# On Functional Central Limit Theorems for Dependent, Heterogenous Tail Arrays with Applications to Tail Index and Tail Dependence Estimators 

Jonathan B. Hill*<br>Dept. of Economics<br>Florida International University

November 27, 2006

#### Abstract

We establish functional central limit theorems for a broad class of dependent, heterogeneous tail arrays encountered in the extreme value literature, including extremal exceedances, tail empirical processes and tail empirical quantile processes. We trim dependence assumptions down to a minimum by constructing extremal versions of mixing and Near-EpochDependence properties, covering mixing, ARFIMA, FIGARCH, bilinear, random coefficient autoregressive, nonlinear distributed lag and Extremal Threshold processes, and stochastic recurrence equations.

Of practical importance our theory can be used to characterize the functional limit distributions of sample means and covariances of tail arrays, including popular tail index estimators, the tail quantile function, and multivariate extremal dependence measures under substantially general conditions.

1. INTRODUCTION This paper presents functional central limit theorems of the form

$$
\sum_{t=1}^{n(\xi)} X_{n, t}(u) \Rightarrow X(\xi, u), \text { where } \xi, u \in[0,1],
$$

for dependent, heterogenous tail arrays $\left\{X_{n, t}(u)\right\}$ in $D[0,1]$, with $X(\xi, u)$ a Gaussian process. $n(\xi)$ denotes a non-decreasing integer sequence, $n(\xi) \rightarrow \infty$

[^0]as $n \rightarrow \infty$. We require the functional array $X_{n, t}(u)$ to be approximable by an "extremal" martingale difference array, and to satisfy
\[

$$
\begin{equation*}
\sup _{t} \sup _{u \geq 1}\left(E\left|X_{n, t}(u)\right|^{r}\right)^{1 / r}=O\left(n^{-a(r)}\right) \tag{1}
\end{equation*}
$$

\]

for some non-stochastic function $a(r) \in(0,1 / 2]$ and all $r \geq 1$. For non-stochastic sequences $b_{n(\xi)} \rightarrow \infty$ and $k_{n}(\xi) \rightarrow \infty$ property (1) covers for all $r \geq 1$ extreme threshold exceedances $\max \left\{\ln X_{t} / b_{n(\xi)}, 0\right\}$, tail empirical processes $1 / k_{n}(\xi)^{1 / 2} \sum_{t=1}^{n(\xi)} I\left(X_{t}\right.$ $\left.>b_{n(\xi)} u\right)$, and tail empirical quantile processes $X_{\left(\left[k_{n}(\xi)\right]\right)} \geq X_{\left(\left[k_{n}(\xi)\right]+1\right)} \geq \ldots$ See Section 3.

Tail array sums are critical for risk management, damage and catastrophe modeling in the engineering, financial, actuarial and meteorological sciences, and the modeling of explosive economic events like asset market collapses, hyperinflation and cross-market contagion. See, e.g., Mittnik and Rachev (1993), Embrechts, Kluppelberg, and Mikosch (1997) and Finkenstadt and Rootzén (2003).

Moreover, exceedance and tail empirical processes provide a theoretical foundation from which to analyze tail index and tail dependence estimators. See, e.g., Hsing (1991).

Our research is motivated by the popular application of tail shape estimators and tail dependence measures on highly dependent and heterogeneous data, including equity, bond and exchange rate returns, prices, insurance claims, and climate extremes. See Brown Katz (1993), Hsieh (1999), Kysely (2002), and Galbraith and Zernov (2004), and Schmidt and Stadtmüller (2006) to name a very few. In both cases existing theory can only handle limited forms of dependence and heterogeneity.

### 1.1 Tail Index Estimation

Consider estimating the tail index parameter of a process $\left\{X_{t}\right\}$ on $[0, \infty)$ with a regularly varying tail:
(2) $\quad P\left(X_{t}>x\right)=x^{-\alpha} L(x)$, as $x \rightarrow \infty$, where $L$ is slowly varying.
B. Hill (1975) proposed a simple estimator of $\alpha^{-1}$ which we generalize to a functional sub-sample. If $X_{(i)}>0$ denotes the $i^{t h}$ order statistic $X_{(1)} \geq X_{(2)}$ $\geq \ldots$, and $[z]$ the nearest integer, $[z] \geq z$, the estimator is

$$
\hat{\alpha}_{n}^{-1}(\xi):=1 / k_{n}(\xi) \sum_{t=1}^{n(\xi)}\left(\ln X_{t} / X_{\left(\left[k_{n}(\xi)\right]+1\right)}\right)_{+}
$$

for some sequence $k_{n}(\cdot):[0,1] \rightarrow \mathbb{N}, k_{n}(\xi) \rightarrow \infty$ as $n(\xi) \rightarrow \infty, k_{n}(\xi) / n(\xi)$ $\rightarrow 0$. Fan, Quintos and Phillips (2001) deliver a functional distribution limit for $\hat{\alpha}_{m}^{-1}(\xi)$ under an iid assumption. In the non-functional case asymptotic normality has been established for iid and strong mixing processes (Hall 1982, Hall and Welsh 1985, Hsing 1991), and for processes with extremes that are Near-Epoch-Dependent on the extremes of a mixing process (Hill 2005b).

The Extremal Near Epoch Dependence [E-NED] property of Hill (2005b) has substantial practical advantages over mixing and conventional NED (Gallant
and White 1988), and $L_{p}$-weak dependence (Wu 2006, Wu and Manli 2005) properties because it imposes memory and heterogeneity restrictions only on extremes: the Hill-estimator uses information strictly from the extreme sample tail, hence all assumptions governing non-extremes are superfluous. The ENED property will be important for the analysis of many heavy-tailed time series in finance, macroeconomics and meteorology in which extremes appear to cluster, and for which the analyst does not want to specificy a model for the non-extremes.

The E-NED property only requires computation of a conditional probability, it is typically straightforward to verify, and it characterizes any mixing process, non-mixing processes, essentially any $L_{p}$-NED process, $p>0$, linear distributed lags and linear conditional volatility processes with short or long memory, bilinear processes, random coefficient autoregressions, and many nonlinear distributed lags $X_{t}=g\left(X_{t-1}, \epsilon_{t}\right)$ where $\epsilon_{t}$ need only be $L_{p}$-bounded. In particular, the Extremal-NED property can characterize processes with highly dependent non-extremes (e.g. the non-extremes are a random walk) that are neither NED nor $L_{p}$-weakly dependent. See Hill (2005b).

### 1.2 Tail Dependence Estimation

Consider two stochastic processes $\left\{X_{1, t}, X_{2, t}\right\}$ with marginal distributions described by (2) with indices $\alpha_{1}>0$ and $\alpha_{2}>0$. The tail dependence coefficient for $X_{1, t}$ and $X_{2, t}$ is

$$
\begin{align*}
& \rho_{\alpha, n}(h)=\left(n / k_{n}\right)\left[P\left(X_{1, t}>b_{1, n}, X_{2, t-h}>b_{2, n}\right)\right.  \tag{3}\\
&\left.-P\left(X_{1, t}>b_{1, n}\right) P\left(X_{2, t-h}>b_{2, n}\right)\right]
\end{align*}
$$

for some sequences of thresholds $b_{i, n} \rightarrow \infty, k_{n}=o(n)$, and $k_{n} \rightarrow \infty$ as $n \rightarrow \infty$. Tail dependence has been modeled extensively in the case of bivariate regularly varying processes that are marginally iid. See Ledford and Tawn (1996, 1997), Coles, Hefferman and Tawn (1999), Breymann, Dias and Embrechts (2003), Embrechts, Lindskog and McNeil (2003) and Hefferman and Tawn (2004). Schmidt and Stadtmüller (2006) analyze a non-parametric estimator of $\rho_{\alpha, n}(h)$ only for iid pairs $\left\{X_{1, t}, X_{2, t}\right\}$ with a parametric bivariate tail shape. The assumption of independence for the marginal distributions substantially restricts the types of bivariate environments in which tail dependence estimators may be applied, entirely omits the possibility of serial extremal dependence ( $X_{1, t}=X_{2, t}$ ), and superfluously imposes structure on non-extremes.

### 1.3 Limit Theory for Tail Arrays

Rootzén, Leadbetter, and de Haan (1998) analyze general tail array sums under a mixing condition, and Hsing $(1991,1993)$ develops limit theory for a subset of such tail array sums in the strong mixing case. See also Rootzén, Leadbetter, and de Haan (1990) and Leadbetter and Rootzén (1993). Rootzén (1995), Drees (2002) and Eihnmal and Lin (2003) consider functional limit theory for iid and mixing tail empirical processes in $C[0,1]$ and $D[0, \infty)$. Typically the imposed restrictions are rather abstract (Rootzén 1995; Eihnmal and Lin 2003), and
have only been exemplified for linear non-extremal processes (Eihnmal and Lin 2003: asymptotically independent extremes, AR(1)). See also Csörgö, Csörgö, Horváth, and Mason (1986), Mason (1988), and Eihnmal (1990).

Moreover, the best extant central limit theory for dependent, heterogeneous arrays (de Jong 1997, Wu and Manli 2005) does not apply to tail arrays (see Hill 2006), and some processes with highly dependent non-extremes are neither NED nor $L_{p}$-weakly dependent.

In this paper we characterize sufficient conditions for functional central limit theorems for tail arrays under (reasonably) minimal assumptions regarding memory and heterogeneity. We use an extremal mixing property, and we exploit a functional version of the Extremal-Near-Epoch-Dependence property in Hill (2005b).

In the main result of the paper, Theorem 1, we deliver a functional limit theory for Extremal-NED arrays. In Section 3 we provide examples of limit theory for specific tail arrays, and Section 4 contains examples of processes that are Extremal-NED. The theory developed here essentially unifies and goes well beyond the disparate theory and environments treated in Rootzén et al (1990), Leadbetter and Rootzén (1993), Rootzén (1995), Drees (2002) and Eihnmal and Lin (2003). Proofs of the main results are in Appendix 1 and Appendix 2 contains supporting lemmata.

Our theory can equally handle sample means and covariances of tail arrays. Thus, we apply the theory to a complete asymptotic analysis of the Hill-estimator $\hat{\alpha}_{n}^{-1}(\xi)$ the tail empirical quantile estimator $X_{\left(\left[k_{n}(\xi)\right]\right)}$, and a tail dependence coefficient estimator $\hat{\rho}_{\alpha, n(\xi)}(h)$ in Section 5. Both results are the most general available in either literature, and we anticipate the applicability of the theory developed here for other tail-array based estimators.

Throughout $\rightarrow$ variously denotes convergence in probability or finite distributions; $\Rightarrow$ denotes weak convergence on some function space. $(z)_{+}:=\max \{z, 0\}$. Gaussian elements of function spaces have zero means. $K>0$ denotes a finite constant that may change in value based on the context.
2. ASSUMPTIONS and MAIN RESULTS We first state primitive tail array characteristics. We then define the memory properties used throughout this paper, and present the main results.

Let $\left\{X_{t}\right\}=\left\{X_{t}:-\infty<t<\infty\right\}$ be a stochastic process on some probability measure space $(\Omega, \Im, \mu), \Im=\sigma\left(\cup_{t \in \mathbb{Z}} \Im_{t}\right), \Im_{t-1} \subset \Im_{t} \equiv \sigma\left(X_{\tau}: \tau \leq t\right)$. We will work with the two dimensional cadlag space

$$
D_{2}:=D([\underline{\xi}, 1] \times[0,1]), \forall x \in D_{2}: x(1, u)=x(1-, u),
$$

for some $\underline{\xi} \in(0,1]$. The theory of this paper is greatly expedited by bounding $\xi$ away from 0 , and $x(1, u)=x(1-, u)$ solves the right end-point problem with cadlag functions. Neither restriction reduces the generality of the main results by much.

Let $X_{n, t}(u)$ be a $D[0,1]$-valued stochastic array, and define the corresponding $D_{2}$-functional

$$
X_{n}(\xi, u):=\sum_{t=1}^{n(\xi)} X_{n, t}(u)
$$

$n(\xi)$ is right continuous, non-decreasing in $\xi, n(\xi) \rightarrow \infty$ as $n \rightarrow \infty, n\left(\xi_{1}\right)-$ $n\left(\xi_{2}\right) \rightarrow \infty \forall \xi_{1} \geq \xi_{2}, n(0)=0$, and $n(1-)=n(1) \leq n$.

DEFINITION [Tail Array] $\left\{X_{n, t}(u)\right\}$ is an $L_{r}$-Functional Tail Array of $\left\{X_{t}\right\}$ if $X_{n, t}(u) \in D[0,1]$, $\sup _{t} \sup _{u \in[0,1]}\left\|X_{n, t}(u)\right\|_{r}=O\left(n^{-a(r)}\right)$ for some function $a:[1, \infty) \rightarrow(0,1 / 2]$; and $\eta(\xi, u):=\lim _{n \rightarrow \infty}\left\|X_{n}(\xi, u)\right\|_{2}$ exists for all $\xi$, where $\eta(\xi, u)$ is a non-decreasing function on $[0,1]^{2}, \eta(0, \cdot)=0$, $\eta(1, \cdot)=1$.

Remark 1: We refer to $a(r)$ as the $r^{t h}$-moment index. See Section 4 for examples of $L_{r}$-Tail Arrays.

Our main result uses a big block/little block argument, cf. Berstein (1927). Define the sequences $g_{n}(\underline{\xi}), l_{n}(\underline{\xi})$ and $r_{n}(\xi), \xi \in[\underline{\xi}, 1]$, as follows: $g_{n}(\underline{\xi}) \rightarrow \infty$ as $n \rightarrow \infty$ and

$$
\begin{aligned}
& 1 \leq g_{n}(\underline{\xi})=o(n(\underline{\xi})), \quad 1 \leq l_{n}(\underline{\xi}) \leq g_{n}(\underline{\xi})-1 \leq n(\underline{\xi})-1 \text { where } l_{n}(\underline{\xi}) \rightarrow \infty ; \\
& l_{n}(\underline{\xi}) / g_{n}(\underline{\xi}) \rightarrow 0, \quad r_{n}(\xi)=\left[n(\xi) / g_{n}(\underline{\xi})\right] \text { where } r_{n}(\xi) \rightarrow \infty .
\end{aligned}
$$

We omit the common argument $\xi$ for clarity and write $g_{n}$ and $l_{n}$. Notice $r_{n}(0)$ $=0$ and $r_{n}\left(\xi_{1}\right) \leq r_{n}\left(\xi_{2}\right) \forall \xi_{2} \geq \bar{\xi}_{1}$. Define the blocks

$$
Z_{n, i}=Z_{n, i}(u):=\sum_{t=(i-1) g_{n}+l_{n}+1}^{i g_{n}} X_{n, t}(u)
$$

Under mild assumptions concerning memory and heterogeneity we will prove

$$
X_{n}(\xi, u)=\sum_{i=1}^{r_{n}(\xi)} \sum_{t=(i-1) g_{n}+l_{n}+1}^{i g_{n}} Z_{n, i}(u)+o_{p}(1) \Rightarrow X(\xi, u)
$$

Our main result relies on a new functional limit theorem for Tail Arrays that are approximable by martingale difference array. See Lemma A. 1 of Appendix 1. In order to ensure the approximation condition holds for a wide array of processes we construct extremal versions of mixing and near-epoch-dependence properties. Let $\left\{\epsilon_{t}\right\}$ be a stochastic process with $\sigma$-algebra

$$
G_{t}:=\sigma\left(\epsilon_{\tau}: \tau \leq t\right)
$$

Write $G_{b}^{a}:=\sigma\left(\epsilon_{t}: a \leq t \leq b\right)$. Let $\left\{\pi_{n, t}\right\}$ be a sequence of constant real thresholds, $\pi_{n, t} \rightarrow \infty$ as $n \rightarrow \infty$, and denote by $\left\{E_{n, t}\right\}$ a $G_{t}$-measurable extremal process. Examples include the extreme event $I\left(\left|\epsilon_{t}\right|>\pi_{n, t}\right)$, exceedance $\left(\left|\epsilon_{t}\right|-\right.$ $\left.\pi_{n, t}\right)_{+}$, or value $\left|\epsilon_{t}\right| \times I\left(\left|\epsilon_{t}\right|>\pi_{n, t}\right)$.

Denote by $\digamma_{n, s}^{t} \in G_{s}^{t}$ the sigma sub-algebra induced by the extremal event

$$
\digamma_{n, s}^{t}:=\sigma\left(E_{n, \tau}: 1 \leq s \leq \tau \leq t \leq n\right)
$$

and define the coefficients

$$
\begin{aligned}
& \varepsilon_{q_{n}} \equiv \sup _{A_{n, t} \in F_{n, 1}^{t}, B_{n, t+q_{n} \in F_{n, t+q_{n}}^{n}: 1 \leq t \leq n-q_{n}}\left|P\left(A_{n, t} \cap B_{n, t+q_{n}}\right)-P\left(A_{n, t}\right) P\left(B_{n, t+q_{n}}\right)\right|}^{\varpi_{q_{n}} \equiv \sup _{A_{n, t} \in F_{n, 1}^{t}, B_{n, t+q_{n}} \in F_{n, t+q_{n}}^{n}: 1 \leq t \leq n-q_{n}}\left|P\left(B_{n, t+q_{n}} \mid A_{n, t}\right)-P\left(B_{n, t+q_{n}}\right)\right|,}
\end{aligned}
$$

where $\left\{q_{n}\right\}$ is a sequence of integers, $1 \leq q_{n} \leq n, q_{n} \rightarrow \infty$ as $n \rightarrow \infty$..
DEFINITION [E-Mixing] If $q_{n}^{\lambda} \varepsilon_{q_{n}} \rightarrow 0$ as $n \rightarrow \infty$ for some all $\left\{q_{n}\right\}$ we say $\left\{\epsilon_{n, t}\right\}$ is Extremal-Strong Mixing with size $\lambda>0$. If $h\left(q_{n}\right)^{\lambda} \varpi_{q_{n}} \rightarrow$ 0 as $n \rightarrow \infty$ for all $\left\{q_{n}\right\}$ we say $\left\{\epsilon_{t}\right\}$ is Extremal-Uniform mixing with size $\lambda>0$.

Remark 1: The E-mixing property is simply a canonical uniform or strong mixing property assigned to the extremal process $\left\{E_{n, t}\right\}$ as $n \rightarrow \infty$, hence any measurable function of a finite sequence $\left\{E_{n, t}, E_{n, t-1}, \ldots, E_{n, t-h}\right\}$ is E-mixing, $h \geq 1$. Strong (uniform) mixing process implies E-strong (uniform) mixing, and well known inequalities hold for E-mixing processes. Cf. Ibragimov (1962) and Serfling (1968). See Hsing (1991: p.) for a similar construction.

Remark 2: The E-strong mixing property is related to Leadbetter's (1974) D-mixing property, cf. Leadbetter, Lindgren and Rootzén (1983). D-mixing is not uniform and therefore does not carry over to measurable functions of D-mixing random variables, a trait we explicitly exploit in the proof of the supporting Lemma A.4.

Let $\left\{\digamma_{n, t}\right\}$ be an arbitrary array of $\sigma$-fields.

## DEFINITION [FE-NED]

1. $\left\{X_{t}\right\}$ is $L_{p}$-Functional-Extremal-NED, $p>0$, with size $-1 / 2$, on some $\left\{\digamma_{n, t}\right\}$ if some $L_{r}$-Functional-Tail Array $\left\{X_{n, t}(u)\right\}$ based on $\left\{X_{t}\right\}$ satisfies

$$
\begin{equation*}
\| X_{n, t}(u)-E\left[X_{n, t}(u) \mid \digamma_{n, t-q}^{t+q} \|_{p} \leq d_{n, t}(u) \varphi_{q_{n}}\right. \tag{4}
\end{equation*}
$$

The Lebesgue measurable function array $\left\{d_{n, t}(u)\right\}, d_{n, t}:[0,1] \rightarrow \mathbb{R}_{+}$, satisfies $\sup _{u \in[0,1], t \geq 1} d_{n, t}(u)=O\left(n^{-a(r)}\right)$. The coefficients $\left\{\varphi_{q_{n}}\right\}$ satisfy $n^{1 / 2-a(r)} q_{n}^{1 / 2} \varphi_{q_{n}} \rightarrow 0$.
2. Define $Y_{n, t}\left(u_{1}, u_{2}\right):=X_{n, t}\left(u_{1}\right)-X_{n, t}\left(u_{2}\right)$. Then
(5) $\left\|Y_{n, t}\left(u_{1}, u_{2}\right)-E\left[Y_{n, t}\left(u_{1}, u_{2}\right) \mid \digamma_{n, t-q}^{t+q}\right]\right\|_{p} \leq\left(\tilde{d}_{n, t} \times\left|u_{2}-u_{1}\right|^{1 / p}\right) \times \varphi_{q_{n}}$,
$\forall u_{1}, u_{1} \in[0,1]$, where $\sup _{t} \tilde{d}_{n, t}=O\left(n^{-a(r)}\right)$.

Remark 1: The imposition of $L_{p}$-boundedness is irrelevant for popular tail arrays that are inherently $L_{r}$-bounded $\forall r \geq 1$. The second property (5) is imposed to handle tightness of sequences of distributions of $\left\{X_{n}(u, \xi)\right\}$.

Remark 2: On the surface the FE-NED property (4) is identical to the canonical NED property, cf. Gallant and White (1988) and Davidson (1994). Thus, the "constants" $d_{n, t}(u)$ effectively allow the "coefficients" $\varphi_{q_{n}}$ to be scalefree. That we only impose the NED property on a Tail Array $X_{n, t}(u)$ of $X_{t}$ is a crucial distinction. The FE-NED property is uniquely suited to characterize dependence in extremes simply by exploiting an appropriate Tail Array $X_{n, t}(u)$ of $X_{t}$, and will allow us to deliver invariance principles for processes with nonextremes that are too dependent to be NED or $L_{p}$-weakly dependent.

Remark 3: We say $\left\{X_{t}\right\}$ is FE-NED on $\left\{\epsilon_{t}\right\}$ if it is FE-NED on some array of $\sigma$-fields $\left\{\digamma_{n, t}\right\}$ induced by $\left\{\epsilon_{t}\right\}$.

## Assumption 1

(a) $\left\{X_{t}\right\}$ is $L_{2}$-FE-NED of size $-1 / 2$ on an E-strong mixing base $\left\{\epsilon_{n, t}\right\}$ of size $\lambda=r /(r-2), r>2$, or E-uniform mixing base of size $\lambda=r /[2(r$ $-1)], r \geq 2$.
(b) For some finite function $\kappa(\xi, \delta) \geq 1$ and each $\xi \in[\underline{\xi}, 1-\delta], \delta \in[0,1]$,

$$
\left|r_{n}(\xi+\delta) / r_{n}(\xi)-\kappa(\xi, \delta)\right| \rightarrow 0
$$

Moreover $2 a(4)+a(2)>1,2 a(2 r)>a(r)$. Furthermore

$$
g_{n}=o\left(n^{\min \{[2 a(4)+a(2)-1] / 2,2 a(2 r)-a(r)\}}\right)
$$

THEOREM 1 Under Assumption $1, X_{n}(\xi, u) \Rightarrow X(\xi, u)$ on $D_{2}$ where $X(\xi, u)$ is Gaussian with independent increments and covariance function $E\left[X\left(\xi_{i}, u_{i}\right) X\left(\xi_{j}, u_{j}\right)\right]$.

Remark 1: The rate $g_{n}=o\left(n^{\min \{[2 a(4)+a(2)-1] / 2,2 a(2 r)-a(r)\}}\right)$ is always possible, and merely expedites a proof that the Lindeberg condition holds. The assumption $2 a(4)+a(2)>1$ and $2 a(2 r)-a(r)>0$ guarantee $g_{n} \rightarrow \infty$ as $n$ $\rightarrow \infty$, and ensure a Lindeberg condition holds for Tail Arrays, cf. Lemma A.2. The restrictions imply, for example, $a(r)=1 / r$ for all $r \geq 1$ is not covered here. In Section 3 we demonstrate that at least three popular Tail Arrays satisfy all restrictions on $a(r)$.

Remark 2: The requirement $\left|r_{n}(\xi+\delta) / r_{n}(\xi)-\kappa(\xi, \delta)\right| \rightarrow 0$ further restricts $g_{n}$ in order to ensure uniform tightness on $D_{2}$, cf. Lemma A.3. For example, if $n(\xi)=[n \xi]$ and $g_{n}=\left[(n \underline{\xi})^{\theta}\right]$ for some $\theta \in(0,[2 a(4)+a(2)-1] / 2)$ then $\kappa(\xi, \delta)=(1+\delta / \xi)^{1-\theta}<\infty \forall \xi \geq \underline{\xi}>0$.

Remark 3: $\quad$ For any fixed $u \in[0, \overline{1}]$ if $\eta(\xi, \cdot)=\lim _{n \rightarrow \infty}\left\|X_{n}(\xi, \cdot)\right\|_{2}=\xi$ then $X(\xi, \cdot)$ is Brownian motion. Otherwise $X(\xi, \cdot)$ is the so-called transformed Brownian motion of Davidson (1994: p. 485) and de Jong and Davidson (2000).
3. INVARIANCE PRINCIPLES We now characterize invariance principles for specific extremal processes $\left\{X_{n, t}\right\}$. Assume $F_{t}(x):=P\left(X_{t} \leq x\right)$ has support on $[0, \infty)$, and $\bar{F}_{t}(x):=P\left(X_{t}>x\right)$ is regularly varying at $\infty$ : for all $t$ there exists some $\alpha>0$ such that for all $\lambda>0$,

$$
\begin{equation*}
\bar{F}_{t}(\lambda x) / \bar{F}_{t}(x) \rightarrow \lambda^{-\alpha} \text { as } x \rightarrow \infty \quad \Leftrightarrow \quad \bar{F}_{t}(x)=x^{-\alpha} L(x), \quad x>0 \tag{6}
\end{equation*}
$$

for some slowly varying function $L(x)$. The class of distributions satisfying (6) includes the domain of attraction of the stable laws, coincides with the maximum domain of attraction of the extreme value distributions $\exp \left\{-x^{-\alpha}\right\}$, and characterizes many stochastic recurrence equations (e.g. GARCH). See de Haan (1970), Leadbetter et al (1983), Bingham, Goldie and Teugels (1987), Resnick (1987) and Basrak et al (2002).

Let $\bar{F}_{t}(x) / \bar{F}_{t}(x-) \rightarrow 1$ as $x \rightarrow \infty$. Then there exists sequences $k_{n}=o(n)$ and $b_{n}\left(k_{n}\right)=o(n), b_{n}\left(k_{n}\right) \rightarrow \infty$, satisfying (see Leadbetter et al, 1983)
(7) $\lim _{n \rightarrow \infty}\left(n / k_{n}\right) P\left(X_{t}>b_{n}\right)=1$.

Consider the intermediate case: $k_{n} \rightarrow \infty$ as $n \rightarrow \infty, n / k_{n} \rightarrow 0$, and define

$$
\begin{align*}
& X_{n, t}:=k_{n}^{-1 / 2}\left(\left(\ln X_{t} / b_{n}\left(k_{n}\right)\right)_{+}-E\left[\left(\ln X_{t} / b_{n}\left(k_{n}\right)\right)_{+}\right]\right),  \tag{8}\\
& X_{n, t}^{*}(u):=k_{n}^{-1 / 2}\left(I\left(x_{t}<v_{n}\left(k_{n}\right) u\right)-E\left[I\left(x_{t}<v_{n}\left(k_{n}\right) u\right)\right]\right), u \in[0,1]
\end{align*}
$$

where

$$
x_{t}:=\bar{F}\left(X_{t}\right) \text { and } v_{n}\left(k_{n}\right):=\bar{F}\left(b_{n}\right) \rightarrow 0 \text { as } n \rightarrow \infty .
$$

Notice (6) and (7) imply

$$
v_{n}\left(k_{n}\right) \sim k_{n} / n, \quad \text { and as } n \rightarrow \infty x_{t}<v_{n}\left(k_{n}\right) u \Leftrightarrow X_{t}>b_{n}\left(k_{n}\right) u^{-1 / \alpha} .
$$

The sum $\sum_{t=1}^{n(\xi)} X_{n, t}^{*}(u)$ denotes a centered tail empirical distribution function, and $X_{n, t}$ simply represents a centered $b_{n}$-exceedance process. See Davis and Resnick (1984), Beirlant, Teugels and Vynckier (1994), Hsing (1991) and Rootzén et al (1998). Both processes have been used in damage modeling in the engineering, actuarial and meteorological sciences, and asset market risk and volatility analysis. Moreover, both are key to deriving an asymptotic theory for tail index estimators and tail quantile functions: see Theorem 6.

LEMMA 2 Each $Y_{n, t}(u) \in\left\{X_{n, t}, X_{n, t}^{*}(u)\right\}$ is an $L_{r}$-Functional-Tail Array for all $r \geq 1$. In particular $\sup _{t} \sup _{u \geq 0}\left\|Y_{n, t}(u)\right\|_{r}=O\left(k_{n}^{-(1 / 2-1 / r)} n^{-1 / r}\right)=$ $O\left(n^{-a(r)}\right)$ where $a(1)>1 / 2, a(2)=1 / 2, a(r)>1 / r \forall r>2$, and $2 a(2 r)$ $>a(r)$. If $k_{n} \sim n^{\delta}, \delta \in(0,1]$, then $a(r)=1 / 2-(1-\delta)(1 / 2-1 / r)$.

Remark: $\quad$ Both properties $2 a(4)+a(2)>1$ and $2 a(2 r)>a(r)$ invoked in Assumption 1.b are satisfied for each $\left\{X_{n, t}, X_{n, t}^{*}(u)\right\}$.

The $L_{p}$-FE-NED properties (4)-(5) are particularly insightful for characterizing extremal dependence in $\left\{X_{t}\right\}$ itself if the associated Tail Array is the extremal event $X_{n, t}^{*}(u)$. Given $\Im_{t-q_{n}}^{t+q_{n}}:=\sigma\left(X_{\tau}: t-q_{n} \leq \tau \leq t+q_{n}\right)$, properties (4)-(5) applied to $X_{n, t}^{*}(u)$ reduce to

$$
\begin{align*}
k_{n}^{-1 / 2} \| P\left(x_{t}\right. & \left.<v_{n} u \mid \Im_{t-q_{n}}^{t+q_{n}}\right)-P\left(x_{t}<v_{n} u \mid \digamma_{n, t-q_{n}}^{t+q_{n}}\right) \|_{p}  \tag{9}\\
& \leq d_{n, t}(u) \times \varphi_{q_{n}}
\end{align*}
$$

$$
\begin{gather*}
k_{n}^{-1 / 2}\left\|P\left(v_{n} u_{1}<x_{t} \leq v_{n} u_{2} \mid \Im_{t-q_{n}}^{t+q_{n}}\right)-P\left(v_{n} u_{1}<x_{t} \leq v_{n} u_{2} \mid \digamma_{n, t-q_{n}}^{t+q_{n}}\right)\right\|_{p}  \tag{10}\\
\leq\left(\tilde{d}_{n, t} \times\left|u_{2}-u_{1}\right|^{1 / p}\right) \times \varphi_{q_{n}} .
\end{gather*}
$$

for all $u_{1} \leq u_{2}$. The $L_{p}$-Extremal-NED property (9) was introduced in Hill (2005b).

Remark 1: $\quad$ Property (9) implies the scaled event $\left(n / k_{n}\right)^{1 / 2} I\left(X_{t}>b_{n} u^{-1 / \alpha}\right)$ can be almost surely perfectly approximated by $\left(n / k_{n}\right)^{1 / 2} P\left(X_{t}>b_{n} u^{-1 / \alpha} \mid \digamma_{n, t-q_{n}}^{t+q_{n}}\right)$ as $n \rightarrow \infty$, given $\sqrt{n} d_{n, t}(u) q_{n}^{\lambda} \varphi_{q_{n}} \rightarrow 0$.

Remark 2: The above construction marks a fundamental distinction between canonical NED and FE-NED properties. The FE-NED properties restrict extreme events $X_{t}>b_{n} u^{-1 / \alpha}$ to be Near-Epoch-Dependent on $\left\{\digamma_{n, t}\right\}$, and $\digamma_{n, t}$ need only be induced by the extremes of some $\epsilon_{t}$. The FE-NED properties only characterize memory and heterogeneity for extremes: (9) and (10) say nothing about the event $X_{t} \leq b_{n} u^{-1 / \alpha} \rightarrow \infty$.

Remark 3: In Hill (2005b, 2006) we present a simple class of extremal processes that does not satisfy NED or $L_{p}$-weak dependence properties but does satisfy (9)-(10). Moreover, in Hill (2006) we prove that Tail Arrays like $X_{n, t}^{*}(u)$ do not satisfy key assumptions of the best extant central limit theory for NED arrays, cf. de Jong (1997).

If $\left\{X_{t}\right\}$ satisfies (9)-(10), then both tail arrays $\left\{X_{n, t}, X_{n, t}^{*}(u)\right\}$ are $L_{2}$-NED, a la Gallant and White (1988). In this sense (9)-(10) characterize a primitive tail memory property.

LEMMA 3 (Hill 2006) Let $\left\{X_{t}\right\}$ satisfy (6), (9) and (10) with coefficients $\varphi_{q_{n}}=o\left(n^{a(r)-1 / 2} \times q_{n}^{-\lambda}\right)$, and Lebesgue measurable functions $d_{n, t}(u):$ $[0,1] \rightarrow \mathbb{R}_{+}$, where $\sup _{u \in[0,1], t \geq 1} d_{n, t}(u)=O\left(n^{-a(r)}\right),\left(\int_{0}^{1} u^{-1} d_{n, t}(u)^{p} d u\right)^{1 / p}$ $=O\left(n^{-a(r)}\right)$, and $\tilde{d}_{n, t}=O\left(n^{-a(r)}\right)$. Then $\left\{X_{n, t}, X_{n, t}^{*}(u)\right\}$ are $L_{2}-N E D$ on $\left\{\digamma_{n, t}\right\}$ with common coefficients $\varphi_{q_{n}} .\left\{X_{n, t}\right\}$ has constants

$$
K \times\left(-\alpha^{-1} \int_{0}^{1} u^{-1} d_{n, t}(u)^{p} d u\right)^{1 / p}
$$

Let

$$
T_{n, t}(u) \in\left\{X_{n, t}, X_{n, t}^{*}(u)\right\}
$$

The following result is a direct consequence of Theorem 1 and Lemmas 2 and 3.

## Assumption 2

(a) $\left\{X_{t}\right\}$ satisfies (6) and is $L_{p}$-FE-NED a $l a$ (9) and (10) with coefficients $\left\{\varphi_{q_{n}}\right\}$ of size $-1 / 2$, constants $\left\{d_{n, t}(u), \tilde{d}_{n, t}\right\}=O\left(n^{-a(r)}\right)$ and $\left(\int_{0}^{\infty} d_{n, t}(u)^{p} d u\right)^{1 / p}=O\left(n^{-a(r)}\right)$. The base $\left\{\epsilon_{t}\right\}$ is either E-uniform mixing with size $-r / 2(r-1), r \geq 2$, or E-strong mixing base with size $-r /(r$ $-2), r>2$.
(b) $\left|r_{n}(\xi+\delta) / r_{n}(\xi)-\kappa_{\delta}(\xi)\right| \rightarrow 0$ for some finite $\kappa_{\delta}(\xi) \geq 1$ and each $\xi \in$ $[\underline{\xi}, 1-\delta]$ and $\{u, \delta\} \in[0,1]$, and $g_{n}=o\left(n^{\min \{[2 a(4)+a(2)-1] / 2,2 a(2 r)-a(r)\}}\right)$.

COROLLARY 4 Under Assumption 2 with $p=2, \sum_{t=1}^{n(\xi)} T_{n, t}(u) \Rightarrow T(\xi, u)$ on $D_{2}$, where $Y(\xi, u)$ is Gaussian with independent increments and covariance function $E\left[T\left(\xi_{i}, u_{i}\right) T\left(\xi_{j}, u_{j}\right)\right]$.

If $k_{n} \sim n^{\delta}$ for some $\delta \in(0,1)$ then Lemma 2 can be used to verify $\min \{[2 a(4)$ $+a(2)-1] / 2,2 a(2 r)-a(r)\}=\delta / 4$. If additionally $n(\xi)=[n \xi]$ then Corollary 4 can be greatly simplified: all we ultimately need is Assumption 2.a.

COROLLARY 5 Let Assumption 2.a hold with $p=2$, and let $n(\xi)=[n \xi]$, $k_{n} \sim n^{\delta}, \delta \in(0,1)$ and $g_{n}=o\left(n^{\delta / 4}\right)$. Then $\sum_{t=1}^{[n \xi]} T_{n, t}(u) \Rightarrow T(\xi, u)$ on $D_{2}$, where $T(\xi, \cdot)$ is Brownian motion.

4 FE-NED EXAMPLES Any $L_{p}$-NED process $X_{t}$ with tails (6) and $\lim _{x \rightarrow \infty} L(x)=c$ has the $L_{2}$-FE-NED property (9). This includes tails of the form $\bar{F}(x)=c x^{-\alpha}\left(1+d x^{-\beta}+O\left(x^{-\theta}\right)\right),(c, d) \geq 0,(\beta, \theta)>0$, and related expansions (e.g. Hall 1982, Hall and Welsh 1985). Thus, linear, conditional volatility (Davidson 2004), bilinear (Davidson 1994) and many nonlinear distributed lags (Gallant and White 1988) with iid innovations that satisfy (1) and $L(x) \rightarrow c$ are $L_{2}$-E-NED. For any slowly varying $L(x)$ in (6), (9) holds with a complicated expression for $d_{n, t}(u)$. In general, ARFIMA, FIGARCH, simple bilinear, random coefficient autoregression, and Extremal Threshold processes are $L_{2}$-FE-NED (9)-(10) if the underlying innovations are $i i d$ with tails (1). See Hill (2005b, 2006).
5. APPLICATIONS In this section we develop a functional limit theory for a tail dependence estimator, the B. Hill (1975) tail index estimator, and an intermediate tail quantile function.

### 5.1 Functional Tail Index Estimation

Let $\left\{X_{t}\right\}$ satisfy (6). We derive the functional distribution limit of the Hillestimator

$$
\hat{\alpha}_{n}^{-1}(\xi):=1 / k_{n}(\xi) \sum_{t=1}^{n(\xi)}\left(\ln X_{t} / X_{\left(\left[k_{n}(\xi)\right]+1\right)}\right)_{+}
$$

and tail quantile function $X_{\left(\left[k_{n}(\xi)\right]\right)}$ for $L_{2}$-FE-NED processes. Without introducing more notation, it is understood that $X_{\left(\left[k_{n}(\xi)\right]\right)}$ is the $\left[k_{n}(\xi)\right]^{t h}$-largest observation from the $n(\xi)$-sample $\left\{X_{1}, \ldots, X_{n(\xi)}\right\}$.

The following limit theory is the most general available for the Hill-estimator, and for any other tail estimator (that we are aware of), including those suggested by Pickands (1975), Smith (1987), and Drees et al (2004) to name a very few.

For brevity we restrict attention to

$$
n(\xi)=[n \xi]
$$

From (7) it is easily verified that

$$
k_{n}(\xi)=\left[k_{n} \xi\right]
$$

hence

$$
\left(n(\xi) / k_{n}(\xi)\right) P\left(X_{t}>b_{n(\xi)}\left(k_{n}(\xi)\right)\right) \sim\left(n / k_{n}\right) P\left(X_{t}>b_{n(\xi)}\left(k_{n}(\xi)\right)\right) \rightarrow 1
$$

logically implies $b_{n(\xi)}\left(k_{n}(\xi)\right) \sim b_{n}\left(k_{n}\right)$.
We must restrict the tail shape in order to expedite asymptotic normality. Cf. Goldie and Smith (1987), Hsing (1991) and Hill (2005b).

Assumption 3 For some positive measurable function $g: \mathbb{R}_{+} \rightarrow \mathbb{R}_{+}$

$$
\begin{equation*}
L(\lambda x) / L(x)-1=O(g(x)) \text { as } x \rightarrow \infty . \tag{11}
\end{equation*}
$$

We assume $g$ has bounded increase: there exists $0<D, z_{0}, \tau<\infty$ such that $g(\lambda z) / g(z) \leq D \lambda^{\tau}$ some for $\lambda \geq 1, z \geq z_{0}$. Assume $\tau \leq 0$. We require $\left\{k_{n}\right\}$ and $g(\cdot)$ to satisfy
(12) $\sqrt{k_{n}} g\left(b_{n}\left(k_{n}\right)\right) \rightarrow 0$.

Remark: Tails satisfying (6), (11) and (12) include the popularly assumed forms $\bar{F}(x)=c x^{-\alpha}\left(1+O\left((\ln x)^{-\theta}\right)\right)$ and $\bar{F}(x)=c x^{-\alpha}\left(1+O\left(x^{-\theta}\right)\right)$. In the latter case (12) holds only if $k_{n} / n^{2 \theta /(2 \theta+\alpha)} \rightarrow 0$. See Haeusler and Teugels (1985).

Define

$$
\begin{aligned}
& \tilde{\sigma}_{n}^{2}(\xi):=E\left(\sum_{t=1}^{[n \xi]} X_{n, t}^{*}\left(u^{1 / \sqrt{k_{n}}}\right)\right)^{2} \\
& \sigma_{n}^{2}(\xi):=E\left(k_{n}^{1 / 2}\left(\hat{\alpha}_{n}^{-1}(\xi)-\alpha^{-1}\right)\right)^{2}
\end{aligned}
$$

THEOREM 6 Let $\left\{X_{t}\right\}$ satisfy Assumption 2 with $p=2$ and Assumption 3.
Then

$$
k_{n}^{1 / 2}\left(\hat{\alpha}_{n}^{-1}(\xi)-\alpha^{-1}\right) \Rightarrow X(\xi)
$$

where $X(\xi)$ is Brownian motion with variance $\lim _{n \rightarrow \infty} \sigma_{n}(\xi)<\infty$. Moreover,

$$
k_{n}^{1 / 2}\left(\ln X_{\left(\left[k_{n} \xi\right]\right)} / b_{n}\right) \Rightarrow Y(\xi)
$$

where $Y(\xi)$ is Brownian motion of $D[\underline{\xi}, 1]$ with variance $\lim _{n \rightarrow \infty} \check{\sigma}_{n}^{2}(\xi)$ $<\infty$.

Remark 1: Hill (2005b: Theorem 6) proves a kernel variance estimator of $\sigma_{n}^{2}(1)$ is consistent for Extremal-NED processes. Extending the proof to $\sigma_{n}^{2}(\xi)$ is trivial.

Remark 2: A non-functional limit for B. Hill's estimator is immediate, cf. Theorem 5 of Hill (2005b): $k_{n}^{1 / 2}\left(\hat{\alpha}_{n}^{-1}(1)-\alpha^{-1}\right) / \sigma_{n}(1) \Rightarrow N(0,1)$ provided $\lim \inf _{n \geq 1} \sigma_{n}^{2}(1)>0$.

### 5.2 Tail Dependence

Consider two stochastic processes $\left\{X_{1, t}, X_{2, t}\right\}$ with marginal distributions $F_{i}$ with support on $[\infty, 0)$. Assume each $F_{i}$ has a regularly varying tails (6) with index $\alpha_{i}>0$.

Define

$$
Z_{i, n, t}\left(u_{i}\right):=I\left(x_{i, t} \leq v_{i, n} u_{i}\right)-E\left[I\left(x_{i, t} \leq v_{i, n} u_{i}\right)\right], i=1,2
$$

where $x_{i, t}=\bar{F}_{i}\left(X_{i, t}\right), v_{i, n}=\bar{F}_{i}\left(b_{i, n}\left(k_{i, n}\right)\right)$, and $b_{i, n}\left(k_{i, n}\right)$ and $k_{i, n}$ satisfy (7) for each $i$. In most applications $u_{i}=1$. Let $n(\xi)=[n \xi]$. We obtain from (6)-(7) and some sequence $k_{i, n}$

$$
\begin{aligned}
& \lim _{n \rightarrow \infty}\left(n / k_{i, n}\right) E\left[Z_{i, n, t}^{2}\left(u_{i}\right)\right] \\
&=\lim _{n \rightarrow \infty}\left(n / k_{i, n}\right)\left[P\left(X_{i, t}>b_{i, n}\left(k_{i, n}\right) u_{i}^{-1 / \alpha_{i}}\right)-P\left(X_{i, t}>b_{i, n}\left(k_{i, n}\right) u_{i}^{-1 / \alpha_{i}}\right)^{2}\right] \\
&=u_{i}
\end{aligned}
$$

This suggests a simple functional tail dependence coefficient:

$$
\begin{aligned}
& \rho_{\alpha, n}(h, u)= \frac{E\left[Z_{1, n, t}\left(u_{1}\right) \times Z_{2, n, t-h}\left(u_{2}\right)\right]}{\sqrt{u_{1} k_{1, n} / n} \sqrt{u_{2} k_{2, n} / n}} \\
&=\left(n / k_{n}(u)\right) \times\left[P\left(X_{1, t}>b_{1, n}\left(k_{1, n}\right) \tilde{u}_{1}, X_{2, t-h}>b_{2, n}\left(k_{2, n}\right) \tilde{u}_{2}\right)\right. \\
&\left.\quad-P\left(X_{1, t}>b_{1, n}\left(k_{1, n}\right) \tilde{u}_{1}\right) P\left(X_{2, t-h}>b_{2, n}\left(k_{2, n}\right) \tilde{u}_{2}\right)\right]
\end{aligned}
$$

where

$$
k_{n}(u):=\left(k_{1, n} u_{1} k_{1, n} u_{2}\right)^{1 / 2} \quad \text { and } \quad \tilde{u}_{i}=u_{i}^{-1 / \alpha_{i}} .
$$

If $\lim _{n \rightarrow \infty} \sup _{u \in[0,1]}\left|\rho_{\alpha, n}(h, u)\right|=0$ then $\left\{X_{1, t}, X_{2, t}\right\}$ are asymptotically extremalindependent at displacement $h \geq 0$.

A natural non-parametric estimator of the tail dependence coefficient for an arbitrary $n(\xi)$-subsample is

$$
\hat{\rho}_{\alpha, n}(h, \xi, u):=1 / k_{n}(u) \sum_{t=1}^{n(\xi)}\left[Z_{1, n, t}\left(u_{1}\right) \times Z_{2, n, t-h}\left(u_{2}\right)\right] .
$$

In order to exploit Correlation 4 we must show the centered product

$$
Z Z_{n, t}(u, h):=\frac{1}{\sqrt{k_{n}(u)}}\left\{Z_{1, n, t}\left(u_{1}\right) Z_{2, n, t-h}\left(u_{2}\right)-E\left[Z_{1, n, t}\left(u_{1}\right) Z_{2, n, t-h}\left(u_{2}\right)\right]\right\}
$$

is $L_{2}$-FE-NED. We do this by assuming each $\left\{X_{i, t}\right\}$ is $L_{4}$-FE-NED.
For arbitrary $\lambda \in \mathbb{R}^{h}, h \geq 1$ write

$$
Z Z_{n, t}(\lambda, u, h):=\sum_{i=1}^{h} \lambda_{i} Z Z_{n, t}(u, i)
$$

LEMMA 7 (Hill, 2006) Let $\left\{X_{1, t}, X_{2, t}\right\}$ satisfy the $L_{p}$-FE-NED property (9)(10), with $p=4$. Then $\left\{Z Z_{n, t}(\lambda, u, h)\right\}$ is $L_{2}-N E D$ on $\left\{\digamma_{n, t}\right\}$ with constants $d d_{n, t}(\lambda, u)=O\left(n^{-a(r)}\right)$ and coefficients $\varphi \varphi_{q_{n}}=o\left(n^{a(r)-1 / 2}\right.$ $\left.\times q_{n}^{-1 / 2}\right)$. Moreover, $\left\{Z Z_{n, t}(\lambda, u, h), \digamma_{n, t}\right\}$ forms an $L_{2}$-mixingale sequence with size $-1 / 2$ and constants $c c_{n, t}(\lambda, u)=O\left(n^{-1 / 2}\right)$. Finally, $E\left(\sum_{t=1}^{n} Z Z_{n, t}(\lambda, h, u)\right)^{2}=O(1)$.

Lemmas 2,3 and 7 imply Theorem 1 holds for $\left\{Z Z_{n, t}(\lambda, u, h)\right\}$ for any $\lambda \in$ $\mathbb{R}^{h}$. Along with a Cramér-Wold device this proves the following claim. Write $\rho_{\alpha}^{(h)}(\xi, u)=\left[\rho_{\alpha}(1, \xi, u), \ldots, \rho_{\alpha}(h, \xi, u)\right]^{\prime}$, etc.

THEOREM 8 Let $\left\{X_{1, t}, X_{2, t}\right\}$ satisfy Assumption 2 with $p=4$, coefficients $\left\{\varphi_{i, q_{n}}\right\}$ and constants $\left\{d_{i, n, t}(u), \tilde{d}_{i, n, t}\right\}, i=1,2$. Then

$$
\sqrt{k_{n}(u)}\left(\hat{\rho}_{\alpha, n}^{(h)}(\xi, u)-\rho_{\alpha}^{(h)}(\xi, u)\right) \Rightarrow X(\xi, u)
$$

where $X(\xi, u)$ is a Gaussian h-vector with independent scalar increments, covariance matrix function $E\left[X\left(\xi_{i}, u_{i}\right) X\left(\xi_{j}, u_{j}\right)^{\prime}\right] \in \mathbb{R}^{h \times h}$, and variances $E\left[X_{i}(\xi, u)^{2}\right]<\infty$.

Remark 1: The above result trivially applies to the serial extremal dependence case for any $h \geq 1$. Thus, Theorem 8 is the most general of its kind in the tail dependence literature.

Remark 2: In order to make $\hat{\rho}_{\alpha, n}^{(h)}(\xi, u)$ operational, the tail quantile estimator $X_{i,\left(\left[k_{i, n} \xi\right]+1\right)}$ will have to be used as an estimate of the approximate $k_{i, n} / n^{t h}$-quantile $b_{i, n}\left(k_{i, n}\right)$. Theorem 6 implies $X_{\left(\left[k_{n} \xi\right]\right)}=b_{n}+O_{p}\left(1 / \sqrt{k_{n}}\right)$. We are currently investigating this issue in related work.

## Appendix 1: Proofs of Main Results

Proof of Theorem 1. In Step 1 we prove $X_{n}(\xi, u) \Rightarrow X(\xi, u)$ by showing conditions (a)-(f) of Lemma A. 1 in Appendix 2 hold under the maintained assumptions. In Step 2 we prove the increments of the limiting process $X(\xi, u)$
are independent.
Step 1 (weak convergence) By Lemma A. $4\left\{X_{n, t}(u), \digamma_{n, t}\right\}$ forms an $L_{2^{-}}$ mixingale sequence with constants $c_{n, t}(u), \sup _{u \in[0,1], t \geq 1} c_{n, t}(u)=O\left(n^{-1 / 2}\right)$, and coefficients $\psi_{q_{n}}=o\left(q_{n}^{-1 / 2}\right)$.

Define

$$
\tilde{F}_{n, i}:=\bigcup_{\tau \leq i g_{n}} \digamma_{n, \tau}, \quad \digamma_{n, s}^{t}:=\sigma\left(E_{n, \tau}: 1 \leq s \leq \tau \leq t \leq n\right)
$$

Condition (a): Using a standard bound for $L_{2}$-mixingales with size $-1 / 2$, cf. McLeish (1975),

$$
\begin{aligned}
E\left(\sum_{i=1}^{r_{n}}\right. & \left.\sum_{t=(i-1) g_{n}+1}^{(i-1) g_{n}+l_{n}} X_{n, t}(u)\right)^{2} \\
& =O\left(\sum_{i=1}^{r_{n}} \sum_{t=(i-1) g_{n}+1}^{(i-1) g_{n}+l_{n}} c_{n, t}^{2}(u)\right) \\
& =O\left(r_{n} l_{n} n^{-1}\right)=O\left(l_{n} g_{n}^{-1}\right)=o(1)
\end{aligned}
$$

hence $\sum_{i=1}^{r_{n}} \sum_{t=(i-1) g_{n}+1}^{(i-1) g_{n}+l_{n}} X_{n, t}(u)=\sum_{i=1}^{r_{n}} Z_{n, i}(u) \rightarrow 0$ by Chebyshev's inequality.
Condition (b): Define the index sets

$$
\begin{aligned}
& A_{i}(t):=\left\{t:(i-1) g_{n}+l_{n}+1 \leq t \leq i g_{n}\right\} \\
& A_{n, t}=\cup_{i=1}^{r_{n}} A_{i}(t)
\end{aligned}
$$

Analogous to de Jong's (1997: A.7-A.12) argument, because $\left\{X_{n, t}(u), \digamma_{n, t}\right\}$ forms an $L_{2}$-mixingale sequence, for $t \in A_{n, t}$ it can be shown $\left\{E\left[X_{n, t}(u) \mid \tilde{F}_{n, i-1}\right], \digamma_{n, t}\right\}$ forms an $L_{2}$-mixingale sequence with constants $c_{n, t}(u) \psi_{l_{n}}^{\eta}$ and coefficients $\psi_{l_{n}}^{1-\eta}$ $=o\left(l_{n}^{-1 / 2}\right)$ for some sufficiently tiny $\eta>0$. McLeish's (1975) bound now gives

$$
\begin{aligned}
E\left(\sum_{i=1}^{r_{n}} E\left[Z_{n, i}(u) \mid \tilde{F}_{n, i-1}\right]\right)^{2}=O & \left(\sum_{i=1}^{r_{n}} \sum_{t=(i-1) g_{n}+l_{n}+1}^{i g_{n}} c_{n, t}^{2}(u) \psi_{l_{n}}^{2 \eta}\right) \\
& =O\left(r_{n} g_{n} n^{-1} l_{n}^{-\eta}\right)=O\left(l_{n}^{-\eta}\right)=o(1)
\end{aligned}
$$

Condition (c): The proof mimics (b).
Condition (d): Recall $W_{n, i}:=E\left[Z_{n, i} \mid \tilde{F}_{n, i}\right]-E\left[Z_{n, i} \mid \tilde{F}_{n, i-1}\right]$, write

$$
Z_{n, i}(j)=Z_{n, i}\left(\xi_{j}, u_{j}\right), \quad W_{n, i}(j)=W_{n, i}\left(\xi_{j}, u_{j}\right)
$$

and note

$$
\sum_{i=1}^{r_{n}\left(\xi_{k}\right)} \tilde{W}_{n, i}^{2}(\pi)=\sum_{l=1}^{k} \sum_{i=r_{n}\left(\xi_{l-1}\right)+1}^{r_{n}\left(\xi_{l}\right)}\left(\sum_{j=l}^{k} \pi_{j} W_{n, i}(j)\right)^{2}, \pi^{\prime} \pi=1
$$

Analogous to de Jong (1997: A.13-A.17) we obtain

$$
\begin{aligned}
\sup _{\pi^{\prime} \pi=1} \| & \sum_{l=1}^{k} \sum_{i=r_{n}\left(\xi_{l-1}\right)+1}^{r_{n}\left(\xi_{l}\right)}\left(\sum_{j=l}^{k} \pi_{j} Z_{n, i}\left(u_{j}\right)\right)^{2}-\sum_{i=1}^{r_{n}\left(\xi_{k}\right)} \tilde{W}_{n, i}^{2}(\pi) \|_{1} \\
& =\sup _{\pi^{\prime} \pi=1} \| \sum_{l=1}^{k} \sum_{i=r_{n}\left(\xi_{l-1}\right)+1}^{r_{n}\left(\xi_{l}\right)}\left[\left(\sum_{j=l}^{k} \pi_{j} Z_{n, i}\left(u_{j}\right)\right)^{2}-\left(\sum_{j=l}^{k} \pi_{j} W_{n, i}\left(u_{j}\right)\right)^{2}\right]_{1} \\
& \leq K \sum_{l=1}^{k} \sum_{j_{1}, j_{2}=l}^{k} \sum_{i=r_{n}\left(\xi_{l-1}\right)+1}^{r_{n}\left(\xi_{l}\right)}\left\|\left(Z_{n, i}\left(u_{j_{1}}\right)-W_{n, i}\left(u_{j_{1}}\right)\right)\right\|_{2} \times\left\|Z_{n, i}\left(u_{j_{2}}\right)\right\|_{2} \\
= & O\left(\sum_{l=1}^{k} \sum_{i=r_{n}\left(\xi_{l-1}\right)+1}^{r_{n}\left(\xi_{l}\right)}\left(\sum_{t \in A_{i}(t)} c_{n, t}^{2} \psi_{l_{n}}^{2 \eta}\right)^{1 / 2}\left(\sum_{t \in A_{i}(t)} c_{n, t}^{2}\right)^{1 / 2}\right) \\
= & O\left(\sum_{l=1}^{k} r_{n}\left(\xi_{l}\right) \times\left[g_{n} n^{-1} l_{n}^{-\eta}\right]^{1 / 2} \times\left[g_{n} n^{-1}\right]^{1 / 2}\right) \\
= & O\left(l_{n}^{-\eta / 2}\right)=o(1)
\end{aligned}
$$

Along with Lemma A. $4 \sup _{\pi^{\prime} \pi=1}\left|\sum_{i=1}^{r_{n}\left(\xi_{k}\right)} \tilde{W}_{n, i}^{2}(\pi)-1\right| \rightarrow 0$.
Condition (e): For any $\{\xi,(u, \delta)\} \in[\underline{\xi}, 1] \times[0,1]^{2}$ and some integer sequence $\left\{r_{n}^{*}(\xi)\right\}$ satisfying $\forall n \geq 1$

$$
0 \leq\left[r_{n}^{*}(\xi) \delta\right] \leq r_{n}(\xi+\delta)-r_{n}(\xi)
$$

we have

$$
\begin{align*}
&\left\|\sum_{i=1}^{\left[r_{n}^{*}(\xi) \delta\right]} W_{n, i}(u)\right\|_{2}  \tag{13}\\
& \leq\left\|\sum_{i=1}^{\left[r_{n}^{*}(\xi) \delta\right]} \sum_{t=(i-1) g_{n}+l_{n}+1}^{i g_{n}} X_{n, t}(u)\right\|_{2} \\
&+\left\|\sum_{i=1}^{\left[r_{n}^{*}(\xi) \delta\right]} \sum_{t=(i-1) g_{n}+l_{n}+1}^{i g_{n}}\left(X_{n, t}(u)-E\left[X_{n, t}(u) \mid \tilde{F}_{n, i}\right]\right)\right\|_{2} \\
&+\left\|\sum_{i=1}^{\left[r_{n}^{*}(\xi) \delta\right]} \sum_{t=(i-1) g_{n}+l_{n}+1}^{i g_{n}} E\left[X_{n, t}(u) \mid \tilde{F}_{n, i-1}\right]\right\|_{2}
\end{align*}
$$

Under the maintained assumptions $\left\{X_{n, t}(u), \digamma_{n, t}\right\}$ forms an $L_{2}$-mixingale sequence with size $-1 / 2$ and constants $c_{n, t}(u)=O\left(n^{-1 / 2}\right)$. Similarly, for each $t \in A_{n, t},\left\{E\left[X_{n, t}(u) \mid \tilde{F}_{n, i-1}\right], \digamma_{n, t}\right\}$ and $\left\{X_{n, t}(u)-E\left[X_{n, t}(u) \mid \tilde{F}_{n, i}\right], \digamma_{n, t}\right\}$ form $L_{2}$-mixingale sequences with size $-1 / 2$ and constants $\left\{c_{n, t}(u) \psi_{n, l_{n}}^{\eta}\right\}$ for some tiny $\eta>0$ : see de Jong (1997: p. 360-361). Applying McLeish's (1975) bound
to each right-hand-side term of (13), and noting $\psi_{n, l_{n}}^{\eta}=O\left(l_{n}^{-\eta / 2}\right)=o(1)$,

$$
\begin{aligned}
E\left(\sum_{i=1}^{\left[r_{n}^{*}(\xi) \delta\right]} W_{n, i}(u)\right)^{2} & =O\left(\sum_{i=1}^{\left[r_{n}^{*}(\xi) \delta\right]} \sum_{t=(i-1) g_{n}+l_{n}+1}^{i g_{n}} c_{n, t}^{2}(u)\right) \\
& =\delta \times O\left(r_{n}^{*}(\xi) g_{n} / n\right)
\end{aligned}
$$

By Assumption 1.b there exists for each $\{\xi, \delta\} \in[\underline{\xi}, 1] \times[0,1]$ a finite $\kappa(\xi, \delta) \geq$ 1 satisfying

$$
\begin{aligned}
{\left[r_{n}^{*}(\xi) \delta\right] g_{n} / n \leq\left[r_{n}^{*}(\xi) \delta\right] g_{n} / n(\xi) \leq } & \left(r_{n}(\xi+\delta) / r_{n}(\xi)-1\right) \times(1+o(1)) \\
& \rightarrow \kappa(\xi, \delta)-1<\infty
\end{aligned}
$$

But if $\left[r_{n}^{*}(\xi) \delta\right] g_{n} / n$ is bounded then so is $r_{n}^{*}(\xi) g_{n} / n$. Hence, for sufficiently large $n$ and some $\kappa \geq 1$

$$
\sum_{i=1}^{\left[r_{n}^{*}(\xi) \delta\right]} E\left(W_{n, i}(u)\right)^{2} \leq \delta \times \kappa
$$

Condition (f): $\quad$ Define $Y_{n, t}\left(u_{1}, u_{2}\right):=X_{n, t}\left(u_{1}\right)-X_{n, t}\left(u_{2}\right)$. Mimicking (13) and the subsequent logic and, exploiting the fact that linear functions of mixingales are mixingales, we deduce

$$
\begin{align*}
\| W_{n}\left(\xi, u_{1}\right)- & W_{n}\left(\xi, u_{2}\right) \|_{2}  \tag{14}\\
\leq & \left\|\sum_{i=1}^{r_{n}(\xi)} \sum_{t=(i-1) g_{n}+l_{n}+1}^{i g_{n}} Y_{n, t}\left(u_{1}, u_{2}\right)\right\|_{2} \\
& +\left\|\sum_{i=1}^{r_{n}(\xi)} \sum_{t=(i-1) g_{n}+l_{n}+1}^{i g_{n}}\left(Y_{n, t}\left(u_{1}, u_{2}\right)-E\left[Y_{n, t}\left(u_{1}, u_{2}\right) \mid \tilde{F}_{n, i}\right]\right)\right\|_{2} \\
& \quad+\left\|\sum_{i=1}^{r_{n}(\xi)} \sum_{t=(i-1) g_{n}+l_{n}+1}^{i g_{n}} E\left[Y_{n, t}\left(u_{1}, u_{2}\right) \mid \tilde{F}_{n, i-1}\right]\right\|_{2} \\
= & O\left(\sum_{i=1}^{r_{n}(\xi)} \sum_{t=(i-1) g_{n}+l_{n}+1}^{i g_{n}} \tilde{c}_{n, t}^{2} \times\left|u_{1}-u_{2}\right|^{1 / 2}\right) \\
= & \left|u_{1}-u_{2}\right|^{1 / 2} \times O\left(r_{n}(\xi) g_{n} / n\right) \leq K \times\left|u_{1}-u_{2}\right|^{1 / 2}
\end{align*}
$$

## Step 2 (increments)

For any points $0<\xi_{k}<\xi_{l}<1$ and $0<\left\{u_{k}, u_{l}\right\}<1$ we need only show

$$
E\left(X_{n}\left(\xi_{k}, u_{k}\right)-X_{n}\left(\xi_{k-1}, u_{k-1}\right)\right)\left(X_{n}\left(\xi_{l}, u_{l}\right)-X_{n}\left(\xi_{l-1}, u_{l-1}\right)\right)=o_{p}(1)
$$

Write

$$
\begin{aligned}
X_{n}\left(\xi_{k}\right. & \left., u_{k}\right)-X_{n}\left(\xi_{k-1}, u_{k-1}\right) \\
& =\left[X_{n}\left(\xi_{k}, u_{k}\right)-X_{n}\left(\xi_{k-1}, u_{k}\right)\right]+\left[X_{n}\left(\xi_{k-1}, u_{k}\right)-X_{n}\left(\xi_{k-1}, u_{k-1}\right)\right] \\
& =A_{n, k}+B_{n, k}
\end{aligned}
$$

Analogous to de Jong and Davidson (2000: pp. 635-636), by exploiting MCleish's (1975) bound for $L_{2}$-mixingales of size $-1 / 2$ and the assumption $\sup _{u \in[0,1], t \geq 1} c_{n, t}(u)$ $=O\left(n^{-1 / 2}\right)$, for arbitrary $\delta \in[0,1]$ we obtain

$$
\begin{aligned}
\left|E\left[A_{n, k} A_{n, l}\right]\right| \leq & \left\|\sum_{t=n\left(\xi_{k-1}\right)+1}^{n\left(\xi_{k}\right)} X_{n, s}\left(u_{k}\right)\right\|_{2}\left\|\sum_{t=n\left(\xi_{l-1}\right)+1}^{n\left(\xi_{l-1}+\delta\right)} X_{n, t}\left(u_{l}\right)\right\|_{2} \\
& +\sum_{t, s=1}^{n(1)} E\left|X_{n, t}\left(u_{k}\right) X_{n, s}\left(u_{l}\right)\right| I\left(|s-t| \geq n\left(\xi_{l-1}+\delta\right)-n\left(\xi_{k}\right)\right) \\
= & O\left(\sup _{0<\xi_{i}<1}\left[\left(n\left(\xi_{i}\right)-n\left(\xi_{i-1}\right)\right) / n\right]\right)+o_{p}(1)=o_{p}(1)
\end{aligned}
$$

The last line follows from Lemma A. 3 of de Jong and Davidson (2000), and the assumptions $n(\xi)-n\left(\xi^{\prime}\right) \rightarrow \infty \forall \xi>\xi^{\prime}$ and $n(1) \leq n$.

Next, for arbitrary $\delta>0$

$$
\begin{aligned}
&\left|E\left[A_{n, k} B_{n, l}\right]\right| \\
& \leq\left\|\sum_{t=n\left(\xi_{k-1}\right)+1}^{n\left(\xi_{k-1}+2 \delta\right)} X_{n, t}\left(u_{k}\right)\right\|_{2}\| \|_{t=1}^{n\left(\xi_{l-1}\right)}\left(X_{n, t}\left(u_{l}\right)-X_{n, t}\left(u_{l-1}\right)\right) \|_{2} \\
&+\left\|\sum_{t=n\left(\xi_{k-1}+2 \delta\right)+1}^{n\left(\xi_{k}\right)} X_{n, t}\left(u_{k}\right)\right\|_{2}\left\|_{t=n\left(\xi_{k-1}+\delta\right)+1}^{n\left(\xi_{l-1}\right)}\left(X_{n, t}\left(u_{l}\right)-X_{n, t}\left(u_{l-1}\right)\right)\right\|_{2} \\
&+\sum_{s, t=1}^{n(1)} E\left[\left|X_{n, t}\left(u_{k}\right)\left(X_{n, s}\left(u_{l}\right)-X_{n, s}\left(u_{l-1}\right)\right)\right|\right. \\
&=\left.O I\left(|s-t| \geq n\left(\xi_{k-1}+2 \delta\right)-n\left(\xi_{k-1}+\delta\right)\right)\right] \\
&\left.\left.\left.\left.\left.\sum_{t=n\left(\xi_{k-1}\right)+1}^{n\left(\xi_{k-1}+2 \delta\right)} c_{n, t}^{2}\left(u_{k}\right)\right)^{1 / 2}\left(\sum_{t=1}^{n\left(\xi_{l-1}\right)} \tilde{c}_{n, t}^{2}\right)^{1 / 2}\right)\right)^{n\left(\xi_{l-1}\right)} \tilde{c}_{n, t}^{2}\right)^{1 / 2}\right)+o_{p}(1) \\
&+O\left(\left(\sum_{t=n\left(\xi_{k-1}+2 \delta\right)+1}^{n\left(\xi_{k}\right)} c_{n, t}^{2}\left(u_{k}\right)\right)^{1 / 2}(1)\right. \\
& t\left(\xi_{t=n\left(\xi_{k-1}+\delta\right)+1}^{n\left(\xi_{l}\right)}\right.
\end{aligned}
$$

because $\sup _{u \in[0,1], t \geq 1} c_{n, t}(u)$ and $\sup _{t \geq 1} \tilde{c}_{n, t}$ are $O\left(n^{-1 / 2}\right), 0<\xi_{k}<\xi_{l}<1$ and $n(1) \leq n$.

Finally, because $0<\xi_{k}<\xi_{l}<1$ and $n\left(\xi_{k}\right)<n\left(\xi_{l}\right)<n$,

$$
\begin{aligned}
&\left|E\left[B_{n, k} B_{n, l}\right]\right| \leq\left\|\sum_{t=1}^{n\left(\xi_{k-1}\right)}\left(X_{n, s}\left(u_{k}\right)-X_{n, s}\left(u_{k-1}\right)\right)\right\|_{2} \\
& \times\left\|\sum_{s=1}^{n\left(\xi_{l-1}\right)}\left(X_{n, s}\left(u_{l}\right)-X_{n, s}\left(u_{l-1}\right)\right)\right\|_{2} \\
&= O\left(\left(\sum_{t=1}^{n\left(\xi_{k-1}\right)} \tilde{c}_{n, t}^{2}\right)^{1 / 2}\left(\sum_{t=1}^{n\left(\xi_{l-1}\right)} \tilde{c}_{n, t}^{2}\right)^{1 / 2}\right) \\
&= O\left(\left(n\left(\xi_{k-1}\right) / n\right)^{1 / 2}\left(n\left(\xi_{l-1}\right) / n\right)^{1 / 2}\right)=o(1)
\end{aligned}
$$

Proof of Lemma 2. From (6) and (7), $\forall u \in[0,1]$
(15) $\bar{F}\left(b_{n}\right) u=\bar{F}\left(u^{-1 / \alpha} b_{n}\right) \times L\left(b_{n}\right) / L\left(u^{-1 / \alpha} b_{n}\right)$
where $u^{-1 / \alpha} \geq 1$ and $L\left(b_{n}\right) / L\left(u^{-1 / \alpha} b_{n}\right) \rightarrow 1$ by the slow variation property. Hence, for any $r \geq 1$ and $u \in[0,1]$

$$
\begin{aligned}
& \lim _{n \rightarrow \infty}\left(n / k_{n}\right)^{1 / r} k_{n}^{1 / 2}\left\|X_{n, t}^{*}(u)\right\|_{r} \\
& \quad \leq 2 \lim _{n \rightarrow \infty}\left[\left(n / k_{n}\right) P\left(\bar{F}\left(X_{t}\right)<\bar{F}\left(b_{n}\right) u\right)\right]^{1 / r} \\
& \quad=2 \lim _{n \rightarrow \infty}\left[\left(n / k_{n}\right) P\left(\bar{F}\left(X_{t}\right)<\bar{F}\left(b_{n} u^{-1 / \alpha}\right)\right)\right]^{1 / r} \\
& \quad=2 \lim _{n \rightarrow \infty}\left[\left(n / k_{n}\right) P\left(X_{t}>b_{n} u^{-1 / \alpha}\right)\right]^{1 / r} \\
& \quad=2 \lim _{n \rightarrow \infty}\left[\left(n / k_{n}\right) P\left(X_{t}>b_{n}\right) \frac{P\left(X_{t}>b_{n} u^{-1 / \alpha}\right)}{P\left(X_{t}>b_{n}\right)}\right]^{1 / r} \\
& \quad=2 u^{1 / r}<\infty
\end{aligned}
$$

Similarly, arguments in Hsing (1991: p. 1554) imply

$$
\begin{aligned}
& \lim _{n \rightarrow \infty}\left(n / k_{n}\right)^{1 / r} k_{n}^{1 / 2}\left\|X_{n, t}\right\|_{r} \\
& \quad \leq 2 \lim _{n \rightarrow \infty}(n / m)^{1 / r}\left\|\left(\ln X_{t} / b_{n}\right)_{+}\right\|_{r}=2\left(\int_{0}^{\infty} e^{-\alpha y^{1 / r}} d y\right)^{1 / r}<\infty
\end{aligned}
$$

Therefore $X_{n, t}$ and $X_{n, t}^{*}(u)$ satisfy

$$
\begin{equation*}
\left\{\left\|X_{n, t}\right\|_{r},\left\|X_{n, t}^{*}(u)\right\|_{r}\right\}=O\left(k_{n}^{-(1 / 2-1 / r)} n^{-1 / r}\right) \tag{16}
\end{equation*}
$$

As long as $k_{n} \rightarrow \infty$ as $n \rightarrow \infty$, then trivially $k_{n}^{-(1 / 2-1)} n^{-1 / 2}>n^{-1 / 2}$, $k_{n}^{-(1 / 2-1 / 2)} n^{-1 / 2}=n^{-1 / 2}$, and $k_{n}^{-(1 / 2-1 / r)} n^{-1 / r}<n^{-1 / r} \forall r>2$. Hence for
some $a(r)$ where $a(1)>1 / 2, a(2)=1 / 2$, and $a(r)>1 / r \forall r>2$, each $\left\{\left\|X_{n, t}\right\|_{r},\left\|X_{n, t}^{*}(u)\right\|_{r}\right\}$ $=O\left(n^{-a(r)}\right)$. Similarly,

$$
\begin{aligned}
O\left(n^{-2 a(2 r)}\right) & =O\left(k_{n}^{-(1 / 2-1 / 2 r)} n^{-1 / 2 r}\right)^{2}=O\left(k_{n}^{-(1-1 / r)} n^{-1 / r}\right) \\
& =O\left(k_{n}^{-(1 / 2-1 / r)} n^{-1 / r}\right) k_{n}^{-1 / 2}=O\left(k_{n}^{-1 / 2} n^{-a(r)}\right) \leq O\left(n^{-a(r)}\right)
\end{aligned}
$$

and $O\left(n^{-2 a(4)}\right)=k_{n}^{-1 / 2} n^{-1 / 2}$. Hence $2 a(2 r)>a(r)$ and $2 a(4)+a(2)>1 / 2$.
If $k_{n} \sim n^{\delta}, \delta \in(0,1]$, then (16) implies $a(r)=1 / 2-(1-\delta)(1 / 2-1 / r)$.

## Proof of Theorem 6.

Step $1\left(\hat{\alpha}_{n}^{-1}(\xi)\right): \quad$ By Lemma A. 7 for arbitrary $u \in[0,1]$

$$
k_{n}^{1 / 2}\left(\hat{\alpha}_{n}^{-1}(\xi)-\alpha^{-1}\right)=\sum_{t=1}^{[n \xi]}\left(X_{n, t}-\alpha^{-1} X_{n, t}^{*}\left(u^{k_{n}^{-1 / 2}}\right)\right)+o_{p}(1)
$$

where $\left\{X_{n, t}, X_{n, t}^{*}(\cdot)\right\}$ are defined in (8). Define

$$
\check{\sigma}_{n}^{2}(\xi):=E\left(\sum_{t=1}^{[n \xi]}\left(X_{n, t}-\alpha^{-1} X_{n, t}^{*}\left(u^{k_{n}^{-1 / 2}}\right)\right)\right)^{2}
$$

By Lemma $4\left\{X_{n, t}, X_{n, t}^{*}(u)\right\}$ are $L_{2}$-FE-NED with constants $K\left(-\alpha^{-1} \int_{0}^{1} u^{-1} d_{n, t}(u)^{2} d u\right)^{1 / 2}$ $=O\left(n^{-a(r)}\right)$ and $d_{n, t}(u)=O\left(n^{-a(r)}\right)$ respectively, and common coefficients $\varphi_{q_{n}}=o\left(n^{a(r)-1 / 2} \times q_{n}^{-\lambda}\right)$. An argument identical to Lemma 3 of Hill (2005b) shows $\left\{X_{n, t}, X_{n, t}^{*}(u)\right\}$ are $L_{2}$-mixingales with size $-1 / 2$ and constants of order $O\left(n^{-1 / 2}\right)$, hence $\check{\sigma}_{n}^{2}(\xi)=O(1)$ follows from McLeish's (1975a) bounds.

The continuous mapping theorem and Corollary 4 now imply

$$
\sum_{t=1}^{[n \xi]}\left(X_{n, t}-\alpha^{-1} X_{n, t}^{*}\left(u^{k_{n}^{-1 / 2}}\right)\right) \Rightarrow X(\xi)
$$

for some Gaussian element $X(\xi)$ of $D[\underline{\xi}, 1]$ with variance $\lim _{n \rightarrow \infty} \check{\sigma}_{n}(\xi)<\infty$. Therefore, $\left|\sigma_{n}^{2}(\xi)-\check{\sigma}_{n}^{2}(\xi)\right| \rightarrow 0$ implying $\sigma_{n}^{2}(\xi)=O(1)$.
Step $2\left(X_{\left(\left[\xi k_{n}\right]\right)}\right)$ : By Lemma A. $8 \sum_{t=1}^{[n \xi]} X_{n, t}^{*}\left(u / \sqrt{k_{n}}\right) \Rightarrow Y(\xi)$ for some Gaussian element $Y(\xi)$ of $D[\underline{\xi}, 1]$ with variance

$$
\lim _{n \rightarrow \infty} \tilde{\sigma}_{n}^{2}(\xi)=\lim _{n \rightarrow \infty} E\left(\sum_{t=1}^{[n \xi]} X_{n, t}^{*}\left(u^{k_{n}^{-1 / 2}}\right)\right)^{2}<\infty
$$

The limit $\lim _{n \rightarrow \infty} \tilde{\sigma}_{n}^{2}(\xi)<\infty$ follows from Step 1. An argument identical to Theorem 2.2 of Hsing (1991) now completes the proof: $\sum_{t=1}^{[n \xi]} X_{n, t}^{*}\left(u^{k_{n}^{-1 / 2}}\right) \Rightarrow$ $Y(\xi)$ implies $k_{n}^{1 / 2} \ln X_{\left(\left[k_{n} \xi\right]\right)} / b_{n} \Rightarrow Y(\xi)$.

## Appendix 2: Supporting Lemmata

We require the following notation. Let $\left\{\digamma_{n, t}\right\}$ be an arbitrary array of $\sigma$ fields and define

$$
\tilde{F}_{n, i}:=\bigcup_{\tau \leq i g_{n}} \digamma_{n, \tau}
$$

For any point $\{\xi, u\}$ and $\pi \in \mathbb{R}^{k}, \pi^{\prime} \pi=1$, write

$$
\begin{aligned}
& W_{n}(\xi, u):=\sum_{i=1}^{r_{n}(\xi)} W_{n, i}(u)=\sum_{i=1}^{r_{n}(\xi)}\left(E\left[Z_{n, i} \mid \tilde{F}_{n, i}\right]-E\left[Z_{n, i} \mid \tilde{F}_{n, i-1}\right]\right) \\
& \tilde{W}_{n, i}(\pi):=\sum_{j=l}^{k} \pi_{j} W_{n, i}\left(u_{j}\right), i=r_{n}\left(\xi_{l-1}\right)+1 \ldots r_{n}\left(\xi_{l}\right), l=1 \ldots k
\end{aligned}
$$

LEMMA A. 1 Let $\left\{X_{n, t}(u)\right\}$ be an $L_{r}$-Functional Tail Array with $r^{\text {th }}$-moment index $a(r), 2 a(4)+a(2)>1$. Let $g_{n}=o\left(n^{[2 a(4)+a(2)-1] / 2}\right)$. If
(a) $\quad \sum_{i=1}^{r_{n}(\xi)} Z_{n, i}(u) \rightarrow 0, \forall j=1 \ldots k$
(b) $\quad \sum_{i=1}^{r_{n}(\xi)} E\left[Z_{n, i}(u) \mid \tilde{F}_{n, i-1}(\xi)\right] \rightarrow 0$,
(c) $\quad \sum_{i=1}^{r_{n}(\xi)}\left(Z_{n, i}(u)-E\left[Z_{n, i}(u) \mid \tilde{F}_{n, i}\right]\right) \rightarrow 0$,
(d) $\quad \sup _{\pi^{\prime} \pi=1}\left|\sum_{i=1}^{r_{n}\left(\xi_{k}\right)} \tilde{W}_{n, i}^{2}(\pi)-1\right| \rightarrow 0$,
(e) $\quad \sum_{i=1}^{\left[r_{n}^{*}(\xi) \delta\right]} E\left(W_{n, i}(u)\right)^{2} \leq \delta \times \kappa, \quad \forall \delta \in[0,1]$,
for some some $\kappa \geq 1$ and sequence $\left\{r_{n}^{*}(\xi)\right\}$ satisfying $0 \leq\left[\delta r_{n}^{*}(\xi)\right] \leq r_{n}(\xi$ $+\delta)-r_{n}(\xi)$, and $\forall u_{1}, u_{2} \in[0,1]$

$$
\text { (f) } \sup _{\xi \in[\xi, 1]}\left\|W_{n}\left(\xi, u_{1}\right)-W_{n}\left(\xi, u_{2}\right)\right\|_{2} \leq K\left|u_{2}-u_{1}\right|^{1 / 2}
$$

then $X_{n}(\xi, u) \Rightarrow X(\xi, u)$ on $D_{2}$ where $X(\xi, u)$ is Gaussian with covariance function $E\left[X\left(\xi_{i}, u_{i}\right) X\left(\xi_{j}, u_{j}\right)\right]$.

Remark: Conditions (a)-(c) imply $X_{n}(\xi, u)$ is approximable by a partial sum of martingale differences $E\left[Z_{n, i} \mid \tilde{F}_{n, i}\right]-E\left[Z_{n, i} \mid \tilde{F}_{n, i-1}\right]$. Condition (d) ensures convergence of finite dimensional distributions of $\left\{W_{n}(\xi, u)\right\}$. Conditions (e) and (f) ensure the sequence $\left\{W_{n}(\xi, u)\right\}$ is uniformly tight with respect to $\xi$ and $u$, respectively.

LEMMA A. 2 Under conditions (a)-(d) of Lemma A.1, $W_{n}(\xi, u) \rightarrow W(\xi, u)$ with respect to finite dimensional distributions, where $W(\xi, u)$ is Gaussian with covariance function $E\left[W\left(\xi_{i}, u_{i}\right) W\left(\xi_{j}, u_{j}\right)\right]$.
LEMMA A. 3 Under conditions (e) and (f) of Lemma A. 1 the sequence $\left\{W_{n}(\xi, u)\right\}$ is uniformly tight in $D_{2}$.

## LEMMA A. 4

1. Under Assumption 1.a $\left\{X_{n, t}(u), \digamma_{n, t}\right\}$ forms an $L_{2}$-mixingale sequence (cf. McLeish 1975) with size $-1 / 2$ and constants $\sup _{u \in[0,1], t \geq 1} c_{n, t}(u)=$ $O\left(n^{-1 / 2}\right)$. If particular,

$$
\begin{aligned}
& \left\|X_{n, t}(u)-E\left[X_{n, t}(u) \mid \digamma_{n, t+q}\right]\right\|_{2} \leq c_{n, t}(u) \psi_{q_{n}+1} \\
& \left\|E\left[X_{n, t}(u) \mid \digamma_{n, t-q}\right]\right\|_{2} \leq c_{n, t}(u) \psi_{q_{n}}
\end{aligned}
$$

and if $Y_{n, t}\left(u_{1}, u_{2}\right):=X_{n, t}\left(u_{1}\right)-X_{n, t}\left(u_{2}\right)$ then

$$
\begin{aligned}
& \left\|Y_{n, t}\left(u_{1}, u_{2}\right)-E\left[Y_{n, t}\left(u_{1}, u_{2}\right) \mid \digamma_{n, t+q}\right]\right\|_{2} \leq\left(\tilde{c}_{n, t} \times\left|u_{2}-u_{1}\right|\right) \times \psi_{q_{n}+1} \\
& \left\|E\left[Y_{n, t}\left(u_{1}, u_{2}\right) \mid \digamma_{n, t-q}\right]\right\|_{2} \leq\left(\tilde{c}_{n, t} \times\left|u_{2}-u_{1}\right|^{1 / 2}\right) \times \psi_{q_{n}}
\end{aligned}
$$

$\forall u_{1}, u_{1} \in[0,1]$, where $\sup _{t} \tilde{c}_{n, t}=O\left(n^{-1 / 2}\right)$.
2. Let $\left\{\left(\xi_{i}, u_{i}\right)\right\}_{i=1}^{k,}$ be arbitrary, $k \geq 1,\left(\xi_{i}, u_{i}\right) \in[\underline{\xi}, 1] \times[0,1]$. If additionally Assumption 1.b holds, then

$$
\sup _{\pi^{\prime} \pi=1}\left|\sum_{l=1}^{k} \sum_{i=r_{n}\left(\xi_{l-1}\right)+1}^{r_{n}\left(\xi_{l}\right)}\left(\sum_{j=l}^{k} \pi_{j} Z_{n, i}\left(u_{j}\right)\right)^{2}-1\right| \rightarrow 0, \quad \forall\left\{\left(\xi_{i}, u_{i}\right)\right\}_{i=1}^{k}
$$

LEMMA A. 5 (de Jong, Lemma 4) If $\left\{X_{n, t}, \digamma_{n, t}\right\}$ is an $L_{2}$-mixingale with size $-1 / 2$ and constants $\sup _{t} c_{n, t}=O\left(n^{-1 / 2}\right)$ then

$$
\lim _{n \rightarrow \infty}\left|\sum_{i=1}^{r_{n}} \sum_{k=i+1}^{r_{n}} \sum_{t=(i-1) g_{n}+l_{n}+1}^{i g_{n}} \sum_{s=(k-1) g_{n}+l_{n}+1}^{k g_{n}} E\left[X_{n, s} X_{n, t}\right]\right|=0
$$

LEMMA A. 6 Under Assumption 1, $\sum_{i=1}^{r_{n}(\xi)}\left(Z_{n, i}^{2}(u)-E\left[Z_{n, i}^{2}(u)\right]\right) \rightarrow 0 \forall \xi, u$ $\in[\underline{\xi}, 1] \times[0,1]$.

LEMMA A. 7 Let the conditions of Theorem 6 hold. For any $u \in[0,1]$

$$
k_{n}^{1 / 2}\left(\hat{\alpha}_{m}^{-1}(\xi)-\alpha^{-1}\right)=\sum_{t=1}^{n(\xi)}\left(X_{n, t}-\alpha^{-1} X_{n, t}^{*}\left(u^{1 / \sqrt{k_{n}}}\right)\right)+o_{p}(1)
$$

LEMMA A. 8 Let the conditions of Theorem 6 hold. For any $\tilde{u} \in \mathbb{R}$

$$
\left\{\sum_{t=1}^{n(\xi)} X_{n, t}, \sum_{t=1}^{n(\xi)} X_{n, t}^{*}\left(u^{1 / \sqrt{k_{n}}}\right)\right\} \Rightarrow\left\{X_{1}(\xi), X_{2}(\xi)\right\}
$$

jointly on $D[\underline{\xi}, 1]$, where each $X_{i}(\xi)$ is Gaussian.

Proof of Lemma A.1. Write $X_{n, i}(u)=X_{n, i}, X_{n}(\xi, u)=X_{n}$, etc., and decompose

$$
\begin{align*}
X_{n}= & \sum_{i=1}^{r_{n}(\xi)} W_{n, i}  \tag{17}\\
& +\sum_{i=1}^{r_{n}(\xi)} E\left[Z_{n, i} \mid \tilde{F}_{n, i-1}\right]+\sum_{i=1}^{r_{n}(\xi)}\left(Z_{n, i}-E\left[Z_{n, i} \mid \tilde{F}_{n, i-1}\right]\right) \\
& +\sum_{i=1}^{r_{n}(\xi)} \sum_{t=(i-1) g_{n}+1}^{(i-1) g_{n}+l_{n}} X_{n, t}+\sum_{t=r_{n}(\xi) g_{n}+1}^{n(\xi)} X_{n, t}
\end{align*}
$$

By the definition of an $L_{r}$-Tail Array and $r_{n}(\xi)=\left[n(\xi) / g_{n}\right]$

$$
\left\|\sum_{t=r_{n}(\xi) g_{n}+1}^{n(\xi)} X_{n, t}\right\|_{1}=O\left(\left(n(\xi)-r_{n}(\xi) g_{n}\right) n^{-a(1)}\right)=o(1)
$$

The second-through-fourth terms in (17) are $o_{p}(1)$ by conditions (a)-(c). Hence

$$
\begin{equation*}
X_{n}(\xi, u)=\sum_{i=1}^{r_{n}(\xi)} W_{n, i}(u)+o_{p}(1)=W_{n}(\xi, u)+o_{p}(1) \tag{18}
\end{equation*}
$$

By Lemma A. $2 W_{n}(\xi, u) \rightarrow W(\xi, u)$ with respect to finite dimensional distributions, where $W(\xi, u)$ is Gaussian with covariance function $E\left[W\left(\xi_{i}, u_{i}\right) W\left(\xi_{j}, u_{j}\right)\right]$.

By Lemma A. 3 the sequence $\left\{W_{n}(\xi, u)\right\}$ is uniformly tight on $D_{2}$. Therefore $W_{n}(\xi, u) \Rightarrow W(\xi, u)$ on $D_{2}$ by Corollary 13.4 of Billingsley (1999). We conclude $X_{n}(\xi, u) \Rightarrow X(\xi, u)=W(\xi, u)$ given (18).

Proof of Lemma A.2. Pick any $\pi \in \mathbb{R}^{k}, \pi^{\prime} \pi=1$. For any finite collection $\left\{\left(\xi_{j}, u_{j}\right)\right\}_{j=1}^{k}, \xi_{1} \leq \ldots \leq \xi_{k}$, write

$$
\sum_{j=1}^{k} \pi_{j} W_{n}\left(\xi_{j}, u_{j}\right)=\sum_{i=1}^{r_{n}\left(\xi_{k}\right)} \tilde{W}_{n, i}(u, \pi)
$$

where

$$
\begin{aligned}
& \tilde{W}_{n, i}(u, \pi):=\sum_{j=l}^{k} \pi_{j} W_{n, i}\left(u_{j}\right), i=r_{n}\left(\xi_{l-1}\right)+1 \ldots r_{n}\left(\xi_{l}\right), l=1 \ldots k . \\
& W_{n, i}(u)=\left(E\left[Z_{n, i}(u) \mid \tilde{F}_{n, i}\right]-E\left[Z_{n, i}(u) \mid \tilde{F}_{n, i-1}\right]\right) \\
& \tilde{F}_{n, i}:=\bigcup_{\tau \leq i g_{n}} \digamma_{n, \tau} \text { and } \digamma_{n, t}=\sigma\left(E_{n, \tau}: 1 \leq s \leq \tau \leq t \leq n\right)
\end{aligned}
$$

By construction $\left\{\tilde{W}_{n, i}(u, \pi), \tilde{F}_{n, i}\right\}$ forms a martingale difference sequence. The limit

$$
\sum_{i=1}^{r_{n}\left(\xi_{k}\right)} \tilde{W}_{n, i}(u, \pi) \rightarrow N\left(0, \lim _{n \rightarrow \infty} E\left(\sum_{i=1}^{r_{n}\left(\xi_{k}\right)} \tilde{W}_{n, i}(u, \pi)\right)^{2}\right)
$$

follows from Theorem 2.3 of McLeish (1974), where $\lim _{n \rightarrow \infty}\left\|\sum_{i=1}^{r_{n}\left(\xi_{k}\right)} \tilde{W}_{n, i}(u, \pi)\right\|_{2}$ $\leq k$ follows from (18) and $\left\|X_{n}(\xi, u)\right\|_{2}=1$.

McLeish's condition (c) is our condition (d). Moreover, McLeish's conditions (a) and (b) hold if the Lindeberg condition holds, $\sum_{i=1}^{r_{n}\left(\xi_{k}\right)} E\left[\tilde{W}_{n, i}^{2}(u, \pi) \times\right.$
$\left.I\left(\left|\tilde{W}_{n, i}(u, \pi)\right|>\varepsilon\right)\right] \rightarrow 0$ for any $\varepsilon>0$. Note $|\pi| \leq|\pi|_{2}=1, r_{n}\left(\xi_{k}\right) \leq r_{n}(1)$, and $r_{n}(1) g_{n} \sim n(1) \leq n$. Therefore, for any $\varepsilon>0$

$$
\begin{aligned}
& r_{n}\left(\xi_{k}\right) \max _{i} E\left[\tilde{W}_{n, i}^{2}(u, \pi) I\left(\left|\tilde{W}_{n, i}(u, \pi)\right|>\varepsilon\right)\right] \\
& \quad \leq r_{n}(1) \max _{i}\left\|\tilde{W}_{n, i}(u, \pi)\right\|_{4}^{2}\left\|\tilde{W}_{n, i}(u, \pi)\right\|_{2} \varepsilon^{-1} \\
& \quad \leq r_{n}(1) \max _{i}|\pi| \times \mid \times \sup _{u \in[0,1]}\left\|W_{n, i}(u)\right\|_{4}^{2} \sup _{u \in[0,1]}\left\|W_{n, i}(u)\right\|_{2} \varepsilon^{-1} \\
& \quad \leq K \times r_{n}(1) g_{n}^{2} \sup _{t} \sup _{u \in[0,1]}\left\|X_{n, t}(u)\right\|_{4}^{2} g_{n} \sup _{t} \sup _{u \in[0,1]}\left\|X_{n, t}(u)\right\|_{2} \varepsilon^{-1} \\
& \quad=O\left(r_{n} g_{n}^{2} n^{-2 a(4)} g_{n} n^{-a(2)}\right) \\
& \quad=O\left(g_{n}^{2} n^{1-2 a(4)-a(2)}\right)=o(1),
\end{aligned}
$$

given $g_{n}=o\left(n^{[2 a(4)+a(2)-1] / 2}\right)$. The first inequality is Hölder's and Markov's; the second inequality is Jensen's; the third inequality and first equality follow from the definition of a Functional Tail Array and Minkowski's inequality.

A Crámer-Wold device completes the proof.
Proof of Lemma A.3. Let $\delta \in[0,1]$. Define the metrics $w(\cdot)$ and $w^{\prime \prime}(\cdot)$, cf. Billingsley (1999):

$$
\begin{aligned}
& w\left(W_{n}, \xi, u, \delta\right)=\sup _{\left|\xi-\xi^{\prime}\right| \leq \delta,\left|u-u^{\prime}\right| \leq \delta}\left|W_{n}(\xi, u)-W_{n}\left(\xi^{\prime}, u^{\prime}\right)\right| \\
& w^{\prime \prime}\left(W_{n}, \xi, u, \delta\right)=\sup _{\substack{\xi_{1} \leq \xi \leq \xi_{2} u_{1} \leq u \leq u_{2} \\
\xi_{2}-\xi_{1} \leq \delta \\
u_{2}-u_{1} \leq \delta}}\left\{\left|W_{n}(\xi, u)-W_{n}\left(\xi_{1}, u_{1}\right)\right| \wedge\left|W_{n}(\xi, u)-W_{n}\left(\xi_{2}, u_{2}\right)\right|\right\} .
\end{aligned}
$$

If $\xi$ is fixed at some $\tilde{\xi}$ we write

$$
w\left(W_{n}, \tilde{\xi}, u, \delta\right)=\sup _{\left|u-u^{\prime}\right| \leq \delta}\left|W_{n}(\tilde{\xi}, u)-W_{n}\left(\tilde{\xi}, u^{\prime}\right)\right|
$$

For any triplet $\{\xi, u, \delta\}$ clearly we can find some $\tilde{\xi} \in[\underline{\xi}, 1]$ and $\tilde{u} \in[0,1]$ such that
(19) $w^{\prime \prime}\left(W_{n}, \xi, u, \delta\right) \leq w^{\prime \prime}\left(W_{n}, \tilde{\xi}, u, \delta\right)+w^{\prime \prime}\left(W_{n}, \xi, \tilde{u}, \delta\right)$.

Moreover, by construction (see Billingsley, 1999),
(20) $w^{\prime \prime}\left(W_{n}, \xi, u, \delta\right) \leq w\left(W_{n}, \xi, u, 2 \delta\right) \quad \forall \delta \in[0,1 / 2]$.

From (19)-(20), and equation (13.10) in Billingsley (1999), it suffices to show for every $\varepsilon>0$ and $\eta>0$ there exists some $\delta \in[0,1 / 2]$ and $N \in \mathbb{N}$ such that $\forall n \geq N$

$$
P\left(w^{\prime \prime}\left(W_{n}, \tilde{\xi}, u, \delta\right)>\varepsilon / 2\right)+P\left(w\left(W_{n}, \xi, \tilde{u}, \delta\right)>\varepsilon / 2\right) \leq \eta
$$

The proof now follows from Lemmas A.3.1-A.3.3, below, and Corollary 5.4 and Theorem 13.3 of Billingsley (1999).

LEMMA A.3.1 Let $u \in[0,1]$. Then, $\forall \varepsilon, \eta>0$ there exists some $\delta \in[0,1 / 2]$ and $N_{0} \in \mathbb{N}$ such that $\forall n \geq N_{0}$

$$
P\left(\sup _{\xi \leq \xi^{\prime} \leq \xi+\delta}\left|W_{n}\left(\xi^{\prime}, u\right)-W_{n}(\xi, u)\right|>\varepsilon / 2\right) \leq \eta \delta / 2
$$

Proof of Lemma A.3.1. Drop the common argument $u$ for clarity. Let $Z \sim$ $N(0,1)$ be chosen below. Choose any

$$
\lambda>\max \left\{\varepsilon / \sqrt{2}, 8 \times E|Z|^{3} \times \kappa / \eta \varepsilon^{2}\right\}
$$

and fix

$$
\delta=\varepsilon^{2} / \kappa 4 \lambda^{2} \leq 1 / 2
$$

for some finite $\kappa \geq 1$ to be chosen below.
We can always find a sequence of positive integers $\left\{r_{n}^{*}(\xi)\right\}_{n \geq 1}$ satisfying 0 $\leq\left[r_{n}^{*}(\xi) \delta\right] \leq r_{n}(\xi+\delta)-r_{n}(\xi)$ and $0 \leq r_{n}^{*}(\xi) \leq n(\xi)$ such that

$$
\begin{aligned}
& P\left(\sup _{\xi \leq \xi^{\prime} \leq \xi+\delta}\left|W_{n}\left(\xi^{\prime}\right)-W_{n}(\xi)\right|>\lambda v_{n}\right) \\
& \quad \leq P\left(\sup _{1 \leq j \leq\left[r_{n}^{*}(\xi) \delta\right]}\left|\sum_{i=1}^{r_{n}(\xi)+j} W_{n, i}-\sum_{i=1}^{r_{n}(\xi)} W_{n, i}\right|>\lambda v_{n}\right) \\
& \quad \leq E\left|\sum_{i=r_{n}(\xi)+1}^{r_{n}(\xi)+\left[r_{n}^{*}(\xi) \delta\right]} W_{n, i} / v_{n}\right|^{3} \lambda^{-3}
\end{aligned}
$$

where the second inequality is Kolmogorov's, and $v_{n}:=\left\|\sum_{i=r_{n}(\xi)+1}^{r_{n}(\xi)+\left[r_{n}^{*} \delta\right]} W_{n, i}\right\|_{2}$. By construction

$$
E|Z|^{3} / \lambda^{3}<\eta \varepsilon^{2} / \kappa 8 \lambda^{2}=\eta \delta / 2
$$

and from Lemma A. 2

$$
\sum_{i=r_{n}(\xi)+1}^{r_{n}(\xi)+\left[r_{n}^{*}(\xi) \delta\right]} W_{n, i} / v_{n} \rightarrow Z
$$

Thus, there exists a sufficiently large $N_{0}$ such that $\forall n \geq N_{0}$

$$
E\left|\sum_{i=r_{n}(\xi)+1}^{r_{n}(\xi)+\left[r_{n}^{*}(\xi) \delta\right]} W_{n, i} / v_{n}\right|^{3} \lambda^{-3} \leq \eta \varepsilon^{2} / 8 \lambda^{2}=\eta \delta / 2
$$

Furthermore, by condition (e) of Lemma A. 1 and the martingale difference property we have for some finite $\kappa \geq 1$

$$
v_{n}^{2}=E\left(\sum_{i=r_{n}(\xi)+1}^{r_{n}(\xi)+\left[r_{n}^{*}(\xi) \delta\right]} W_{n, i}\right)^{2}=\sum_{i=r_{n}(\xi)+1}^{r_{n}(\xi)+\left[r_{n}^{*}(\xi) \delta\right]} E\left(W_{n, i}\right)^{2} \leq \delta \times \kappa
$$

Hence, for sufficiently large $N_{0}, \forall n \geq N_{0}$, and $\delta=\varepsilon^{2} / \kappa 4 \lambda^{2}$,

$$
\lambda v_{n} \leq \lambda \delta^{1 / 2} \kappa^{1 / 2}=\varepsilon / 2
$$

We deduce for some $\delta \in[0,1 / 2]$ and $\forall n \geq N_{0}$

$$
P\left(\sup _{\xi \leq \xi^{\prime} \leq \xi+\delta}\left|W_{n}\left(\xi^{\prime}\right)-W_{n}(\xi)\right|>\varepsilon / 3\right) \leq E\left|\sum_{i=r_{n}(\xi)+1}^{r_{n}(\xi)+\left[r_{n}^{*}(\xi) \delta\right]} W_{n, i} / v_{n}\right|^{3} \lambda^{-3} \leq \eta \delta / 2
$$

LEMMA A.3.2 Let $\tilde{\xi} \in[\underline{\xi}, 1]$ be arbitrary. Then $\forall \varepsilon, \eta>0$ there exists some $\delta \in[0,1 / 2]$ and $N_{0} \in \mathbb{N}$ such that $\forall n \geq N_{0}$

$$
P\left(w^{\prime \prime}\left(W_{n}, \tilde{\xi}, u, \delta\right)>\varepsilon / 2\right) \leq \eta / 2
$$

Proof of Lemma A.3.2. Drop the common argument $\xi$. Let $0 \leq u_{1} \leq u_{2} \leq$ $u_{3} \leq 1$ be arbitrary. By condition (f) of Lemma A. 1 and $r_{n}(\tilde{\xi}):=\left[n(\tilde{\xi}) / g_{n}\right]$

$$
\begin{aligned}
& E\left[\left|W_{n}\left(u_{1}\right)-W_{n}\left(u_{2}\right)\right|\left|W_{n}\left(u_{2}\right)-W_{n}\left(u_{3}\right)\right|\right] \\
& \leq\left\|W_{n}\left(u_{1}\right)-W_{n}\left(u_{2}\right)\right\|_{2}\left\|W_{n}\left(u_{2}\right)-W_{n}\left(u_{3}\right)\right\|_{2} \\
& =\left\|\sum_{i=1}^{r_{n}(\tilde{\xi})}\left(W_{n, i}\left(u_{1}\right)-W_{n, i}\left(u_{2}\right)\right)\right\|_{2} \\
& \quad \times\left\|\sum_{i=1}^{r_{n}(\tilde{\xi})}\left(W_{n, i}\left(u_{2}\right)-W_{n, i}\left(u_{3}\right)\right)\right\|_{2} \\
& \quad \\
& \quad=\left|u_{2}-u_{1}\right|^{1 / 2} \times\left|u_{3}-u_{2}\right|^{1 / 2} \times O\left(r_{n}(\tilde{\xi}) g_{n} / n\right) \\
& \leq
\end{aligned}
$$

for some finite $K>0$. Now apply (13.13)-(13.14) of Billingsley (1999).

LEMMA A.3.3 For every $\varepsilon>0, \lim _{\delta \rightarrow 0} P\left(\left|W_{n}(1,1)-W_{n}(1-\delta, 1-\delta)\right|>\right.$ $\varepsilon)=0$.

Proof of Lemma A.3.3. Using conditions (e) and (f) of Lemma A.1, clearly there exists some $\{\tilde{\xi}, \tilde{u}\} \in[\underline{\xi}, 1] \times[0,1]$ such that

$$
\begin{aligned}
& P\left(\left|W_{n}(1,1)-W_{n}(1-\delta, 1-\delta)\right|>\varepsilon\right) \\
& \quad \leq P\left(\left|W_{n}(\tilde{\xi}, 1)-W_{n}(\tilde{\xi}, 1-\delta)\right|>\varepsilon / 2\right)+P\left(\left|W_{n}(1, \tilde{u})-W_{n}(1-\delta, \tilde{u})\right|>\varepsilon / 2\right) \\
& \quad \leq 4 \varepsilon^{-2}\left[\left\|W_{n}(\tilde{\xi}, 1)-W_{n}(\tilde{\xi}, 1-\delta)\right\|_{2}^{2}+\left(r_{n}(1)-r_{n}(1-\delta)\right)^{2} \sup _{i \geq 1}\left\|W_{n, i}(\tilde{u})\right\|_{2}^{2}\right] \\
& \quad \leq 4 \varepsilon^{-2}\left[K \times \delta^{2}+\left(r_{n}(1)-r_{n}(1-\delta)\right)^{2} \sup _{i \geq 1}\left\|W_{n, i}(\tilde{u})\right\|_{2}^{2}\right]
\end{aligned}
$$

As $\delta \rightarrow 0$ the right-hand-side vanishes due to $r_{n}(1-)=r_{n}(1)$ given $n(1-)=$ $n(1)$.

## Proof of Lemma A.4.

Step 1: If the base $\left\{\epsilon_{n, t}\right\}$ is E-strong mixing then Theorem 17.5 of Davidson (1994) implies

$$
\begin{aligned}
\| X_{n, t}(u)- & E\left[X_{n, t}(u) \mid \digamma_{n, t-q}\right] \|_{2} \\
& \leq \max \left\{\left\|X_{n, t}(u)\right\|_{r}, d_{n, t}(u)\right\} \times \max \left(6 \varepsilon_{q_{n}}^{1 / 2-1 / r}, \varphi_{q_{n}}\right)
\end{aligned}
$$

By assumption $n^{a(r)-1 / 2} q_{n}^{r /(r-2)} \varepsilon_{q_{n}}=o(1), \sup _{t} \sup _{u \geq 0}\left\|X_{n, t}(u)\right\|_{r}=O\left(n^{-a(r)}\right)$, $\sup _{t} \sup _{u \geq 0} d_{n, t}(u)=O\left(n^{-a(r)}\right)$, and $\varphi_{q_{n}}=o\left(n^{a(r)-1 / 2} \times q_{n}^{-1 / 2}\right)$. We may therefore write for sufficiently large $K>0$,

$$
\begin{aligned}
& \left\|X_{n, t}(u)-E\left[X_{n, t}(u) \mid \digamma_{n, t-q}\right]\right\|_{2} \\
& \quad \leq K \times n^{-1 / 2} \max \left\{\left(n^{[1 / 2-a(r)] 2 r /[r-2]} \varepsilon_{q_{n}}\right)^{1 / 2-1 / r}, n^{1 / 2-a(r)} \varphi_{q_{n}}\right\} \\
& \quad=c_{n, t}(u) \times \psi_{q_{n}}
\end{aligned}
$$

say, where $\sup _{t} \sup _{u \geq 0} c_{n, t}(u)=O\left(n^{-1 / 2}\right)$ is trivial and $\psi_{q_{n}}=o\left(q_{n}^{-1 / 2}\right)$ follows from the properties of E-Mixing and FE-NED coefficients. A similar argument holds for the remaining mixingale bound, $\left\|X_{n, t}(u)-E\left[X_{n, t}(u) \mid \digamma_{n, t+q}\right]\right\|_{2} \leq$ $c_{n, t}(u) \times \psi_{q_{n}+1}$, and in the E-uniform mixing case. Consult Davidson (1994).

An identical argument can be applied to $Y_{n, t}\left(u_{1}, u_{2}\right)=X_{n, t}\left(u_{1}\right)-X_{n, t}\left(u_{2}\right)$.
Step 2: The limit

$$
\sup _{\pi^{\prime} \pi=1}\left|\sum_{l=1}^{k} \sum_{i=r_{n}\left(\xi_{l-1}\right)+1}^{r_{n}\left(\xi_{l}\right)}\left(\sum_{j=l}^{k} \pi_{j} Z_{n, i}\left(\xi_{j}, u_{j}\right)\right)^{2}-1\right| \rightarrow 0
$$

$\forall l=1 \ldots k$ and each $\left\{\left(\xi_{i}, u_{i}\right)\right\}_{i=1}^{k,}$ now follows from Lemmas A. 5 and A. 6 and an argument identical to de Jong's (1997: A.39-A.41).

Proof of Lemma A.6. Because $u$ and $\xi$ are arbitrary, the claim follows from Lemma A. 4 of Hill (2005b).

Proof of Lemma A.7. Write $b_{[n \xi]}=b_{[n \xi]}\left(\left[k_{n} \xi\right]\right)$ and

$$
\begin{aligned}
k_{n}^{1 / 2} & \left(\hat{\alpha}_{m}^{-1}(\xi)-\alpha^{-1}\right) \\
= & k_{n}^{1 / 2}\left(1 /\left[k_{n} \xi\right] \sum_{i=1}^{\left[k_{n} \xi\right]} \ln X_{(i)} / X_{\left(\left[k_{n} \xi\right]+1\right)}-\alpha^{-1}\right) \\
= & k_{n}^{1 / 2}\left(1 /\left[k_{n} \xi\right] \sum_{i=1}^{\left[k_{n} \xi\right]} \ln X_{(i)} / b_{[n \xi]}-E\left(1 /\left[k_{n} \xi\right] \sum_{t=1}^{[n \xi]}\left(\ln X_{t} / b_{[n \xi]}\right)_{+}\right)\right) \\
& \quad-k_{n}^{1 / 2} \ln X_{\left(\left[k_{n} \xi\right]+1\right)} / b_{[n \xi]}+k_{n}^{1 / 2}\left[E\left(1 /\left[k_{n} \xi\right] \sum_{t=1}^{[n \xi]}\left(\ln X_{t} / b_{[n \xi]}\right)_{+}\right)-\alpha^{-1}\right] .
\end{aligned}
$$

From (12) and arguments in Hsing (1991: p. 1554)

$$
\begin{equation*}
E\left(1 /\left[k_{n} \xi\right] \sum_{t=1}^{[n \xi]}\left(\ln X_{t} / b_{[n \xi]}\right)_{+}-\alpha^{-1}\right)=o\left(1 / \sqrt{\left[k_{n} \xi\right]}\right) \tag{22}
\end{equation*}
$$

Moreover, from Lemma A. 8

$$
\left\{\sum_{t=1}^{[n \xi]} X_{n, t}, \sum_{t=1}^{[n \xi]} X_{n, t}^{*}\left(u^{1 / \sqrt{k_{n}}}\right)\right\} \Rightarrow\left\{X_{1}(\xi), X_{2}(\xi)\right\}
$$

jointly on $D[\underline{\xi}, 1]$, where each $X_{i}(\xi)$ is Gaussian. Furthermore, under the maintained assumptions $\left|\ln X_{\left(\left[\rho\left[k_{n} \xi\right]\right]\right)}-\ln b_{n}\left(\rho\left[k_{n} \xi\right]\right)\right| \rightarrow 0$ for all $\rho$ in an arbitrary neighborhood of 1 by Lemma 1 of Hill (2005b). Therefore an argument identical to Theorem 2.2 of Hsing (1991: eq. 2.4-2.7) applies:

$$
\begin{aligned}
& k_{n}^{1 / 2}\left(\frac{1}{\left[k_{n} \xi\right]} \sum_{i=1}^{\left[k_{n} \xi\right]} \ln X_{(i)} / b_{[n \xi]}-E\left(\frac{1}{\left[k_{n} \xi\right]} \sum_{t=1}^{[n \xi]}\left(\ln X_{t} / b_{[n \xi]}\right)_{+}\right)\right) \Rightarrow X_{1}(\xi) \\
& \alpha \times \sum_{t=1}^{[n \xi]} X_{n, t}^{*}\left(u^{1 / \sqrt{k_{n}}}\right)=\alpha \times \sum_{t=1}^{[n \xi]} X_{n, t}^{*}\left(\tilde{u} / \sqrt{k_{n}}\right) \Rightarrow X_{2}(\xi)
\end{aligned}
$$

where

$$
\begin{aligned}
& X_{n, t}^{*}(\tilde{u}):=k_{n}^{-1 / 2}\left(I\left(X_{t}>b_{n}\left(k_{n}\right) e^{\tilde{u}}\right)-E\left[I\left(X_{t}>b_{n}\left(k_{n}\right) e^{\tilde{u}}\right)\right]\right) \\
& \tilde{u}=-(1 / \alpha) \ln u .
\end{aligned}
$$

Together, (21)-(23) imply

$$
k_{n}^{1 / 2}\left(\hat{\alpha}_{m}^{-1}(\xi)-\alpha^{-1}\right)=\sum_{t=1}^{[n \xi]}\left(X_{n, t}-\alpha^{-1} X_{n, t}^{*}\left(u^{k_{n}^{-1 / 2}}\right)\right)+o_{p}(1)
$$

Proof of Lemma A.8. If $\left\{X_{n, t}, X_{n, t}^{*}(u)\right\}$ are $L_{r}$-Tail Arrays with moment index $a(r)$ then by Minkowski's inequality so is $\left\{\pi_{1} X_{n, t}+\pi_{2} X_{n, t}^{*}(u)\right\} \forall \pi \in \mathbb{R}^{2}$, $\pi^{\prime} \pi=1$. Moreover, under the maintained assumptions Lemma 4 and Theorem 17.8 of Davidson (199) imply $\left\{\pi_{1} X_{n, t}+\pi_{2} X_{n, t}^{*}(u)\right\}$ is $L_{2}$-NED on $\left\{\digamma_{n, t}\right\}$ with size $-1 / 2$. The claim now follows by applying Corollary 4 to $\left\{\pi_{1} X_{n, t}+\right.$ $\left.\pi_{2} X_{n, t}^{*}\left(u^{k_{n}^{-1 / 2}}\right)\right\}$ and invoking a Cramér-Wold device.
