## Abstract

We study the effect of enforcement of labor regulation in Brazil, an economy with a large informal sector and strict labor law. Enforcement affects mainly the degree of compliance with mandated benefits (severance pay; health and safety) in the formal sector; and the registration of informal workers. We find that stricter enforcement leads to higher unemployment but lower income inequality. We also show that, at the top of the formal wage distribution, workers bear the cost of mandated benefits by receiving lower wages. This is not true at the bottom, because of downward wage rigidity. As a result, formal sector jobs at the bottom of the wage distribution become more attractive, inducing the low skilled self-employed to search for formal jobs.

<sup>1</sup> We gratefully acknowledge the suggestions of seminar participants at the World Bank, IFAU, the Stockholm School of Economics, Alicante, the OECD Development Centre, the 2007 IZA/World Bank Conference on Labor Markets, the 2007 EEA Meetings, the 2008 SOLE meetings, Universidade Catolica Portuguesa, especially those of Joe Altonji, Mariano Bosch, Miriam Bruhan, Carlos Corseuil, Per-Anders Edin, Francisco Ferreira, Martin Floden, Richard Freeman, Miguel Gouveia, David Kaplan, Chinhui Juhn, Adriana Kugler, Lars Ljunqvist, Joao Cesar das Neves, Amil Petrin, David Robalino, Stefano Scarpetta, Luis Serven, Rodrigo Soares, and Kathy Terrell. We thank the Brazilian Ministry of Labor for providing the data on enforcement of labor regulation and important information about the process of enforcement, especially Edgar Brandao, Sandra Brandao and Marcelo Campos. We are also very grateful to Adalberto Cardoso for valuable insights on the enforcement of labor regulation in Brazil. Renata Narita provided excellent research assistance in this project. Juliano Assuncao, Joana Naritomi and Rodrigo Soares kindly provided city level data on the quality of institutions. Carneiro gratefully acknowledges the financial support from the Economic and Social Research Council for the ESRC Centre for Microdata Methods and Practice (grant reference RES-589-28-0001), from ESRC grant RES-000-22-2805, and the hospitality of Georgetown University, and the Poverty Unit of the World Bank Research Group. This paper also benefited from financial support from a World Bank research grant. Corresponding author: Rita Almeida, 1818 H Street, NW, Washington DC, 20433. Email: ralmeida@worldbank.org

# 1. Introduction

A large fraction of the labor force in the developing world operates in the informal market. Any study of employment or inequality in these countries needs to distinguish employment and earnings in both the formal and informal sectors. Therefore, it is striking that most empirical analyses of the effects of labor market regulation are either based on a single labor market model, or on the assumption that regulation only affects the formal sector.

In this paper we study the impact of increased enforcement of labor regulation in Brazil, a country where more than 40% of all workers are informal. In Brazil, enforcement is best seen as affecting the provision of mandated benefits in formal jobs (severance pay, health and safety), and the formal registration of informal workers. We focus on the effects of enforcement on the employment and earnings of multiple types of workers, namely formal and informal employees, and self-employed workers. We show that a one standard deviation increase in enforcement is related to: a 6% increase in the share of the population in formal employment; a 6% increase in non-employment; a 10% decrease in informal employment; an 18% reduction in formal wages; a 20% increase in earnings of those who are self-employed; and an overall reduction in inequality. There is little change in the employment and wages of those who are informal employees.

When reading these results it is important to consider a model of the labor market with multiple and interdependent sectors, which is standard in the theoretical literature on labor markets in developing countries. The results in the previous paragraph suggest that even if labor market reform has direct impact only in the formal sector, it will strongly affect workers outside of the formal sector because of linkages across markets. As a consequence of an increase in mandated benefits in the formal sector (making formal sector jobs more attractive), and of an increase in the cost of employing unregistered workers, there is a shift in employment from the informal and self-employment sectors to the formal sector. Formal sector wages decline, because the higher level of mandated benefits passes through to worker salaries in the form of lower wages. Earnings for the self-employed rise, due to a decrease in labor supply to that sector. Wages and employment of informal employees are largely unchanged, which is consistent with the hypothesis that these workers operate in a segmented market, shielded from the rest of the economy. The rise in non-employment may be a consequence of a general increase in

employment costs. However, in the presence of search frictions in the formal sector, it may also result from an increase in the attractiveness of formal jobs, which brings more individuals to search for a job in that sector.

Our study was made possible by our assembly of a new dataset containing labor inspections for each city in Brazil. The main empirical challenge we face comes from the fact that inspections are not likely to be randomly distributed across cities. For example, low compliance with the law is bound to attract more inspections. Similarly, the existence of better institutions in the city could foster better quality in the enforcement of the law, and more compliant individual and firm behavior. In order to minimize these problems, we collect data on two determinants of enforcement: the distance between each city and the nearest regional enforcement office, and the number of labor inspectors in each state. We explore the fact that distance to the nearest enforcement office is likely to be a more binding constraint to the enforcement activity in states where the supply of labor inspectors is smaller. Therefore, in a regression of a labor market outcome on enforcement, we use the interaction between distance and the (log of the) number of inspectors (per firm) in each state to instrument the degree of enforcement in each city, after controlling for polynomials in distance and state fixed effects, as well as a very rich set of city level controls (some of which are also interacted with state level characteristics). In our data, the interaction between distance and the number of inspectors is a strong predictor of enforcement in each city.<sup>2</sup>

Our identifying assumption could be violated if those cities which are far from enforcement offices are also small, rural, and remotely located, and if states with a large number of inspectors engage in active regional policies favoring small and remote cities. Our data does not support these concerns. In particular, we show that the interaction between the number of inspectors in the state and distance from each city to the nearest enforcement office is uncorrelated with the quality of institutions, the quality of the social infrastructure, the amount of state transfers received, the size of the population and its income, the industrial structure, and the levels of past informality, inequality and poverty in each city. It is also likely that the decisions

---

<sup>2</sup> Rajan and Zingales (1998) use a similar procedure to analyze the relationship between financial development and growth, by examining how sectors with different degrees of financial dependence are affected by the degree of financial development in each country. Similarly, there is a large literature studying the effects of trade reforms that compares their effects across sectors with different exposure to foreign competition (Goldberg and Pavnick, 2003).

on regional policy and on the enforcement activity (namely number of inspectors per state) are made by different institutions, and possibly at different administrative levels (state vs. federal).

The paper contributes to a long literature. The theoretical framework on which we draw upon follows Harberger (1962), Harris and Todaro (1970), Fields (1975, 2005), MacDonald and Solow (1985), Bulow and Summers (1986), Acemoglu (2001), Maloney (2004), and Albrecht, Navarro and Vroman (2006).<sup>3</sup> Although labor regulation is strict in Brazil, there is surprisingly large wage and employment flexibility (e.g., Barros and Mendonca, 1996, Barros, Cruz and Mendonca, 1997). The reason for this may be low enforcement. Therefore, when interpreting our findings we think of a model with minimal rigidities, except for frictions in the job search process in the formal sector. More recent contributions to the literature on informality include work by Schneider and Enste (2000), Friedman, Johnson, Kaufmann, and Zoido-Lobaton (2000), Amaral and Quintin (2005), Galiani and Weischelbaum (2007), Boeri and Garibaldi (2006), Loayza, Oviedo and Serven (2005), de Paula and Scheinkman (2006), Bosch, Goni and Maloney (2007), and World Bank (2007). Especially related to us is the study of inequality in economies with dual labor markets, such as Fields (1979, 2005), or Bourguignon (1990).

Modern surveys of the role of labor market institutions include Layard and Nickell (1999), or Kugler (2007), among many others. The increasing availability of micro data lead to the emergence of several studies examining the effect of labor market regulations in developing countries, such as Kugler (1999, 2001, 2004), Kugler and Kugler (2003), Eslava, Haltiwanger, Kugler and Kugler (2006), Ahsan and Pages (2007), Petrin and Sivadasan (2006), or the studies in Heckman and Pages (2004). Two papers are especially close to ours. Besley and Burgess (2004) explore within country (district level) and across time variation in labor reforms in India to study the effect of labor regulations on productivity, investment, employment and poverty. We explore a very different source of institutional variation, and use labor market data disaggregated at the city level. Marrufo (2003) examines the consequences of the reform of social security in Mexico, using a Harberger model with two employment sectors and worker heterogeneity. This paper is one of the few that considers labor market policy in a multi-sector labor market.

Finally, we relate to the large literature on the labor market effects of mandated benefits (Summers, 1989, Lazear, 1990), both in the U.S. (e.g., Gruber, 1994) and in developing countries

---

<sup>3</sup> Several papers try to empirically distinguish different models of the labor market (segmented and non-segmented). See e.g., Dickens and Lang (1985), Heckman and Hotz (1986), Maloney (1999), Filho, Mendes and Almeida (2004), Navarro-Lozano and Schrimpf (2004), Bosch and Maloney (2006), Almeida and Bourguignon (2006).

(e.g., Gruber, 1994, 1997, Kugler, 2005, MacIssac and Rama, 1997). Relatively to the literature, our model allows the informal sector to respond to changes in mandated benefits.

This paper proceeds as follows. In the next section we provide background information on the Brazilian labor market, its institutions, and the structure of the enforcement process. Section 3 presents the simple theoretical framework that guides our work. Section 4 describes the data. Section 5 explains the empirical strategy. Section 6 shows the empirical results, and discusses the main lessons for labor markets in developing countries. Section 7 concludes.

## **2. Labor Market Regulation and Enforcement in Brazil**

### **2.1 Labor Regulations**

At least on paper, Brazil has one of the least flexible labor market regulations in the world. The law establishes that all employees must have a work permit where the employment history of the worker is registered (*carteira de trabalho*). This permit entitles the worker to several benefits, such as a retirement pension, unemployment insurance, and severance payments. The labor code is largely written into the Brazilian constitution, which makes any amendments very difficult. The constitution of 1988 introduced several changes to the labor code which increased the degree of worker's protection (see e.g., Barros and Corseuil, 2001). For example, the law establishes that the maximum work period is of 44 hours a week, the maximum period for continuous shift work is 6 hours, minimum overtime pay is 1.5 times the normal hourly wage, paid leave is at least 4/3 of the normal wage, paid maternity leave is 120 days, and the employer must contribute monthly to social security and to a job security fund, the FGTS. This a fund administered by the government, employers and employees, which accumulates while the worker is employed by the firm. The employer must contribute monthly with 8% of the employee's current wage to the fund (10% from 2001 onwards).<sup>4</sup> Adding up all the costs, in order for a worker to receive a net wage of Reais 100, the firm needs to disburse approximately Reais \$165,7 (Cardoso and Lage, 2004).

Firing a worker in Brazil is not significantly more difficult than firing a worker in other Latin American countries, although it is definitely more costly. Employers must give advance

---

<sup>4</sup> As a consequence the accumulated FGTS of a worker in a given firm is proportional to its tenure. Only workers that are dismissed for an unfair reason or those that are retired have access to this fund. Workers can also use their FGTS in exceptional circumstances like when buying a house or paying large health expenses. Upon dismissal, workers have access to the entire fund, including all the funds accumulated in previous jobs, plus a penalty in proportion to the fund accumulated during the tenure in the last firm.

notice to workers and, in the interim period, workers are granted two hours a day to search for a job. This period is never smaller than one month and recently it became proportional to the worker's tenure. During this period, employers cannot adjust the worker's wage. This implies that approximately 25% of the paid hours (2 out of 8 possible hours in each working day) are not worked. Due to a drop in motivation, the productivity of a dismissed worker also falls once he is given notice of dismissal so the overall decline to production is likely to be above 25% (Barros and Corseuil, 2001, argue that the fall in production is near 100%). Workers who are dismissed at will have the right to receive compensation paid by the employer, over and above what was accumulated in the worker's job security fund (FGTS). In particular, the law establishes that a penalty equal to 40% of the fund accumulated during the worker's tenure with the firm is due to the worker.<sup>5</sup> Therefore, dismissal costs increase with the duration of the work contract. One obvious perverse effect of such high severance pay is that several workers force their dismissal, potentially increasing turnover rates, and increasing the firm's costs (see, e.g., Neri, 2002).

There is one final aspect that should be emphasized: severance payments received by the worker are not subject to income taxation (this is not true in most countries). This means that workers value one Real of FGTS more highly than one Real in gross salary. Moreover, firms pay taxes on profits which can add up to more than 30%. As a result the cost of FGTS to the firm is much smaller than the value of FGTS to the worker.

## **2.2. Enforcement of Labor Regulations**

Firms weight the costs and benefits of complying with the strict labor regulation. They may decide to hire informally, or to hire formal workers without complying fully with specific features of the labor code (e.g., avoid the provision of mandatory health and security conditions, or avoid payments to social security). The expected cost of evading the law is a function of the probability of being caught and of the monetary value of the penalties (fines and loss of reputation). In turn, the probability of being caught depends on firm characteristics (such as size and legal status)<sup>6</sup> and on the degree of enforcement of regulation in the city where the firm is located. Compliance with labor regulation in Brazil is enforced by the Ministry of Labor. Given

---

<sup>5</sup> This charge was elevated to 50% after 2001 (outside our period of analysis), with the additional 10% going directly to the government. For a period after 2001, the FGTS contribution was also raised from 8 to 8.5%.

<sup>6</sup> Cardoso and Lage (2007) argue that the integration of firms in international trade and the need to comply with international quality standards (e.g., ISO certificate) implicitly forces firms to comply with regulation. For example, it is often the case that firms who which to export need to prove their compliance with labor regulations and cannot resort to any forms of child labor or slavery.

the size of the country, enforcement is first decentralized at the state level (the state level labor office is called *delegacia*) and then at a local level, the subregion (the local labor office is called *subdelegacia*). A *subdelegacia* is located in a city, but its catchment area generally includes more than one city (or *município*). In each state, the *delegacia* is always located in the state capital and the number of *subdelegacias* within the state is a function of the size and economic importance of each region. For example, the state of Sao Paulo has 21 *subdelegacias* while other smaller states, like Acre or Amapa, only have one *subdelegacia*, which coincides with the *delegacia*.

Labor inspections were probably of little relevance during the 70's and 80's. In the late 80's the Brazilian economy had several hyperinflation episodes and this contributed to a significant depreciation of the nominal value of fines. However, during second half of the 90's labor inspections gained importance. Several reasons are behind this. On one end, labor regulation became stricter after the 1988 Constitution. On the other end, the strong government deficit in the mid 1990s lead the government to search for alternative ways to collect revenue, and labor inspectors started being used as tax collectors. Their main goal was to collect job security contributions which helped reduce the size of the government deficit, at least in an accounting sense (since they cannot be used directly by the government to fund its expenditure). It was probably only after this change that labor inspections gained prominence.

Inspectors are affiliated with a specific *subdelegacia* but, to deter corruption, they must periodically rotate across *subdelegacias*. The maximum period an inspector can stay in one *subdelegacia* is twelve months (Cardoso and Lage, 2007). In theory, an inspection can be triggered either by a random firm audit, or by a report (often anonymous) of non-compliance with the law. Reports can be made by workers, unions, the public prosecutor's office, or even the police. In practice, since the number of labor inspectors is low relatively to the number of non-compliance reports, most inspections are triggered by these anonymous reports. Inspectors assess the compliance of each inspected firm with several dimensions of labor law (e.g., worker's formal registration, severance pay, minimum wage regulation, hours of work). Almost all of the targeted firms are formal firms because it is difficult to visit a firm which is not registered, since there are no records of its activity. As a result, an enormous fraction of informal employment is left out of the inspectors' reach. Inspectors have a performance based pay scheme. In particular, up to 45% of their wage is tied to the efficiency of the overall enforcement system (1/3 is tied to the inspectors own performance while 2/3 is tied to the system's global performance). Their base

salary is also fairly competitive. In 2004, their monthly wage was between USD 2,490 (starting position) and USD 3,289 (top management).

When faced with violations of the labor code, inspectors must immediately notify the firm. The firm then has 10 days to present evidence in its defense. After that period, the process is re-examined by a different inspector from the one issuing the fine, who deliberates about its fairness, and the result is reported to the head of the *subdelegacia* (*subdelegado*). If firms do not contest the fine and pay it within 10 days of their notification, there is a 50% discount on the amount of the fine. Alternatively, if firms file an appeal, they must deposit the total value of the penalty until a second decision has been reached. In practice, small and medium firms pay the fines early to take advantage of the discount. Larger firms, with their own legal departments, tend to refute the deliberations, and often avoid the payment of any fines. Fines can be either fixed, or indexed to firm size and profitability. For example, a firm is fined by Reais 446 for each worker that is found unregistered during an inspection. Depending on its size and profitability, if a firm does not comply with the mandatory contributions to the FGTS, then it can be fined an amount between Reais 16 and Reais 160 per employee.<sup>7</sup>

Although the number of inspectors was relatively low in the early 2000s when compared with a decade before, inspectors were able to reach a significant part of the total labor force in formal firms in Brazil. In 2002, 304,000 firms were visited by labor inspectors, reaching more than 19,000,000 workers (Cardoso and Lage, 2007). Of these, approximately 17% of the firms received a notification of non-compliance with the law, but less than 3% of the workers were registered, a small number given that 50% of employment is informal in Brazil. This could reflect the fact that informal workers are concentrated in small and informal firms outside the reach of labor inspectors, but it may also suggest that, among the different types of labor violations,<sup>8</sup> formalization is not the sole (or even the main) target of the inspections. According to Cardoso and Lage (2007), the main target for labor inspectors is the lack of payment of the job security fund and compliance with health and safety conditions on the job. The evidence in table

---

<sup>7</sup> Cardoso and Lage (2007) argue that the magnitude of the fines is quite reasonable to work as a deterrent to crime, and that the main problem is their enforcement.

<sup>8</sup> All violations are punishable with fines. Inspectors issue fines for the non-registration of workers, disobedience of the official work period or hours worked, non-compliance with the mandatory wage payments (including minimum wages), missing FGTS contributions or health and safety violations. It is useful to note that fines may be inaccurate measures of enforcement for two reasons. First, we only see a fine if a violation is detected, and much enforcement may have a deterrent effect not translated into fines. Second, inspectors avoid issuing fines, and try to first negotiate with the firm non-litigious ways to solve the illegality they observe (Cardoso and Lage, 2007).

A1 also supports this. When looking at different types of fines issued by inspectors in 2002 three categories comprise 75% of the total number of fines: registration, FGTS, and *other* types of violation (including health and security violations). .

The Ministry of Labor makes an effort to apply homogeneous criteria for enforcing labor regulation throughout the country (e.g., by providing training and using similar software) but, in practice, this is very difficult to achieve because the country covers a very large and diverse geographical area. Inspectors are also probably very heterogeneous. Moreover, they have to travel different distances and face varying workloads depending on where they are located. This will give rise to substantial regional variation in the degree of enforcement across cities, which we explore econometrically.

### **3. Theoretical Background**

In interpreting our findings we consider a multi-sector model of the labor market. We do not develop a full model since there is a rich literature we can draw on, namely Lewis (1954), Harberger (1962), Harris and Todaro (1970), Fields (1975), MacDonald and Solow (1985), Bulow and Summers (1986), Acemoglu (2001), Maloney (2004), Albrecht, Navarro and Vroman (2006), Bosch (2007). Suppose that there is a formal sector, an informal sector, and unemployment. In the formal sector the wage is higher, but there is risk of unemployment because of (search) frictions. In the informal sector there is no unemployment, so the wage is lower. Workers are free to choose in which sector to operate. On the labor demand side, firms decide to hire either formally or informally. The cost of hiring formal workers is their wage, in addition to payroll taxes and mandated benefits. The cost of hiring informal workers is their wage plus the potential penalty the firm has to pay if caught hiring this type of workers.

Our empirical work supports two small additions to this simple framework. First, following some authors we introduce duality within the informal sector (e.g., Fields, 1990, 2005, Maloney, 2004). While it is true that there is a group of informal workers who could be working in the formal sector if that was their choice, there is another group which operates in a segmented labor market, queuing for a formal sector job (as in the more traditional view of the informal sector; e.g., Dickens and Lang, 1985).<sup>9</sup> Second, in the absence of asymmetric information

---

<sup>9</sup> In the empirical work we will not be able to rigorously distinguish between upper and lower tier informal workers. However, there is a suggestion in the literature that informal wage earners belong in the lower tier, while part of

between workers and firms, wage rigidity, or credit constraints, mandated benefits (such as severance pay, or health and safety on the job) are borne by workers in the form of lower wages, and have no effects on employment. While these assumptions may hold at the top of the wage distribution, they are unlikely to be true at the bottom, which will lead us to see some effects of mandated benefits on employment (e.g., Summers, 1989, Mitchell, 1990, Lazear, 1990).

What are the consequences of an increase in enforcement in this simple model? We start by assuming that enforcement focuses only on the compliance with mandated benefits in the formal sector. One simple way to model this is to assume full compliance with mandated benefits in the formal sector, and to equate an increase in enforcement with an increase in the size of amount of the mandates. In this case, we expect a contraction in the labor demand curve because formal workers become more expensive. We also expect an expansion of the formal labor supply curve, since formal jobs become more attractive. If the cost of mandated benefits to the firm was equal to their value to the worker, and if there were no wage rigidities, then the equilibrium wage in the formal sector would decrease by an amount equal to the cost of the mandated benefits, with no change in formal employment (Lazear, 1990), and no change in the informal sector. This case is depicted in figure 1 which plots demand and supply to the formal ( $D_F$  and  $S_F$ ) and informal sectors ( $D_I$  and  $S_I$ ), in an economy with and without enforcement (e.g.,  $S_F^E$  vs.  $S_F^{NE}$ ).

Several empirical papers estimate the extent to which payroll taxes and mandated benefits translate into lower wages to be quite large (e.g., Gruber, 1994, 1997, Marrufo, 2001, Kugler, 2005, Heckman and Pages, 2003).<sup>10</sup> At the bottom of the wage distribution, it is likely that the pass-through rate is below 100%, because downward wage rigidity is limited. At the top of the wage distribution, it is possible that it is close to 100% (or even higher), especially for job severance pay since workers can easily gain access to the job severance fund. Furthermore, it could be above 100% if: i) firms pay taxes on profits but workers do not pay taxes on severance payments (this is the case in Brazil), which means that for each Real the worker receives as severance pay (net of taxes) the firm needs to disburse less than one Real; ii) the costs of

---

self-employed workers are likely to be in the upper tier (e.g., Bosch and Maloney, 2006). Table A3 in the appendix gives mixed evidence on this. While the assumption that the self-employed are at the upper tier of the informal sector looks reasonable for those at the top of their wage distribution, it does not for those at the bottom, who earn even less than the poorest informal wage earners. These are probably street merchants or individuals in similar occupations.

<sup>10</sup> Heckman and Pages (2003) estimate rates of pass-through close to 90% in OECD countries, while Marrufo (2001) and Kugler (2005) have estimates closer to 60-80% for Mexico and Colombia. Gruber (1994, 1997) stands out for estimating 100% pass-through rates, for the US (maternity benefits) and Chile (payroll taxes).

providing better health and safety conditions on the job are below the value workers place on them. This case is shown in figure 2 where, for simplicity, we assume there is no change in the demand for informal labor. In principle, the equilibrium demand curve for informal labor in an economy with enforcement will be above the original curve, since the equilibrium formal wage is below the original wage.

If pass-through rates are either above or below 100%, then labor supply in the informal sector will be affected. Low wage jobs in the formal sector become more attractive if wages do not adjust to an increase in mandated benefits: informal workers may be willing to leave their jobs to search for a new job in the formal sector, even if they risk of unemployment. If the risk of unemployment increases substantially (because of a contraction in labor demand due to higher labor costs), then informal employment could rise: those searching for work in the formal sector could decide to take up employment in the informal sector. High wage jobs in the formal sector may become more or less attractive to informal workers depending on their valuation of the new mandated benefits, and the rates of pass-through to wages. Finally, in this scenario, wages are likely to decline in the formal sector. Wages in the informal sector may increase or decrease depending on whether there is an expansion or contraction in the labor supply.

Suppose now that enforcement affects only worker registration. Firms are urged to reclassify their informal workers as formal (under the penalty of being fined), and then comply with social security, payroll, or severance payments. In this case, an increase in enforcement translates into an increase in the cost of hiring informally, and a contraction in the demand for informal workers. The result would be a shift in employment from the informal to the formal sector, and a decline in wages in both sectors. This is shown in figure 3 in a very simplistic way, since we do not allow the full equilibrium effects to take place in the figure (we keep the demand for formal workers and supply of informal workers fixed).

In this simple competitive model, enforcement is always distortionary and welfare reducing. More generally, the welfare implications of increases in enforcement are mixed. The standard view is that taxes and mandates impose distortions and reduce welfare. However, if formal jobs are intrinsically more productive than informal jobs, there may be a role for promotion of formality (Acemoglu, 2001), as long as it does not involve pure reclassification of

workers doing the same job. Similarly, if workers are credit constrained, mandated benefits such as severance payments may be welfare enhancing (Alvarez and Veracierto, 2001).<sup>11</sup>

## 4. Data

The paper explores several sources of data. First, we use administrative data on the enforcement of labor regulations (in 2002), collected by the Department of Inspections at the Ministry of Labor for our project. This data contains information on the number and location of regional labor offices, number of inspected firms, number of fines issued in each city, and number of inspectors per state. Our measure of enforcement is the log number of inspections in each city (plus one) minus the log of the number of firms in the city (log inspections per firm in the city).

Second, we compute several city level labor market indicators using the 10% sample of the Brazilian population census in 2000, containing detailed information on labor market outcomes for 15 million individuals. In particular, we compute the share of workers who are registered, unregistered, or self-employed, the share of non-nemployed, average wages for each type of worker, and measures of income and wage inequality in the city (including several percentiles of the income and wage distributions, and the city 90-10 income and wage ratio). We also compute similar statistics for individuals in different gender, age and education groups. Table A2 reports the proportion of the adult population in each employment category.<sup>12</sup> Registered and unregistered wage earners, self-employed, and non-employed individuals, together account for 87% of the adult population.<sup>13</sup> Therefore, in the empirical work we focus on these four groups. Informal employment and self-employment are considered two separate categories, as emphasized in the recent literature (Maloney, 2004, Fields, 1990, 2005). Finally, we have also computed some measures of past informality, poverty and inequality in the city

---

<sup>11</sup> Several authors consider non-competitive models of the labor market, in which firms have some sort of monopsony power. In these models mandated benefits can increase the bargaining power of workers, allowing them to increase their total compensation package (e.g., Saint-Paul, 1995, Ljunqvist, 2002). As a response, there can be an increase in the wage of informal workers to keep them indifferent across sectors.

<sup>12</sup> In the 2000 Census, each individual is classified into one of the following 10 categories: registered domestic worker, unregistered domestic workers, registered wage earner, unregistered wage earner, employer, self-employed, unpaid apprentice, unpaid employee (usually in family business), working for self-consumption, and without status (or not employed).

<sup>13</sup> The remaining 13% are formal and informal domestic employees (0.8% and 2.5% respectively), employers (1.5%), interns or apprentices (0.1%), unpaid employees (3.5%), and individuals working only for self-consumption (4.6%). These individuals are excluded from our analysis. These are small groups of the population and unlikely to be too much affected by changes in enforcement.

using the 1980 Brazilian census.<sup>14</sup> All city level variables are computed using population weights. In 2002, there are 5,513 cities in Brazil.

Third, we use detailed information on other city level characteristics from two statistical and research institutes in Brazil - *Instituto de Pesquisa Economica Aplicada* (IPEA), and *Instituto Brasileiro de Geografia e Estatistica* (IBGE).<sup>15</sup> In particular, we collect information on the city's GDP per capita (2000), total number of firms (2000), average firm size (2000), share of agriculture in GDP (2000), share of manufacturing in GDP (2000), share of services in GDP (2000), geographical city characteristics (including geographical area, altitude, longitude and latitude), city transportation costs (1995), total federal transfers to each city (1990), the city head count poverty index and the city Theil inequality index. The total number of firms (2002) in each city comes from the *Cadastro Central de Empresas*, collected by IBGE, which only includes formal firms. We also use past city level variables published by IPEA for the years 1970, 1980, and 1991, including city population, per capita income, average years of schooling and share of population in urban areas. Because some of the cities in 2000 did not exist in the 70's, 80's or even 1991, we use the more aggregate definition of minimum comparable unit (MCU), published by the IPEA, to obtain an estimate of these city variables in previous years.<sup>16</sup> For all cities in a given year, we know to which MCU each city was previously mapped into. Then, we computed the average value of each variable for each MCU (weighted by population size in each city), and assigned it to each city in the MCU.

Fourth, we use information on the institutional development of the city, published by IBGE, used in Naritomi, Soares and Assuncao (2007), and kindly provided by the authors. These measures include an index of the access to justice in the city, an index of managerial capacity in the city and an index of political concentration in the city (based on a Hirshman-Herfindhal index of the shares of the political parties). The index of managerial capacity in the city measures the quality of local administration, and is used by the Ministry of Planning to monitor the administrative performance of cities. Access to justice measures the penetration of the rule of

---

<sup>14</sup> In the 1980 Census there is no information on the whether the worker has an official work permit. Instead, the survey collects information on whether the worker makes social security contributions. Hence, in 1980 the definition of informal worker differs from the one used in 2000. In 1980 a worker is considered informal if he/she do not make any social security contributions. We expect the two definitions to be correlated, since almost no unregistered workers pay social security contributions.

<sup>15</sup> These statistics are publicaly available at <http://www.ipeadata.gov.br> and <http://www.sidra.ibge.gov.br/>.

<sup>16</sup> In 1970 and 1980 there existed 71% and 72% of the cities that existed in 2000, while in 1991 there existed 82% of the cities in 2000. A MCU is an area (set of cities) which is defined in such a way that can be compared over time.

law, in particular the existence of courts or justice commissions in the city. We also consider state aggregates of these variables, by averaging across cities.

Fifth, we compute the distance and travel time (by car) between each city and the nearest *subdelegacia* in the state. The transportation of inspectors from the *subdelegacia* to each firm is made using ground transportation, usually car. Hence, the enforcement of labor regulation will be easier and less costly the closer a *subdelegacia* is from the city where the firm is located. We construct a measure of the accessibility of inspectors to firms by using the travel time from each city to the nearest *subdelegacia* within the state (minimum distance). Data on travel times and travel distances between any two Brazilian cities is available from one of the largest Brazilian auto insurance companies (BB), which collects very detailed information on distances across cities.<sup>17</sup> When firms are located in cities that have a *subdelegacia* the measure assumes the value zero. We also construct the distance between each city and the capital city within the state. In the remaining of the paper we focus on travel time as the most relevant measure of distance. A third measure of the remoteness of the city, or of its access to markets, is an index of transportation costs between each city and the nearest capital city taken from IPEA (1995). Sample statistics for the main variables we use are presented in table 1.

## 5. Empirical Strategy

Our main empirical specification is the following:

$$Y_{ij} = \alpha + \beta E_{ij} + \delta X_{ij} + \eta_j + u_{ij} \quad (1)$$

where  $Y_{ij}$  is the outcome of interest in city  $i$  and state  $j$ ,  $E_{ij}$  is enforcement in city  $i$  and state  $j$ ,  $X_{ij}$  is a vector of city level controls,  $\eta_j$  is a state fixed effect, and  $u_{ij}$  is the residual.  $\beta$  is the parameter of interest and measures the impact of enforcement on labor market outcomes. The main outcomes we consider are the share of informal workers in the city, poverty, inequality and unemployment, and earnings and employment of formal, informal, and self-employed workers. Enforcement is measured with the logarithm of the number of inspections per firm in the city (computed as the number of visits by labor inspectors plus one, divided by the number of firms).

---

<sup>17</sup> This information is available online at [www.bbseguroauto.com.br](http://www.bbseguroauto.com.br). When collecting information on distances. We have faced two obstacles First, could not find information online for those cities that have only recently been recognized as cities. In these cases, we have located the closest nearby city (using maps) and used that information instead. Second, most on the cities in Amazonas use the maritime rather than the ground transportation both for goods or persons. Hence, the travel distance by car is meaningless for this state and, hence, we have excluded it from the analysis.

Estimating equation (1) using ordinary least squares would produce biased estimates of  $\beta$  since  $E_{ij}$  is potentially correlated with  $u_{ij}$ . Two main reasons are behind this. First, enforcement may be stricter in cities where violations of labor law are more prevalent. This could happen because inspections are triggered mainly through reports of illegal activity. Second, enforcement may be stricter in cities where institutions are better developed. In order to overcome this problem, we collect data on two determinants of enforcement: the distance between each city and the nearest regional enforcement office, and the number of labor inspectors in each state. Then we explore the fact that distance to enforcement centers is likely to have different effects on enforcement depending on the available number of inspectors. In particular, distance will be a greater constraint to the enforcement activity in cities where the supply of labor inspectors is smaller, and therefore it should have a disproportionately large effect on enforcement (and labor market outcomes) in states where the number of inspectors is low.

We use the interaction between distance and the number of inspectors (per firm) in each state as an instrument for the degree of enforcement in each city, while controlling for distance and state fixed effects, in addition to a very rich set of city level controls (some of which are also interacted with state level characteristics, as explained in the next paragraph). State fixed effects account for the fact that states with different numbers of inspectors per firm may also be different in other dimensions, while distance to the nearest enforcement office accounts for the non-random location of enforcement offices. Any remaining variation is given by the differential effect of distance across states with varying numbers of inspectors.<sup>18</sup>

We include as additional controls several city level characteristics: income per capita, population size, average schooling, and share of the population living in urban areas in 1970, 1980 and 1991, city latitude, longitude, altitude and area, and two measures of institutional development in the city, taken from Naritomi, Soares and Assuncao (2007). Finally, one could be concerned that the number of state level labor inspectors is simply correlated with other state level characteristics, like its level of development or institutional quality which interacted with distance could also affect the city level outcomes of interest. Therefore we include in the reduced

---

<sup>18</sup> A similar identification procedure is used by Rajan and Zingales (1998) who examine the effect of financial dependence on growth, or Goldberg and Pavnick (2003), who study the effect of trade reform on informality. Several difference-in-difference strategies (and other grouping estimators) account for location and time effects and implicitly instrument the variable of interest with the omitted interaction between location and time (e.g., see Meghir and Whitehouse, 1995).

form equation the interaction between distance to the enforcement office and other state characteristics: the log of the average of per capita GDP in the state between 1970 and 2000, and measures of city level institutions averaged at the state level (access to justice, governance and political concentration). Other controls are distance to the state capital and log of transportation costs to the nearest capital interacted with the four variables above, and with the log of the number of inspectors per firm in the state.

Figures 4 and 5 show the intuition of our procedure. Figure 4A corresponds to the first stage of our IV strategy. For each state, we run a regression of the degree of enforcement (measured by the log of number of inspections per firm in the city) on distance to the nearest enforcement office (measured in hours of travel by car). Each circle represents a coefficient of one of these regressions, which is plotted against the log number of inspectors per firm in the state. The size of the circle is the inverse of the standard error of the estimated coefficient. As expected, all coefficients are negative, indicating that cities located away from enforcement offices have low levels of enforcement. More importantly, the figure shows that these coefficients are disproportionately more negative in states with lower endowments of inspectors. The slope of the regression line is positive and significant, as reported in the note of the figure.

If this is the case, we would expect the relationship between distance and the labor market variables of interest, such as unemployment or informality, to be more pronounced in states with low numbers of inspectors. We show that this is true in figures 4B and 4C respectively, which correspond to the reduced form regressions of the outcome of interest on the instrument. Again, the slopes of the regression lines are statistically different from zero, as reported in the note of the figure. In drawing Figure 4B, we started by regressing, for each state, the share of informal workers in each city in 2000 on the distance to the nearest enforcement office. Then we regress the estimated coefficient for each state on the log number of inspectors per firm in the state. For Figure 4C we do the same but we use the unemployment rate in the city in 2000 as the outcome of interest, instead of looking at the share of informal workers. All regressions are weighted by the inverse of the estimated variance of the coefficient.

Figure 5 corresponds to two checks on the validity of our IV procedure. This procedure is valid if the effect of distance on labor market outcomes does not vary across states (except through its effect on enforcement), or if this variation is not correlated with the number of state inspectors. This assumption may not hold if, for example, those cities which are far from

enforcement offices are also small, rural, and remotely located, and if states with a large number of inspectors engage in active regional policies favoring small and remote cities. However, decisions about regional policy and about the number of inspectors per state are probably done by different institutions, and even at different administrative levels (state vs. federal). Moreover, for reasons discussed above, it is unlikely that inspections were important for labor market outcomes before the 90s. Hence, we do not expect the relationship between distance and city level variables measured in 1980, such as the share of informal workers, or GDP per capita, to vary systematically with the number of inspectors in the state. Figures 5A and 5B document that this is indeed the case (we cannot reject that the slopes of the regression lines are equal to zero).

Table 2 provides formal evidence that the interaction between the number of inspectors in the state and distance from each city to the nearest enforcement office is uncorrelated with several city level variables proxying institutional quality or different dimensions of regional policy. One way to think about confounding interactions between other state characteristics and distance to large city centers on one side, and our instrument on the other, is to consider the role of state level policies to reduce regional inequality (associated with distance to large cities). One possibility is road construction, but since we measure distance to the nearest *subdelegacia* of the Ministry of Labor in travel time by car (not in miles), the quality of the road infrastructure is already accounted for. Since the transportation of goods in Brazil is done almost exclusively by train, we investigate whether the interaction of distance and state inspectors per firm affected the likelihood of each city to have a train station. The coefficient is negative but statistically insignificant. Second, we checked whether enforcement could be capturing variation in the quality of other city institutions. If states with more inspectors per firm tried to minimize the impact of distance to focal cities on the access to institutions, this correlation would be present even after we instrument labor inspections. We proxy city level institutional quality using three indices: access to justice, governance, and political concentration. The empirical findings do not show evidence that this is a significant source of concern.

Third, we look at city level inequality in social infrastructure, measured by the log number of households with access to piped water, sanitation, and electricity (normalized by the number of individuals in the city). We find no correlation between the instrument and access to water and sanitation. There is a small correlation with access to electricity, but it has the opposite sign to what one would expect if it were capturing confounding variation in other state policies.

Moreover, looking directly at the log of current transfers from states to cities (drawn from state tax revenues) per capita, we find no strong correlation between our instrument and this variable.

Fourth, we assessed whether the instrument is correlated with the enforcement of other types of law, by looking at the number of homicides per 100,000 individuals in the city, and again we found no statistically significant effects.

Fifth, the level of development of the state may itself be inequality reducing and could be correlated with the number of available inspectors per state. For example, in more developed states the quality of (private) transportation may be better so that roads are less of an obstacle, and goods and information may flow easily across cities (even if they are remote). This may affect the way economic activities are distributed across cities. The first thing to notice is that the instrument is not correlated with either city size (measured by log population) or log GDP per capita. More interestingly, when we use as the dependent variable the shares of GDP attributed to agriculture, industry and services, these are also not correlated with our instrumental variable. Therefore, the basic structure of economic activities in the city is not substantially affected by the variable we use to instrument enforcement, although (as we will show in the next section) the structure of the labor market will see some changes.

Finally, we show that the instrument cannot predict past values of the main variables of interest in this paper: city level informality (the share of workers not paying social security), the unemployment rate, inequality (theil index), and the poverty rate measured in 1980. In sum, this table shows that the instrument is both theoretically plausible and empirically credible.<sup>19</sup>

Table 3 reports estimates for the coefficient on the instrument, and the average marginal effect of distance on enforcement. The relevant F-statistic measuring the strength of the first stage relationship is shown at the bottom of each column. Since we are using a large set of controls, for transparency we report three different specifications. In the first column we regress enforcement (measured by the log number of inspections per firm in the city) on distance to the nearest labor office (measured in travel time), its interaction with the number of labor inspectors per firm in the state (the instrument), and state fixed effects. In the second column we add distance to the state capital and its interaction with state inspectors per firm. In the third column

---

<sup>19</sup> One could think that the interaction term we emphasize is hard to identify in small samples, and that the findings in table 2 are solely due to imprecision. This is not the case. In appendix table A4 we show not only the coefficient on the interaction of distance and state inspectors, but also the coefficients on the interactions between distance and all the other state level variables, which we use as control variables in table 2. The only interaction term that is systematically unrelated with the dependent variables in table 2 is the one we use as an instrument for enforcement.

we present the full specification. Across columns, the marginal effect of distance on enforcement is negative, and the coefficient on the interaction of distance and inspectors in the state is positive, showing that the effect of distance is smaller in states with more inspectors. The coefficient on this interaction is similar across columns, and the F-statistic is always high so there is no concern with the instrument being weak (Stock and Yogo, 2003).

## 6. Empirical Findings

### 6.1 Aggregate Labor Market Outcomes

Table 4 reports least squares (panel A) and instrumental variables (panel B) estimates of the effect of log inspections per firm in the city on the share of informal workers (defined as those without a work permit and the self-employed), the head count poverty ratio, the unemployment rate, and the Theil inequality index in the city. The controls and instruments were described in detail in the previous section and are also described at the base of the table. The instrumental variable estimates shows that a one unit increase in the log of inspections per firm in the city (corresponding to a 1 standard deviation, or sd, increase) leads to a 15 percentage point (or pp), reduction in the proportion of informal workers in the city (corresponding to 1 sd of that variable), a 9 pp (1.5 sd) increase in the unemployment rate, a 0.12 pp (1 sd) reduction in the Theil inequality index, and a 5 pp (0.25 sd) reduction in the poverty rate.

The IV estimates are larger in absolute value than the OLS estimates.<sup>20</sup> This suggests that cities with more crime also have stricter enforcement, which could happen because inspection activities respond to reports, and these are more common in places with more violations of the law. Table A5 (in the appendix) shows that the findings in table 4 are robust to the inclusion of city sectoral composition, average firm size in the city, and additional worker variables as controls, two variables which may be correlated with the structure of the labor market in the city.

In line with the findings in Heckman and Pages (2004), our results show that strict regulation increases unemployment. Theoretically this can happen either because firms are more

---

<sup>20</sup> It is not surprising that OLS estimates of equation (1) are biased, because inspections are triggered through (anonymous) reports of violations of the law. Furthermore, we can also show that enforcement is strongly related with almost all institutional variables in Table 2. Therefore, IV will be different from OLS. It is also possible that the effect of enforcement varies across cities, in which case the IV estimate is a weighted average of effects (e.g., Imbens and Angrist, 1994, Carneiro, Heckman and Vytlačil, 2006). Indeed, if we include in the model an interaction of enforcement with, for example, the share of informal workers in the city in 1980, we find that the effect of enforcement declines with the level of past informality in the city (result available on request from the authors).

constrained or because more individuals start searching in the formal sector. On the other end, as emphasized by Freeman (2007), enforcement is also associated with a strong reduction in income inequality. Notice that the effect on the poverty rate is fairly small.

## **6.2 Wages and the Distribution of Employment across the Formal and Informal Sectors**

While the results we just reported are interesting, a more detailed analysis of the labor market is needed to understand the mechanisms behind them. This section investigates the effect of enforcement on the quantities and prices in each sector of the labor market. In particular, we examine movements in the proportion of workers who are formal, informal, or self-employed, and in the distribution of wages for each of these groups.

Table 5 reports the effect of enforcement on the share of the adult population in the city in each employment category, in 2000. In cities with stricter enforcement there is more formal employment, more non-employment, and less self-employment. There is no statistically significant effect of enforcement on the number of informal wage earners. If workers shift sectors in response to changes in enforcement, then the composition of workers in each sector is bound to be affected as well. In table 6 we estimate the effect of enforcement on the distribution of schooling for each type of workers. Each column refers to a different quantile of the schooling distribution, which is used as the dependent variable in the regressions. The table shows a statistically significant decrease in the education of formal workers, and a statistically significant increase in the education of self-employed individuals. This suggests that those individuals leaving the self-employment sector to join the formal sector come from the bottom of the distribution of schooling in both sectors.

As argued in section 3, mandated benefits will have differential effects across the wage distribution. Therefore, we study different percentiles of the wage distribution, as opposed to focusing only on the mean. Table 7 documents the effect of enforcement on wages. The top two panels correspond to the OLS and IV regressions we have been presenting so far in the paper. However, in light of the results of table 6, we present a third panel where we also control for the education of workers in each sector. For each quantile of the distribution of wages in the sector, we control for the corresponding quantile of the distribution of schooling in the same sector. Although it is unlikely that schooling is an exogenous variable in these regressions, we hope that this procedure allows to distinguishing true changes in wages from changes in the composition of

workers. The findings show that an increase in enforcement is associated with a decline in wages at the top of the formal wage distribution, and an increase in wages among the self employed (with no statistically strong effect on the distribution of wages for informal wage earners). As a result, there is a fall in the differential between the wages of formal and informal workers (although this result is not shown directly, it is available on request). These effects remain strong, though are slightly attenuated, once we control for changes in schooling across sectors.<sup>21</sup>

### **6.3. Interpretation**

Our results can be interpreted in light of the arguments sketched in section 3. An increase in the enforcement of mandated benefits in the formal sector leads to reduction in formal wages, especially at the top of the distribution. Similarly, unemployment increases for two reasons. On the one hand, at the bottom of the formal wage distribution wages cannot adjust, and some employees are likely to be dismissed. On the other hand, if the fall in wages is smaller than the increase in the value of other formal job benefits (because of wage rigidity, or because the value workers put on benefits is higher than their cost to the firm), formal jobs become more attractive, inducing self-employed workers to search for work in the formal sector, in spite of a higher risk of unemployment.<sup>22</sup> If these jobs are at the bottom of the distribution of formal wages, it is natural that those workers leaving the self-employment sector have low levels of schooling.

If the cost of mandated benefits to the firm is below the value they have to workers (e.g., tax free job severance payments, health and safety on the job), then an increase in mandated benefits could explain a rise in formal sector employment, since this sector becomes more attractive. The contraction in the supply of self-employed workers causes an increase in their wages. Formal sector employment may also increase due to worker registration (through direct action of labor inspectors, or indirectly through a deterrent effect).

---

<sup>21</sup> We estimate a simpler specification where the instrument for enforcement is distance alone, and not distance interacted with state inspectors. The reason this is not our main specification, we are not confident that distance alone is a valid instrument, although we conjecture that the bias should not be very large. The findings (not reported) show that, for most outcomes, the results are consistent with those reported in the paper. The main differences relate to income inequality, where coefficients are insignificant. Nevertheless, we still find a strong reduction on the formal wage premium, measured relatively to informal or relatively to self-employed workers.

<sup>22</sup> Using data from IPEA, we can compute the number of people searching for a job in each city, by subtracting the number of employed from the number of active individuals. The problem with this measure is that we cannot distinguish search in the formal and in the informal sector. If we regress the (log) number of individuals searching on enforcement (instrumented) we estimate that a one standard deviation increase in enforcement increases total search by 1/3 of a standard deviation.

Finally, it is interesting to notice that there are no statistically significant effects neither on wages nor employment of informal wage earners. As suggested in the literature, they form a segmented branch of the labor market in Brazil, shielded from changes in the economy.

We have ignored corruption so far. Increased enforcement may indicate more frequent corruption opportunities (not stricter regulation), especially for firms breaking the law. One way to model this is as an increase in the costs of hiring either formal or informal workers. However, corruption by itself cannot explain out data since it would imply a decline in wages in both sectors, and possibly a decline in employment in both sectors.

#### **6.4. Inequality**

The empirical findings suggest that income inequality declines when enforcement increases. The second panel of table 7 shows a compression in the distribution of wages both in the formal and in the informal (self-employment) sectors. Moreover, there is a decline in wage differentials between formal and self-employed workers. However, we also have to consider that the non-employment rate increases with enforcement, and this could lead to higher levels of city income inequality. The results in table 8 show that changes in non-employment are not uniform across the distribution of income. We consider 6 groups of individuals, according to their position in the distribution of household per capita income: 0-10 percentile, 10-25, 25-50, 50-75, 75-90, and 90-100. Enforcement affects non-employment mostly for the poorest individuals in society, so it is not surprising that, in spite of the decline in inequality, we observe small decreases in poverty. Table 8 also shows that losses in employment are large among females, low skilled workers, and young workers, which are especially vulnerable groups (see also Heckman and Pages, 2004).

In sum, these findings clearly show that it is difficult to reach the poor using labor market policy (we estimate small impacts of enforcement on poverty in table 4). The reason is that the poor are too much outside the margins of policy where regulation operates, echoing the results of several analyses of minimum wages (e.g., Almeida and Bourguignon, 2006).

### **7. Conclusion**

This paper studies the effect of an increase of enforcement of labor regulation on unemployment and inequality, using city level data from Brazil. We explore variation in the enforcement of labor market regulations using a new administrative dataset with information on the intensity of enforcement activity for all cities in Brazil. We interpret our findings in light of standard multi-

sector models of the labor market in developing countries, which integrate formal and informal sectors and unemployment in a single framework.

We find that an increase in enforcement leads to higher unemployment but lower inequality. We also document that: i) employment flows between the formal and self-employment sectors, but informal wage earners are in a segmented sector of the economy; ii) mandated benefits are borne by workers in the form of lower wages at the top of the formal wage distribution, but not at the bottom where downward wage rigidity may be important; iii) as a result, formal jobs at the bottom of the wage distribution become more attractive, inducing those who are low skilled and self-employed to search for employment in the formal sector.

Robust standard errors in brackets, \* significant at 10%; \*\* significant at 5%; \*\*\* significant at 1%. The table reports the least squares estimates of the regression of each of the variables reported at the top of each row on the distance to the nearest labor office (hours) interacted with the log number of labor inspectors in the state. The controls are state dummies, distance to the nearest labor office, its square and interactions with state level variables, distance to the state capital city, its square and interactions with the number of inspectors per firm in the state and interactions with other state variables, city transportation costs, its square and interactions with the number of inspectors per firm in the state and interactions with other state variables, city altitude, city latitude and city longitude. Other state variables include average access to justice, political concentration, management quality in public administration and the GDP per capita in the state. City transportation cost is the transport cost between each city and the nearest capital city in 1995. We also include the log of total population, per capita income, average years of schooling and share of population in urban areas, in 1970, 1980, and 1991 (variables describ

Standard errors in brackets, \* significant at 10%; \*\* significant at 5%; \*\*\* significant at 1%. Panel A reports the estimated coefficients of the regression of the city variables reported at the top of each column on

the log of the number of inspected firms per firm in the city, controlling for state level dummy variables and several city level characteristics. Panel B reports the instrumental variable estimates using city distance to the nearest labor office interacted with the number of state level inspectors per firm in the state as an instrument for enforcement. City level characteristics include distance to the nearest labor office, its square and interactions with state level measures of institutional quality, distance to the state capital city, its square and interactions with the number of inspectors per firm in the state and interactions with state level measures of institutional quality, city transportation costs, its square and interactions with the number of inspectors per firm in the state and interactions with state level measures of institutional quality, city altitude, city latitude and city longitude. It also includes the city level controls for income per capita, population, average schooling and share of urban population in 1991, 1980 and 1970.

Figure 1. Increase in the Cost of Mandated Benefits Equally Valued by Firms and Workers

Figure 2. Increase in the Cost of Mandated Benefits Valued More Highly by Workers than Firms

Figure 3. Increase in the Cost of Hiring Informal Workers

Figure 4A: Effect of Distance on Enforcement Across Brazilian States

Figure 4B: Effect of Distance on Informality Across Brazilian States

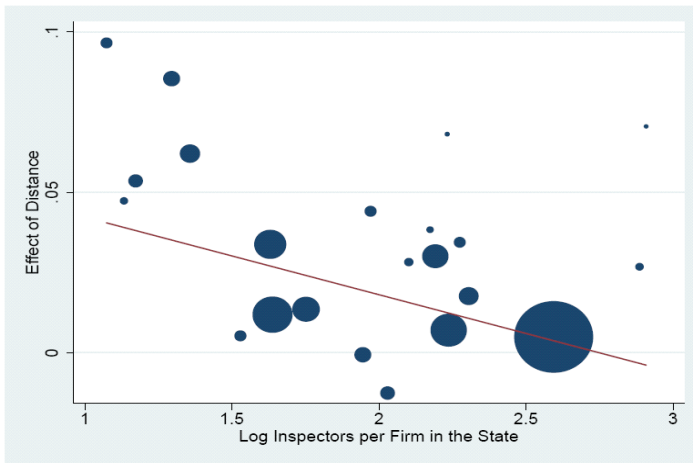

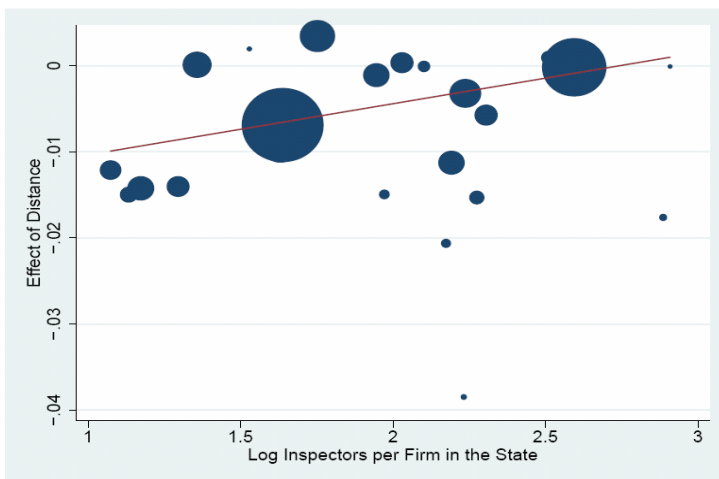

Figure 4C: Effect of Distance on Unemployment Across Brazilian States

Note: In Figure 4A we run, for each Brazilian state, a regression of the degree of enforcement (measured by the log of number of inspections per firm in the city in 2002) on distance to the nearest enforcement office (measured in hours of travel by car). Each circle represents a coefficient of one of these regressions, which is plotted against the log number of inspectors per firm in the state (coeff.=0.138, s.e.=0.029). The size of each circle is the inverse of the standard error of the estimated coefficient. Figures 4B and 4C can be interpreted analogously. Figure 4B plots the coefficients of a regression of the share of informal workers (in 2000) in each city on distance, against the log number of inspectors per firm in the state (coeff.=0.024, s.e.=0.006), while Figure 4C plots the coefficients of a regression of the unemployment rate at the city level (in 2000) on distance, against the log number of inspectors per firm in the state (coeff.=0.006, s.e.=0.002).

Figure 5A: Effect of Distance on Past Informality Across States

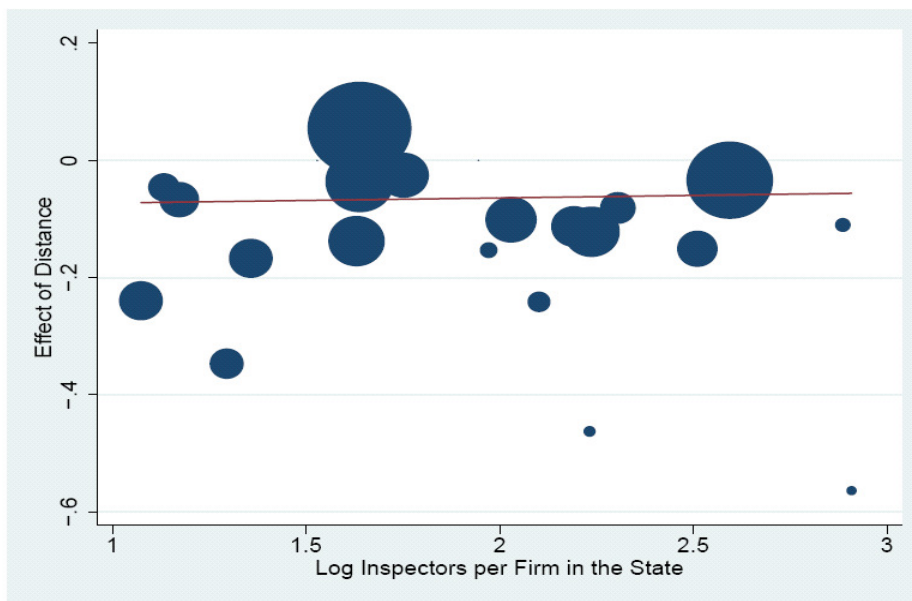

Figure 5B: Effect of Distance City GDPpc in 1980 Across Brazilian States

Note: In Figure 5A we run, for each Brazilian state, a regression of the share of informal workers in the city in 1980 on distance to the nearest enforcement office (measured by hours of travel by car). Each circle represents a coefficient of one of these regressions, which is plotted against the log number of inspectors per firm in the state (coeff.= $-0.015$ , s.e.= $0.014$ ). The size of each circle is the inverse of the standard error of the estimated coefficient. Figure 5B can be interpreted analogously. Figure 5B plots the coefficients of a regression of the GDP per capita in the city in 1980 on distance, against the log number of inspectors per firm in the state (coeff.= $0.009$ , s.e.= $0.046$ ).

Table A1: Proportion of Labor Market Fines in the City (2002)

	Obs	Average	SD
	(1)	(2)	(3)
Worker's Formal Registration	1,453	0.22	0.31
Mandatory Work Period	1,453	0.10	0.20
Mandatory Work Pause Period	1,453	0.09	0.17
Wage	1,453	0.09	0.18
FGTS Contributions	1,453	0.26	0.32
Other (incl. Health, Security Restrictions)	1,453	0.23	0.29

Robust standard errors in brackets, \* significant at 10%; \*\* significant at 5%; \*\*\* significant at 1%. The table reports the least squares estimates of the regression of each of the variables reported in each row on the distance to the nearest labor office (hours) interacted with the number of labor after controlling for all the variables as in column (3) of table 4. Households with piped water, sanitation and electricity are measured with the logarithm of number of households with these amenities normalized by the total number of individuals in the city. When not reported city characteristics refer to either year 2000 or 2002 depending on the data availability. More details on the construction of the variables are provided in the Data section.

Table A5: Enforcement and City Outcomes (2000): Robustness to Additional City, Firm and Worker Controls

Dependent Variable:	Share Informal Workers	Poverty Rate	Unemployment Rate	Inequality Index
	(1)	(2)	(3)	(4)

## Summary Findings

We study the effect of enforcement of labor regulation in Brazil, an economy with a large informal sector and strict labor law. Enforcement affects mainly the degree of compliance with mandated benefits (severance pay; health and safety) in the formal sector; and the registration of informal workers. We find that stricter enforcement leads to higher unemployment but lower income inequality. We also show that, at the top of the formal wage distribution, workers bear the cost of mandated benefits by receiving lower wages. This is not true at the bottom, because of downward wage rigidity. As a result, formal sector jobs at the bottom of the wage distribution become more attractive, inducing the low skilled self-employed to search for formal jobs.

HUMAN DEVELOPMENT NETWORK

### About this series...

Social Protection Discussion Papers are published to communicate the results of The World Bank's work to the development community with the least possible delay. The typescript manuscript of this paper therefore has not been prepared in accordance with the procedures appropriate to formally edited texts. The findings, interpretations, and conclusions expressed herein are those of the author(s), and do not necessarily reflect the views of the International Bank for Reconstruction and Development / The World Bank and its affiliated organizations, or those of the Executive Directors of The World Bank or the governments they represent. The World Bank does not guarantee the accuracy of the data included in this work.
