_{it} \quad (1)$$

where i indexes the 26 cantons in the sample, $DEBT_{it}$ denotes the cantonal debt-levels per capita and per GDP over the 1981-2001 period and $TRUST_{it}$ is our indicator for trust described in the previous section. The regression contains also several control variables $CTRL_{it}$ like GDP per capita, share of urban population, share of workforce, share of population with higher schooling, share of unemployed, share of pensioners, share of pupils, population and a variable for the share of German speaking population in a canton. In order to control for time as well as cantonal in-

variant factors we include fixed time TD_t and fixed cantonal CD_i effects. ε_{it} denotes the error term.

In Table 2 and 3 we present three different kind of empirical methodologies: pooling, random effect and fixed effect regressions using cantonal debt-levels per capita (Table 2) and debt levels per GDP (Table 3) as dependent variables. In the pooled estimations we present the *beta* or *standardized* regression coefficients to compare the magnitude and thus to see the relative importance of the used variables. To get robust standard errors in the pooled estimations, we also used the Huber/White/Sandwich estimators of standard errors. To check which one is most suitable, we perform the Lagrangian Multiplier (LM) test (see Breusch and Pagan 1980) to test the random effect versus the pooling model and the Hausman specification test (see Hausman 1978) to compare the fixed effect versus the random effect model. The LM test indicates that the null hypothesis is rejected at the 1% significance level for both dependent variables. This suggests that pooling regression is less suitable than random effect regression. The Hausman test shows that the null hypothesis is rejected at the 5% significance level in Table 2 and rejected at the 1% significance level in Table 3. This suggests that it is more appropriate to use fixed effect models. Thus, for all the following extensions we present fixed effect regressions.

As can be seen by the multivariate analysis trust has a statistically significant negative impact on fiscal discipline (public debt) in all the regressions presented in Table 2 and 3, controlling for other determinants. Thus, our hypothesis finds strong empirical support looking at Swiss cantons over the periods 1981-2001. However, it can be criticized that institutional differences reflect long-standing differences in voters' trust towards the government. To check whether this argument holds, Appendix D presents estimations controlling for democratic participation rights. The used direct democracy index reflects the extent of direct democratic participation (1= lowest

and 6 highest degree of participation) at the cantonal level.⁸ As can be seen in most of the cases, the variable TRUST remains statistically significant after controlling for democratic participation rights. A higher level of direct democratic participation rights has also a significantly negative effect on public debts. Appendix D indicates a relatively strong quantitative effect. In general, it should be noticed that there is a relatively high correlation between trust and the index of direct democracy ($r=0.42^{***}$, significant at the 0.01 level), which may explain the lower effect of the TRUST variable. Our TRUST variable also takes into account the number of ballots held and thus controls for institutional variation. Furthermore, trust and direct democratic participation rights are not independent of each others. A higher level of direct democracy may foster trust as it imposes credible constraints on politicians and public officials. Trust is then a rational response to it (see Rose-Ackerman 2001). Sztompka (1999) points out that “the more there is institutionalized distrust, the more there will be spontaneous trust” (p. 140). Not surprising, in most of the cases the real GDP per capita reduces public debts significantly and sizeable, too. On the other hand, the share of urban population pushes up debt levels. This points to a higher governmental willingness to increase public debts in urban areas, which may be caused by specific problems of central cities like social heterogeneity. The provision and maintenance of central city infrastructure such as higher education, traffic, public health, public security or cultural facilities require high government revenue for the central city. At the same time, the tax bases in central cities are sensitive to high tax burdens. People react to tax incentives and move from the center to nearby local communities where the tax burden is lower. The asymmetry of spending claims and revenue capacity is often seen as a major driving force for problems of fiscal discipline in urban jurisdictions (Frey 1990, Brueckner 1983). Socio-demographical factors such as

⁸ The index includes the four legal instruments: the popular initiative to change the canton’s constitution, the popular initiative to change the canton’s law, the compulsory and the optional referendum to prevent new law or changing of a law and the compulsory and the optional referendum to prevent new state expenditure. The index is based on the degree of restrictions in form of the necessary signatures to use an instrument, the time span to collect the signatures and the level of new expenditure which allows to use the financial referendum (for a detailed discussion see Stutzer 1999).

the share of elderly and the share of pupils expectably push up debt-levels, too. These two groups only perceive a small fraction of the initiated costs eventually creating pressure for higher government spending. In addition, especially pensioners have an incentive to finance public services by deficit spending in order to postpone the costs to future generations (Meltzer and Richard 1981). The language variable is significantly negative indicating that the German speaking population cares more about fiscal discipline than their French and Italian speaking counterparts. The result is very much in line to the results in federal ballots and the behaviour of members of parliament from the roman part of Switzerland. The other control variables have not a robust and significant impact on public debt. In particular, there seems not to be a significant positive impact of better educated citizens on fiscal discipline. Obviously, better educated voters do not demand a more fiscally prudent government, which is somewhat surprising. One could have thought of a “supply side” effect since better educated citizens provide a larger tax base which in turn may make it easier to offer higher salaries to the public servants and also provide a larger pool of talents from which the government can recruit (Knack 1999).

In addition, we have included a variable capturing the degree of centralization of canton governments in Switzerland to check the sensitivity of our results. As shown by Shadbegian (1999) and other researchers for US states and by Feld, Kirchgässner and Schaltegger (2003) and Schaltegger (2003) for Swiss cantons government centralization favors the size of government. De Mello (2004) shows that fiscal decentralization also strengthens social capital in a cross-country study. Thus, it is not surprising that in our analysis government centralization is of high explanatory power for the level of government indebtedness, too. Note that also after including government centralization, trust remains an important and significant feature in explaining fiscal performance of governments.

Next, proprietors of houses have made a commitment to their jurisdiction by voluntarily increasing their opportunity costs for the exit option to migrate to another jurisdiction. This can

be seen as an alternative measure of trust in government⁹. However, the inclusion of the share of housing proprietors as a further regressor in the equation does not significantly increase the explanatory power of our public debts regressions.

Other institutional variations in Swiss cantons that do hardly vary over time are not included in our regressions since state (canton) dummy variables have been included. The canton dummies would render these institutional feature variables insignificant, anyway.

Table 4 differs from the previous tables in using instruments for our trust variable. Evaluating the direct effect of trust on fiscal performance in a setting where unobserved voter prefer-

ences might affect both trust and fiscal performance requires an instrumental variable technique to separate the impact of trust from the underlying voter preferences. A suitable instrument must be contemporaneously uncorrelated with the error term but must be highly correlated with trust. In our case, we use the number of votes as an instrument. Conceivably, in cantons in which voters have frequent possibilities to reveal their trust, trust will be more likely. Now, to test for possible endogeneity of trust a Hausman test is carried out in two steps. First, we regress the number of votes on trust including all other regressors from equation (1). The number of votes is highly significant in explaining trust, as expected. Second, we take the obtained residuals from that regression and include them in the original regression of equation (1). Since the coefficients of the included residuals are not significant (t-value of -0.187), trust can be considered as an exogenous variable. Thus, unsurprisingly the coefficients of the trust variable in the two-stage least square estimations in Table 4 do hardly change from those obtained in the ordinary least square regressions. This suggests that there is not much of a reverse causation from government debt to trust. We cannot observe that in the 2SLS regressions the coefficients for our trust variable are smaller than the ones estimated using OLS, what other would indicate that reverse causation may bias the OLS coefficient for trust upward (see Knack 1999). In addition, reversed causality is unlikely in our case from a theoretical point of view: at the time when voters go to the polls, data on public debts of the current year are unknown and will usually be published not before the following year.¹⁰

As can be seen in Appendix C two cantons are considered as outliers. The cantons Basel-Stadt (BS) as well as Geneva (GE) have a relatively and extraordinary high level of indebtedness. In the following, in order to check the robustness of the results, we take these two cantons out from our sample (excluding outliers). In Table 4, columns two and four present the results.

¹⁰ According to a yearly conducted survey on behalf of the Swiss Federal Department of Finance, the electorate is relatively well informed on public finances. In 2004 for example, 35 % of all the 1516 interview participants have estimated the accumulated level of debt for the federal level correctly (the interviews have been conducted by Demoscope, a professional institute on market research in Switzerland).

The coefficients of the trust variable remain significant even after excluding outliers indicating that our basic hypothesis is supported.

♠ denotes the two stage least square regressions. Instrument for trust is the number of votes.

♣ denotes regression after excluding the values of the canton Basel-Stadt (BS) and the canton Geneva (GE), which are considered as outliers (see Appendix C).

♥ There is a high simple correlation between the two regressors share of Protestants and share of Catholics (-0.921). However, eliminating either the former or the latter variable from the regression hardly changes the estimated coefficients as well as their significance level.

In the next step, we control for the religious composition of the cantons. Putnam (2000) recognizes the religion denomination as an important factor in building social capital. Knack (1999) finds a high correlation between trust and the mainline Protestants in the US states. Hence, religious composition may serve as a good instrument for trust. In fact, La Porta et al. (1997) and Knack (1999) both use religious composition to instrument for interpersonal trust. However, in our case there is only a weak simple correlation between trust and the share of Protestants (0.394) or share of Catholics (0.348). A further sensitivity analysis has been performed in order to evaluate whether these two variables affect the size or the significance of our trust variable.

Columns three and six show that trust still has a statistically significant negative impact on the level of indebtedness after including the two most important religious groups in Switzerland. Interestingly, religion denomination has an impact on fiscal performance. While we obtain a negative impact of Protestantism on cantonal indebtedness, the share of catholic population on total cantonal population is positively associated with the level of debt. The negative impact of the share of Protestants can be explained using the concept of Protestant ethic, that emphasizes specific values such as the virtues of prudent reinvestment of savings, individual entrepreneurial initiatives, and independence (see Weber 1930, Norris and Inglehart 2004). Such moral values at the individual level seemed to have an impact on states' fiscal discipline, especially in societies based on active political participation rights.

All in all, the significant impact of the trust variable remains unaffected whether we control only for one or for two religious groups, whether we additionally include government centralization or not and whether we additionally control for the share of registered house proprietors or not.

6. Conclusion

This panel analysis within Switzerland provides evidence for the hypothesis that trust in a society influences fiscal performance. The stronger mutual trust is established, the sounder fiscal policy decisions and hence the lower public debts. The results are robust to a number of control variables and the inclusion of additional variables such as government centralization or direct democratic participation rights in Swiss states (cantons). In our case, we use information from direct voter participation on political issues (voter initiatives and public referenda) held in Swiss state governments to measure mutual trust among citizens and between citizens and their representatives. In order to take both aspects of trust into account – trust among members of a society and trust between the incumbent and the constituency – we collected data from all cantonal ballots held between 1981 and 2001 in all 26 Swiss cantons. In total, we analyzed data from 3,100 cantonal ballots that were held in our period of observation. While 75.7 % of the ballots succeeded in the sense of supporting the government proposals, 24.3% failed to support the government. However, since there is a considerable variation in the extent to which Swiss cantons offer possibilities of direct voter participation, the ratio of accepted government proposals would give a biased picture of trust. In order to take the institutional variation into account, we construct our trust measure as the ratio of the ballots that accepted government proposals multiplied with the number of ballots held (acceptance X validation).

These results are consistent with those reported by Putnam (1993) from Italian regions, Keefer and Knack (1997), La Porta et al. (1999) or Zak and Knack (2001) from cross-country regressions or Knack (1999) from US state governments for government performance. The results presented in this paper as well as in previous studies underline the importance of trust as an essential aspect for the well functioning of a government and the institutional architecture in place. However, the understanding of how social capital is built and how government can foster trust remains a fruitful field for further research.

Appendix A

<i>Data description</i>		
<i>Variable name</i>	<i>Description</i>	<i>Source</i>
Trust	Electoral support of government proposals multiplied by number of ballots (support X validation)	Own investigations on the basis of the C2D-Database, Amtsblätter of Obwalden and Appenzell a. Rh. and protocols of town meetings in Glarus, Appenzell i.Rh and Nidwalden.
Debt p. c.	Cantonal debt per capita deflated to the year 1980 in CHF (logarithmized in the estimations)	Swiss Federal Finance Administration
Debt p. GDP	Nominal cantonal debt per nominal GDP	Swiss Federal Finance Administration
Share of registered house proprietors	Share of registered cantonal house proprietors on the cantonal population	Swiss Federal Statistical Office
Share of protestants	Share of protestant population on the total cantonal population	Swiss Federal Statistical Office
Share of catholics	Share of catholic population on the total cantonal population	Swiss Federal Statistical Office
Government Centralization	Share of cantonal public spending on cantonal and local spending	Swiss Federal Finance Administration
GDP	Real cantonal GDP per capita (logarithmized in the estimations)	BAK Basel Economics
Labor Force	Share of employment on the cantonal population	Swiss Federal Statistical Office
Higher Schooling	Share of population with secondary education on the cantonal population	Swiss Federal Statistical Office
Unemployment Rate	Share of unemployment on the cantonal population	Own calculations on the basis of Swiss Federal Statistical Office
Agglomeration	Proportion of local communities having more than 10'000 inhabitants.	Swiss Federal Statistical Office
Population	Cantonal population (logarithmized in the estimations)	Swiss Federal Statistical Office
Population > 65	Share of cantonal population over the age 65 on total cantonal population	Swiss Federal Statistical Office
Population < 15	Share of cantonal population under the age 15 on total cantonal population	Swiss Federal Statistical Office
German Language	Share of German Speaking population	Swiss Federal Statistical Office
