Abstract

The classical theory of rational choice is built on several important internal consistency conditions. In recent years, the reasonableness of those internal consistency conditions has been questioned and criticized, and several responses to accommodate such criticisms have been proposed in the literature. This paper develops a general framework to accommodate the issues raised by the criticisms of classical rational choice theory, and examines the broad impact of these criticisms from both normative and positive points of view.

Keywords: choice, internal consistency, rationality, distinguishability, menu-dependent criteria and information

JEL Classification Numbers: D0, D1

1. Introduction

The literature on the theory of choice and preference contains a large number of “internal consistency conditions”, such as Chernoff’s condition (see Chernoff 1954), the weak axiom of revealed preference (see Samuelson 1938, 1947, 1948, and Arrow 1959), the strong axiom of revealed preference (see Houthakker 1950, and Arrow 1959), and the congruence axiom (see Richter 1966, 1971). Typically, these conditions take the following general form: if an agent chooses (or does not choose) certain options from sets A, B, \dots of feasible options, then the agent will (or, alternatively, will not) choose certain options from sets A', B', \dots of feasible options.¹ The conditions play dual conceptual roles in the standard theory of choice. First, they are treated as properties of rational choice, the (often implicit) claim being that, if the agent is “rational”, then her choices must satisfy these conditions. Second, they are also treated as testable hypotheses regarding the agent’s choice behavior. The focus of this paper is on the former interpretation though we also comment briefly on the latter interpretation.

While the internal consistency conditions have been widely accepted as conditions that a rational agent should satisfy, from time to time examples have appeared in the literature to question that position. The earliest examples that we know of are to be found in Luce and Raiffa (1957). More recently, Sen (1993) has introduced some further examples in the same spirit and has argued that the reasonableness or intuitive appeal of these conditions cannot be judged without referring to the motives and objectives of the agent making choices. The examples of Luce and Raiffa (1957) and Sen (1993) and other similar examples pose a challenge to the standard theory of rational choice. In particular, they raise the following two questions. First, is there a general reformulation of the conventional theory of rational choice that can accommodate examples of the type discussed by Luce and Raiffa and Sen? Second, if at all one can find such a reformulation, will it constitute a satisfactory response to Sen’s argument that

¹ For example, the weak axiom of revealed preference, one of the most well-known of such conditions, says that, if, given a set of options that contains both x and y , the agent chooses x and rejects y , then, given any other set that contains x , the agent does not choose y .

internal consistency conditions, by themselves, cannot constitute adequate intuitive criteria for assessing whether the agent's choices are rational?

The main purpose of this paper is to explore these two issues. We first develop a general framework, which is a reformulation of the conventional theory, to accommodate the examples of Luce and Raiffa and Sen and the like. Next we argue that, though our reformulation of the conventional theory, as well as other less general reformulations² in the existing literature, can take care of the problem of internal inconsistency of choice in the examples under consideration, this does not in any way detract from Sen's basic argument that the reasonableness of internal consistency conditions as conditions for rational choice cannot be judged without going into the agent's motives and objectives.

The plan of the paper is as follows. In Section 2, we introduce some basic notation and definitions. In Section 3, we present several examples and discuss their structural features. In Section 4, we develop a general framework that can accommodate the examples discussed in Section 3. In Section 5, we comment on several existing formulations that deal with issues raised by the examples showing violations of internal consistency conditions. In Section 6, we provide an assessment of what we believe to be the central point of Sen's analysis, namely, that the reasonableness of internal consistency conditions for choice cannot be decided without referring to the objectives and motives of the agent making the choices. Section 7 contains brief remarks on our model and on some broader issues relating to the theory of rational choice.

2. The basic notation and definitions

An agent is described by a triple $\langle X, \mathcal{X}, C \rangle$, where X is a given non-empty set of options, \mathcal{X} is a non-empty class of non-empty subsets of X , and C is a function, which, for every $A \in \mathcal{X}$, specifies exactly one non-empty subset of A , to be denoted by $C(A)$. \mathcal{X} is to be interpreted as the different non-empty sets of feasible alternatives (*menus* or *opportunity sets*) with which the agent under consideration may be confronted, and, given a menu, A , $C(A)$ is to be interpreted as the set of options that the agent chooses from A . We call C the *choice function* of the agent.

² See Section 5 for a discussion of some of these reformulations.

Definition 2.1. Consider an agent described by $\langle X, \mathcal{X}, C \rangle$. The choice function C satisfies:

- (i) *Chernoff's condition* iff, for all $A, B \in \mathcal{X}$ and all $x, y \in X$, if $A \subseteq B$ and $[x \in C(A)$ and $y \in A - C(A)]$, then $\text{not}[y \in C(B)]$;
- (ii) the *weak axiom of revealed preference* iff, for all $A, B \in \mathcal{X}$ and all $x, y \in X$, if $[x \in C(A)$ and $y \in A - C(A)]$, then $\text{not}[y \in C(B)$ and $x \in B]$;
- (iii) the *congruence axiom* iff there do not exist a positive integer n , menus $A_1, \dots, A_n, A_{n+1} \in \mathcal{X}$, and $x_1, x_2, \dots, x_n \in X$, such that, for all $t \in \{1, 2, \dots, n\}$, $[x_t \in C(A_t)$ and $x_{t+1} \in A_t]$ and $[x_{n+1} \in C(A_{n+1})$ and $x_1 \in (A_{n+1} - C(A_{n+1}))]$;
- (iv) *rationalizability in terms of an ordering* iff there exists an ordering, \succsim , defined over X , such that, for all $A \in \mathcal{X}$, $C(A)$ is the set of \succsim -greatest elements in A .

The properties introduced in Definition 2.1 are very familiar in the literature³. The first three of these properties, Chernoff's condition, the weak axiom of revealed preference, and the congruence axiom are in ascending order of logical strength, and the congruence axiom is a necessary and sufficient condition for the choice function C to be rationalizable in terms of an ordering (see Richter 1966). Chernoff's condition, which requires that, if an option x is revealed to be strictly better than an option y in a set A , then, when the set A is enlarged to a set B , y cannot be revealed to be at least as good as x in the set B , is the weakest of the four properties and seems highly plausible. As we shall, however, see in Examples 3.1 through 3.4 below, when choices are menu-dependent, this condition becomes immediately questionable. The weak axiom of revealed preference requires that, whenever an option x is revealed to be better than an option y in a set A , y cannot be revealed to be at least as good as x in another set B . The congruence axiom says that if an option x is revealed to be at least as good as an option y through possibly a chain of feasible sets, then y cannot be revealed to be better than x in any set. Rationalizability of C in terms of an ordering, which is logically equivalent to the congruence axiom for C , requires that the agent's choices should be compatible with the standard notion of "preference optimization", i.e., there should exist an ordering such that the

³ See Chernoff (1954) for Chernoff's condition, Samuelson (1938, 1947) for the weak axiom of revealed preference, and Richter (1966) for the congruence axiom.

set of options chosen by the agent from any given admissible menu would coincide with the set of best alternatives defined for that menu by that ordering.

3. Examples

Example 3.1 (Sen 1993). In a party, when the fruit tray comes to an individual, there are several pears and one apple in the tray. He chooses a pear. If, however, the tray had an additional apple, he would have chosen an apple. The individual's choices violate Chernoff's condition. The explanation lies in the fact that, when the tray contains only one apple, choosing it violates social norms ("a polite person does not pick up a fruit if it happens to be the single fruit of its type in the tray").

Example 3.2. In a firm, there has been a long-standing rule that all customers' queries must be responded to within a week. A given employee, say, i , of the firm, however, disposes of all such queries directed to him in 4 days. A new manager comes in and introduces a rule saying that all customers' queries must be dealt with in no more than 4 days. After the rule is introduced, i responds to all queries in 2 days. The choice behavior of the employee violates Chernoff's condition. A possible reason may be how i wants to be seen. Given the rule that the job must be done in no more than x number of days, i does not want to be seen as someone who works at the margin of the rules by finishing the job exactly in x days. At the same time, he does not want to jump up and finish the job immediately because, if he does so, he is likely to be seen as the "management's poodle". So he settles for some safe point between the two extremes, namely, x days and 0 days, and, in the process, violates Chernoff's condition.

Note that, in Examples 3.1 and 3.2, in judging an option, the agent is using a criterion (possibly, with other criteria) that depends on the set of feasible alternatives from which the option is being chosen. In Example 3.1, the criterion of fulfilling social norms depends on whether the chosen fruit is the single fruit of its type in the feasible set. In Example 3.2, the criterion is one of taking the safe "middle path" between the maximum possible days allowed by the manager to respond to customer queries and 0 days. The "middle path" constitutes a menu-dependent evaluative criterion. Examples similar to Example 3.2 can be found in

empirical studies of consumers' behavior (see, for example, Simonson 1989). Examples 3.1 and 3.2 illustrate what we shall call the agent's *menu-dependent criteria* for judging options.

Example 3.3 (Luce and Raiffa 1957). The waiter in a restaurant gives a customer a menu for the day's dishes, which has two items: steak and fish. The customer orders fish. The waiter subsequently reports that, because of a mistake, frog's legs and fried snails have been omitted from the day's menu but they are available. The customer then orders steak. Again, this is a violation of Chernoff's condition. The intuition is that the customer would choose steak rather than fish or fried snails or frog's legs if he has some assurance that the restaurant is good ("an indifferent restaurant would not know how to handle steak") and the customer's experience tells him that fried snails and frog's legs are served only by good restaurants.

Example 3.4. The following is a true story of a university professor. The professor spent at least 4 hours each week to discuss with his two research students their academic problems. Then the chair of his department imposed a rule, which required that each supervisor of doctoral dissertations must devote no less than one hour each week to each of his Ph. D. students. After the rule was introduced, our professor devoted exactly one hour each week to discussions with each of his Ph. D. students. The professor's choices obviously violated Chernoff's condition. There can be several alternative explanations of the professor's behavior. But the one, which the professor himself gave, was the following: "if the university does not trust me to do a good job of supervising my students on my own, then I am going to follow exactly the rules introduced by the university." In this case, the feasible set for the professor acted as an indicator of the chair's trust, and trust and reciprocation for trust were important considerations for the professor. The professor's behavior cannot be dismissed as the eccentric behavior "typical of academics". There seems to be some evidence that too many rules and regulations governing the behavior of workers on the shop floor may actually adversely affect the work that they put in. In a laboratory setting, Fehr, Klein, and Schmidt (2007) study the effects of two different contracts, "bonus contract" with less rules and relying on trust, and "incentive contract" with detailed rules regarding workers' efforts and relying on

verifications by a third party, and find that bonus contracts can outperform incentive contracts in inducing workers' effort.

In Examples 3.3 and 3.4, the menu from which the agent makes his choice gives him more information about the options. They constitute examples of what we shall call *menu-dependent information*.⁴ Note that, Examples 3.3 and 3.4 share one feature of Examples 3.1 and 3.2. In Examples 3.3 and 3.4, as in Examples 3.1 and 3.2, the agent has concerns that are not captured in the original descriptions of the options: the description "steak", in itself, does not capture the quality of the steak with which the agent is concerned in Example 3.3; nor does the description, "spending x hours each week to discuss with the students" say anything about the chair's trust in the professor--a criterion or concern of the agent in Example 3.4. There is, however, one difference between Examples 3.1 and 3.2 on the one hand and Examples 3.3 and 3.4 on the other. Neither the criterion represented by the social norm of not picking up an only fruit of its type (see Example 3.1) nor the criterion of the "middle path" (see Example 3.2) can be articulated without referring to a menu. In Example 3.3, however, the criterion of quality can, in principle, be articulated without any reference to the menu where "steak" figures; similarly, in Example 3.4, the criterion of appropriate reciprocation for trust also can be stated without any reference to the menu where the option "spending x hours each week to discuss with the student" figures. Thus, the criteria under consideration in Examples 3.3 and 3.4 are definable without any reference to a menu; what seems to be menu-dependent in Example 3.3 (resp. Example 3.4) is the agent's (imperfect) information, at the time of choosing, about the fulfillment of the relevant criterion when he chooses the option "steak" (resp. the option "spending x hours each week to discuss with the students")⁵. This difference provides the basis of our distinction between situations of "menu-dependent criteria" and situations of "menu-dependent information".

⁴ In this paper, we focus on some conceptual issues that arise in the presence of menu-dependent criteria and menu-dependent information. Similar issues, however, can arise even in the absence of menu-dependent criteria/information when the agent's choice from a given menu is influenced by the state of the world and the state of the world is not a part of the description of the options. A consumer, who chooses cold salad over hot soup if the weather is very warm but chooses hot soup over cold salad if the weather is cold, manifests such "state-dependence" (see Bandyopadhyay, Dasgupta, and Pattanaik 1999, 2004).

⁵ As we explain in Section 4, in Examples 3.3 and 3.4 the agent can be seen as choosing in a situation of uncertainty.

Examples 3.1 through 3.4 show that, in certain fairly plausible situations, the agent's choice function can violate Chernoff's condition, which constitutes one of the weakest of consistency conditions discussed in the literature. Yet, in none of these examples, the agent acts in a way that one can reasonably call "irrational". The above examples show how reasonable agents may violate internal consistency conditions for choice. More importantly, they all illustrate a broader methodological point, forcefully made by Sen, that the reasonableness of the internal consistency properties of choice cannot be determined without considering the criteria or motives behind the agent's choices. In Examples 3.1 and 3.2, as well as in Examples 3.3 and 3.4, the agent's violation of Chernoff's condition does not seem irrational at all once we know the reasons behind the agent's choices. The conclusion that Sen sought to draw from his examples was that it was not possible to formulate the theory of rational choice exclusively in terms of internal consistency of choices without going beyond choice as such to explore the criteria or motives guiding the agent's choices.

Examples 3.1 through 3.4 naturally raise the following issues.

Issue 1. Can the phenomena described in these examples be accommodated in the standard framework of revealed preference theory by plausibly reformulating the model so that the consistency conditions will not be violated in the reformulated model?

Issue 2. If at all it is possible to reformulate the model so as to accommodate the phenomena described in the examples without any violation of internal consistency conditions in the reformulated model, then what are the implications of such reformulation for the basic methodological point raised by Sen, to wit, whether one can discuss the reasonableness of internal consistency conditions without going beyond the concept of choice to look into the objectives guiding the agent's choices?

Issue 3. The problems raised by Examples 3.1 through 3.4 have been typically discussed in the context of the theory of revealed preference where one starts with the primitive notion of choice rather than with preferences of the agent. Do similar problems arise in models where one starts with the primitive notion of preference?

Issue 4. Finally, what happens if we treat the consistency conditions for choice as empirically testable hypotheses rather than as normative conditions for the agent’s “rationality”?

In Section 4, we take up the first issue. We show that it is indeed possible to adapt the basic model so that the agent’s behavior, when considered in the adapted version of the original model, will not violate the relevant internal consistency condition for choice. In Section 6, we take up the other three issues noted above.

4. A general framework to handle the phenomena of menu-dependent criteria and menu-dependent information

Faced with the violation of internal consistency conditions in situations involving menu-dependent criteria, one of the typical responses of theorists has been to reformulate some or all the characterizing features (the universal set of alternatives, the set of potential menus, and the choice function) of the agent in a way that gets rid of such violation. In this section, we present a reformulation of the conventional theory to accommodate Examples 3.1 and 3.2 discussed earlier. Though, for the purpose of our discussion, we focus on the case of menu-dependent criteria, at the end of this section we indicate how similar reformulations can deal with menu-dependent information (Examples 3.3 and 3.4).

In Example 3.1, as well as in Example 3.2, the agent uses a menu-dependent criterion⁶ to assess the options available in alternative menus. Every such criterion refers to some features of the choice of a given alternative from a given menu. The analytical strategy that we adopt is to introduce the notion of *indistinguishability/distinguishability*, in terms of the relevant features, between the choice of an option from one menu and the choice of the same option from another menu.

Consider a case of menu-dependent criteria, where $\langle X, \mathcal{X}, C \rangle$ is the “initial” description of the agent, and C violates some internal consistency condition, say, Chernoff’s condition. For ease of presentation and without loss of generality, we assume that, for all x in X , there exists

⁶ In general, there may be more than one menu-dependent criterion. Therefore, strictly speaking, outside the specific examples considered here it would be more appropriate to talk about “a set of menu-dependent criteria” rather than “a menu-dependent criterion”. We would, however, use the two terms interchangeably.

some $A \in \mathcal{X}$ such that $x \in A$. For all $x \in X$, let \sim_x be a reflexive, symmetric, and transitive binary relation defined over the set Z_x , where Z_x is defined as the set of all *ordered* pairs (x, A) such that $x \in A \in \mathcal{X}$; thus, \sim_x is an equivalence relation defined over Z_x . Our intended intuitive interpretation of $(x, A) \sim_x (x, B)$ is that, in terms of the descriptive features referred to by the menu-dependent criteria (or, criterion) under consideration, choosing x from the set A is *indistinguishable* from choosing x from the set B . Thus, for every $x \in X$, \sim_x is induced by the menu-dependent criteria under consideration. In Example 3.1, where the menu-dependent criterion is that of not choosing a fruit from a fruit tray if the fruit happens to be the only one of its type in the tray, if x is a particular apple that belongs to two different sets, A and B , of fruits, then $(x, A) \sim_x (x, B)$ if and only if either x is the only apple in A as well as in B or x is not the only apple in either A or B . Note that, for distinct alternatives $x, y \in X$, we have not introduced any notion of distinguishability or otherwise between choosing x from a set $A \in \mathcal{X}$ and choosing y from a set $B \in \mathcal{X}$ (irrespective of whether or not A and B are identical) because we do not need this additional information for our purpose.

It may be worth clarifying the intuitive content of the equivalence relations \sim_x, \sim_y , etc. Our notion of equivalence relations such as \sim_x, \sim_y , etc., is different from the concept of an ordering over $\{(a, A): a \in A \in \mathcal{X}\}$, that makes comparisons of the type “the choice of x from the menu A fulfills the menu-dependent criteria at least as much as the choice of b from the menu B .” Not only is it true that our equivalence relations, \sim_x, \sim_y, \dots , do not presuppose, either formally or intuitively, any ordering over $\{(a, A): a \in A \in \mathcal{X}\}$, but the intuitive interpretation that we have for these equivalence relations is also very different from the notion of fulfilling the menu-based criteria to the same extent. Given the descriptive features relevant for the menu-dependent criteria, our notion of indistinguishability between (x, A) and (x, B) in Z_x refers to indistinguishability in terms of those descriptive features rather than in terms of identical degrees of fulfillment of the menu-dependent criteria. Indistinguishability in terms of the relevant descriptive features intuitively entails identical degrees of fulfillment of the menu-dependent criteria, but the converse is not necessarily true. Note that, though we have chosen to interpret our equivalence relations as relations indicating indistinguishability in terms of the descriptive features relevant for the menu-dependent criteria and not as relations

indicating identical degrees of fulfillment of the menu-dependent criteria, it may be noted that much of what we say below applies to both these interpretations.

Let $\{\sim_x\}_{x \in X}$ be a given set of equivalence relations interpreted as above. For all $x \in X$, we say that \sim_x is *trivial* if and only if, for all $A, B \in \mathcal{X}$, $(x, A) \sim_x (x, B)$ implies $A = B$. For all $(x, A) \in Z_x$, let $E[x, A]$ be the equivalence class of (x, A) defined by \sim_x , i.e., $E[x, A]$ is the class of all $(x, B) \in Z_x$, such that $(x, B) \sim_x (x, A)$. Clearly, $E[x, A]$ is a singleton if \sim_x is a trivial equivalence relation. Note that, though formally one can consider any arbitrarily specified set, $\{\sim_x\}_{x \in X}$, of equivalence relations, to make intuitive sense these equivalence relations need to be suitably interpreted in terms of the menu-dependent criteria under consideration.

Having introduced the relevant equivalence relations $\{\sim_x\}_{x \in X}$ and the corresponding equivalence classes, we can now transform the initial description, $\langle X, \mathcal{X}, C \rangle$, of the agent in our example of menu-dependent criteria into a new description $\langle X_*, \mathcal{X}_*, C_* \rangle$ specified as follows:

$$X_* \text{ is the set of all ordered pairs } (x, E[x, A]) \text{ such that } x \in A \in \mathcal{X}; \quad (4.1)$$

$$\mathcal{X}_* \text{ is the class of all } A_* \text{ such that for some } A \in \mathcal{X}, A_* = \{(x, E[x, A]): x \in A\}; \quad (4.2)$$

$$C_* \text{ is a function, which, for every } A_* \in \mathcal{X}_*, \text{ specifies the unique set } \{(z, E[z, A]): A \in \mathcal{X}; A_* = \{(x, E[x, A]): x \in A\}; \text{ and } z \in C(A)\}. \quad (4.3)$$

It is clear that, given the set, $\{\sim_x\}_{x \in X}$, of equivalence relations, there exists a unique triple $\langle X_*, \mathcal{X}_*, C_* \rangle$ satisfying (4.1), (4.2) and (4.3). Essentially, what is involved in the transition from the description of the agent in terms of $\langle X, \mathcal{X}, C \rangle$ to the description in terms of $\langle X_*, \mathcal{X}_*, C_* \rangle$ is the replacement of the original notion of an option by an “extended” notion of an option to capture an aspect that is relevant for the agent’s choices but does not figure in the original description of an option. The concept of the class of potential menus, as well as the concept of options chosen from a menu, is then adjusted accordingly. It may be noted that the transformed description of an agent by $\langle X_*, \mathcal{X}_*, C_* \rangle$ depends on the underlying class of

equivalence relations $\{\sim_x\}_{x \in X}$, which, in turn, are determined by the given menu-dependent criteria.

How does our reformulated framework tackle the violation of Chernoff's condition considered in Examples 3.1 and 3.2? To answer this question, we first note the following result. Its proof can be found in the appendix.

Proposition 4.1. Let $\langle X, \mathcal{X}, C \rangle$ be any given initial description of the agent and let $\{\sim_x\}_{x \in X}$ be a given class of equivalence relations. Let $\langle X_*, \mathcal{X}_*, C_* \rangle$ be the modified description of the agent satisfying (4.1), (4.2), and (4.3).

- (i) If C satisfies any of the properties (Chernoff's condition, the weak axiom of revealed preference, the congruence axiom, and rationalizability in terms of an ordering) introduced in Definition 2.1, then C_* must satisfy the same condition.
- (ii) If, for all $x \in X$, \sim_x is trivial, then C_* must satisfy all the properties (Chernoff's condition, the weak axiom of revealed preference, the congruence axiom, and rationalizability in terms of an ordering) introduced in Definition 2.1
- (iii) It is possible for C_* to satisfy all the properties introduced in Definition 2.1 even when, for all $x \in X$, \sim_x is non-trivial and C violates Chernoff's condition, the weakest of the properties introduced in Definition 2.1.

Propositions 4.1 (i) and 4.1 (iii) show that the requirement of any of the four properties, namely, Chernoff's condition, the weak axiom of revealed preference, the congruence axiom, and rationalizability in terms of an ordering, for the choice function C_* figuring in the new description $\langle X_*, \mathcal{X}_*, C_* \rangle$ is weaker than the requirement of the same property for the choice function C figuring in the initial description $\langle X, \mathcal{X}, C \rangle$. Therefore, when C_* satisfies, say, Chernoff's condition but C does not, we can say that, though the agent, described by $\langle X, \mathcal{X}, C \rangle$, violates Chernoff's condition, the violation is really due to the fact that he regards the choice of an option x from some feasible set A to be distinguishable from the choice of the same option x from some subset B of A , and when the problem is re-formulated to take into account such "distinguishability" of acts of choosing in addition to the features of the initial options, the violation of Chernoff's condition disappears in the re-formulated choice problem.

Proposition 4.1 (ii) shows that when all the equivalence relations in $\{\sim_x\}_{x \in X}$ are trivial, C_* must satisfy all our rationality conditions irrespective of whether C satisfies any of the rationality property. Proposition 4.1 (ii), therefore, shows that, if, instead of being determined by exogenously given menu-dependent criteria, the equivalence relations can be specified in any way one likes, then one can always specify the equivalence relations in such a way that, when the model of the agent's choices is reformulated with reference to such specification, the agent's choice function in the reformulated model will necessarily satisfy all our rationality conditions.

Having reformulated the initial description, $\langle X, \mathcal{X}, C \rangle$, of the agent so as to derive the new description, $\langle X_*, \mathcal{X}_*, C_* \rangle$, which satisfies (4.1), (4.2), and (4.3), we can now define a modified notion of rationalizability of the initial choice function C in terms of an ordering. The choice function C is said to satisfy $\langle X_*, \mathcal{X}_*, C_* \rangle$ -based *rationalizability in terms of an ordering* iff C_* is rationalizable in terms of an ordering.

The following proposition follows immediately from the definition of $\langle X_*, \mathcal{X}_*, C_* \rangle$ -based rationalizability in terms of an ordering and the fact that, for every choice function, the congruence axiom is equivalent to rationalizability of that choice function in terms of an ordering (see Richter 1966).

Proposition 4.2. Let $\langle X, \mathcal{X}, C \rangle$ be the initial description of the agent, and let $\langle X_*, \mathcal{X}_*, C_* \rangle$ be the modified description satisfying (4.1), (4.2), and (4.3). C satisfies $\langle X_*, \mathcal{X}_*, C_* \rangle$ -based rationalizability in terms of an ordering iff C_* satisfies the congruence axiom.

It may be noted that, when, for all $x \in X$ and all $(x, A), (x, B) \in Z_x$, $(x, A) \sim_x (x, B)$, $\langle X_*, \mathcal{X}_*, C_* \rangle$ -based rationalizability of C in terms of an ordering becomes equivalent to the standard rationalizability of C in terms of an ordering. On the other hand, by Proposition 4.1 (ii), when, for all $x \in X$, \sim_x is trivial, any choice function C satisfies $\langle X_*, \mathcal{X}_*, C_* \rangle$ -based

rationalizability in terms of an ordering.⁷ Given this observation, it is clear that every choice function C satisfies $\langle X_*, \mathcal{X}_*, C_* \rangle$ -based rationalizability in terms of an ordering for some class of equivalence relations $\{\sim_x\}_{x \in X}$. This, by itself, is, however, of little intuitive interest unless the equivalence class $\{\sim_x\}_{x \in X}$ underlying the $\langle X_*, \mathcal{X}_*, C_* \rangle$ -based rationalizability of C is “induced” by some intuitively plausible menu-dependent criteria. Before concluding this section, we indicate briefly how the case of menu-dependent information can be handled by a variant of the modeling strategy discussed above. For convenience in exposition, we concentrate on Example 3.3. Here the choice of a dish can be intuitively thought of as being associated with an uncertain prospect; for some dishes, the uncertain prospects may be trivial (i.e., they may really be certain prospects), but for others, such as steak, the uncertain prospect is non-trivial. The uncertainty involved may be probabilistic (for example, the uncertain prospect may be a lottery with probability p for getting high quality steak and probability $1 - p$ for getting low quality steak) or non-probabilistic. The important point is that the uncertain prospect, however conceived, that is associated with the choice of a dish, such as steak, can change, depending on the menu from which the option is chosen. Thus, assuming for the moment that the uncertainty involved is probabilistic, the agent’s (subjective) probability for high quality steak can go up when he learns that the menu also includes frogs’ legs and fried snail. Given this, for all $x \in X$, we can now introduce an equivalence relation \sim_x over Z_x with the following interpretation: $(x, A) \sim_x (x, B)$ means that the uncertain prospect that the agent associates with x when the menu is A is the same as the uncertain prospect that the agent associates with x when the menu is B . We can then suitably transform the original description of the agent into a new description, where the equivalence classes, $E[x, A], E[y, B]$, etc., constitute the re-specified options (one can think of a different interpretation of \sim_x , under which the specification of the new options as $(x, E[x, A]), (y, E[y, B])$, etc., would make sense, but we find the interpretation of \sim_x given above more direct and natural).

⁷ We are grateful to a referee for this observation.

5. Some alternative reformulations

As we mentioned earlier, faced with the violation of internal consistency conditions in situations involving menu-dependent criteria, a typical response of theorists is to reformulate some or all the characterizing features, including the universal set of alternatives, the set of potential menus, and the choice function, of the agent in such a way that, such violation no longer occurs in the new formulation. In what follows, we consider a few alternative strategies for such reformulation to be found in the existing literature.⁸

5.1. Re-specification of the set of potential menus

In an interesting paper, Bossert and Suzumura (2009a) present a formulation that re-constructs the set of potential menus. They start with Example 3.1 due to Sen, where the “anomalous” choice behavior of the agent arises from the agent’s concern about a menu-dependent criterion. Following the terminology of Sen (1993), Bossert and Suzumura call such menu-dependent criteria “external norms” and suggest a formal device through which external norms can be incorporated in the model.⁹

Without going into the details of Bossert and Suzumura’s analysis, we outline here the intuition underlying their framework with specific reference to Example 3.1. In Example 3.1, the violation of Chernoff’s condition occurs in a framework where the agent i is described by $\langle X, \mathcal{X}, C \rangle$, such that the universal set of options, X , is the set of all possible fruits, and the class of potential menus, \mathcal{X} , is the class of alternative sets of fruits that the agent may have to choose from. The menu-dependent criterion or external norm involved in Example 3.1 happens to be the social norm that forbids the agent to choose a fruit if it is the only fruit of its type in the menu. Essentially, the analysis of Bossert and Suzumura can be interpreted as a transformation of the original description, $\langle X, \mathcal{X}, C \rangle$, of the agent into another description where the universal set of options continues to be X , but the set of potential menus and the

⁸ We focus on responses that are based on various notions of rationalizability in terms of a single ordering. See Kalai, Rubinstein and Spiegler (2002) for a response based on rationalizability by multiple orderings.

⁹ In a related paper, Bossert and Suzumura (2009b) discuss a framework developed in Bossert (2001) dealing with issues raised by Examples 3.3 and 3.4. The essence of this framework is to re-specify the options as uncertain prospects in a setting of non-probabilistic uncertainty and then to reconstruct the menus in terms of the newly specified options. Given such re-specified options and menus, the violation of Chernoff’s condition disappears.

choice function are re-specified. The main components of their analysis can be described as follows¹⁰.

(i) First, the external norms are formally introduced as a function, g , which, for every $A \in \mathcal{X}$, specifies exactly one (possibly empty) subset $g(A)$ of A , $g(A)$ being interpreted as the set of options in A , which the external norms forbid the agent to choose from A . It is assumed that, for all $A \in \mathcal{X}$, $A - g(A)$ is non-empty.

(ii) Next, one identifies a triple $\langle X_+, \mathcal{X}_+, C_+ \rangle$, such that

$$X_+ = X; \tag{5.1}$$

$$\mathcal{X}_+ \text{ is the set of all non-empty subsets } A_+ \text{ of } X_+, \text{ such that, for some } A \in \mathcal{X}, A_+ = (A - g(A)); \tag{5.2}$$

and

$$C_+ \text{ is a function, which, for every } A_+ \in \mathcal{X}_+, \text{ specifies a non-empty subset } C_+(A_+) \text{ of } A_+, \text{ such that } C_+(A_+) = C(A); \tag{5.3}$$

It can be checked that a triple $\langle X_+, \mathcal{X}_+, C_+ \rangle$ satisfying (5.1), (5.2), and (5.3) will exist if and only if the following two conditions, (5.4) and (5.5), hold:

$$\text{for all } A \in \mathcal{X}, C(A) \subseteq A - g(A) \tag{5.4}$$

$$\text{for all } A, B \in \mathcal{X}, \text{ if } (A - g(A)) = (B - g(B)), \text{ then } C(A) = C(B). \tag{5.5}$$

Further, it can also be checked that there cannot exist more than one triple $\langle X_+, \mathcal{X}_+, C_+ \rangle$ satisfying (5.1), (5.2), and (5.3).

(iii) Finally, one introduces the notion of “norm-conditional” consistency: for every consistency condition σ , one says that the choice function C figuring in the original description, $\langle X, \mathcal{X}, C \rangle$, of the agent *satisfies* σ *subject to the constraints imposed by the menu-dependent criteria or external norms* represented by g if and only if there exists a triple $\langle X_+, \mathcal{X}_+, C_+ \rangle$ satisfying (5.1), (5.2), and (5.3), such that C_+ satisfies σ .

¹⁰ Though we have not strictly adhered to the notation and terminology of Bossert and Suzumura, we believe that, in the following account, we have not departed from their basic intuition

Thus, intuitively, one constructs another description of the agent, such that, for every possible menu A in the initial description, the set of options that the agent chooses from A in the initial description is the set of options that the agent chooses from the menu $(A - g(A))$ in the new description. If the choice function in the original description violates the internal consistency condition σ , but the choice function in the new description satisfies σ , we can say that, though the agent described by $\langle X, \mathcal{X}, C \rangle$, may be violating σ , the violation is due to the fact that, given a menu, he treats the options forbidden by the external norms as “inadmissible for choice under the external norms”, and, that when the menus are re-specified to take into account such norm-based inadmissibility in addition to physical infeasibility, the violation of σ disappears in the re-specified choice problem.

It may be noted the framework proposed by Bossert and Suzumura (2009a) is a special case of our general framework in the following sense. Suppose we have an initial description, $\langle X, \mathcal{X}, C \rangle$, of the agent and a menu-dependent criterion or external norm represented by a function g as as described earlier. Suppose, for every $x \in X$, \sim_x is an equivalence relation defined over Z_x , such that, for all $(x, A), (x, B) \in Z_x$, $(x, B) \sim_x (x, A)$ iff either $x \in (A - g(A)) \cap (B - g(B))$ or $x \in (g(A) \cap g(B))$. Then,

for every internal consistency condition σ , if C satisfies σ subject to the constraints imposed by the menu-dependent criterion represented by g , then there must exist a triple $\langle X_*, \mathcal{X}_*, C_* \rangle$ satisfying (4.1), (4.2), and (4.3), such that C_* satisfies σ ; (5.6)

and

the converse of (5.6) is not necessarily true. (5.7)

The proof of (5.6) is straightforward. To see that (5.7) is true, an example will suffice. In the spirit of Sen’s example involving the choice of a fruit in a party, let the initial description, $\langle X, \mathcal{X}, C \rangle$, of the agent be such that $X = \{x_1, x_2, y_1, y_2, z\}$, where x_1 and x_2 are two apples, y_1 and y_2 are two pears, and z is a mango; $\mathcal{X} = \{A, B, G, H\}$, where $A = \{x_1, x_2, y_1\}$, $B = \{x_2, y_1, y_2\}$, $G = \{y_1, y_2, z\}$, and $H = \{x_1, x_2, z\}$; and $[C(A) = \{x_1, x_2\}, C(B) = \{y_1, y_2\},$ and $C(G) = C(H) = \{z\}]$. Let the menu-dependent criterion be the norm of not choosing from

a set of fruits the last fruit of its type, so that $g(A) = \{y_1\}$, $g(B) = \{x_2\}$, and $g(G) = g(H) = \{z\}$. Let σ be Chernoff's condition. It is clear that, by definition, C cannot satisfy Chernoff's condition subject to the constraints imposed by external norm represented by g since, given $[C(G) = g(G)]$ and $[C(H) = g(H)]$, (5.4) is violated and, hence, no triple $\langle X_+, \mathcal{X}_+, C_+ \rangle$ can possibly satisfy (5.1), (5.2), and (5.3) simultaneously. It is, however, easy to check that there exists a triple $\langle X_*, \mathcal{X}_*, C_* \rangle$ satisfying (4.1), (4.2), and (4.3), such that C_* satisfies Chernoff's condition.

5.2. Re-specification of options to make the menu a part of the description of an option

Another way of handling the phenomenon of menu-dependent criteria and menu-dependent information may be to redefine the options so as to make the menu itself a part of the description of the newly defined options or alternatives¹¹. For example, in Example 3.1, one can redefine the options so that the newly defined option is the act of choosing a particular fruit from a given fruit tray. Once this is done, the options are "choosing an apple from a fruit tray that has one apple and ten pears", "choosing an apple from a fruit tray that has ten pears and two apples", and so on. Thus, if the original description of the agent is $\langle X, \mathcal{X}, C \rangle$, the respecified description will be $\langle X_0, \mathcal{X}_0, C_0 \rangle$, where

X_0 is the set of all (x, A) such that $A \in \mathcal{X}$ and $x \in A$;

\mathcal{X}_0 is the class of all non-empty subsets A_0 of X_0 such that, for some $A \in \mathcal{X}$, $A_0 = A \times \{A\}$; and

C_0 is a choice function, such that, for every $A_0 \in \mathcal{X}_0$, $C_0(A_0) = C(A) \times \{A\}$, where A is the element of \mathcal{X} such that $A_0 = A \times \{A\}$.

It can be checked that, in this reformulation, of the original description of the agent, the choice function C_0 cannot possibly violate any of the consistency conditions introduced in

¹¹ One of us vaguely recalls having read a long time ago an interesting unpublished paper of the late Stig Kanger that discussed such a reformulation of the problem. We have not been able to locate the paper to check the details. See also Suzumura and Xu (2001) for defining an option in a similar fashion.

Definition 2.1. In the case of Cheronff's condition, this is obvious because there do not exist distinct $A_0, B_0 \in \mathcal{X}_0$ such that A_0 is a subset of B_0 . C_0 also cannot violate the weak axiom of revealed preference or the congruence axiom or rationalizability in terms of an ordering, though the reason here is a little less obvious than the reason in the case of Chernoff's condition. Thus, if we follow this method of transforming the original description of the agent, then we will eliminate the problem of the violation of the internal consistency condition, but then the conditions will cease to be of interest in the reformulated version since their violation will become a logical impossibility. The formulation discussed in this subsection can be seen to be, formally, a special case of our general formulation of Section 4, when for all $x \in X$, we define \sim_x in the following way: for all distinct $A, B \in \mathcal{X}$ such that $x \in A$ and $x \in B$, $(x, A) \sim_x (x, A)$ and not $[(x, A) \sim_x (x, B)]$.

5.3. Re-specification of the notion of rationalizability of a choice function

Another possible response to the examples by Luce and Raiffa, and Sen is to retain the original choice problem but to use different notions of rationalizability to accommodate the behavior illustrated by the examples. An early contribution that modifies the standard notion of rationalizability to accommodate Sen's example is by Baigent and Gaertner (1996). In their approach, they develop a notion of rationalizability according to which there exists an ordering \succsim over the universal set of options, such that, if there are several \succsim -greatest elements in a given menu, then the choice set for the given menu is given by the set of all \succsim -greatest elements in the menu, and if there is exactly one \succsim -greatest element in the menu, then the choice set is given by the set of all \succsim -greatest elements in the set of options that is left after excluding from the given menu the unique \succsim -greatest element there. In their approach, the external reference /motivation/social norm is taken into account in the formulation explicitly. As a consequence, the framework developed by Baigent and Gaertner (1996) is specific to the example due to Sen (1993). In a latter contribution along the line of retaining the original choice problem but with a different notion of rationalizability, Gaertner and Xu (1999a) consider the choice of the median option(s) according to a linear ordering over the universal

set. Gaertner and Xu (1997, 1999b), Baigent (2007) and Xu (2007) consider variants of different notions of (non-standard) rationalizability introduced in Baigent and Gaertner (1996), and Gaertner and Xu (1999a) for the original choice problem. Again, these non-standard notions of rationalizability are specific to particular choice behaviors as the axiomatic structures in their framework are designed to handle the respective choice behaviors. In a related contribution, Gaertner and Xu (2004) develop a notion of rationalizability of choice functions based on the idea that, sometimes, the agent may refuse to choose any option even if this is the only option available. Thus, in their framework, the choice set of a non-empty feasible set can be empty. This emptiness of the choice set is due to the agent's concern about the procedure of bringing out the feasible set under consideration: from the agent's perspective, the procedure that brought about the feasible set is so "undesirable" that only a show of protest in the form of the refusal to choose any option from the feasible set is justifiable. For example, when there are several newspapers available in a country, an agent is observed to choose the one that is published by the government (the official newspaper); however, when the government bans all other newspapers except the official one and the other which is fairly pro government, the agent is observed to choose not to read any newspaper. The agent's behavior clearly violates Chernoff's condition, and yet is quite reasonable under the circumstances.

The above notions of non-standard rationalizability of choice functions can be reframed under the formulation presented in Section 4 so that they all become special cases of $\langle X_*, \mathcal{X}_*, C_* \rangle$ -based rationalizability for suitable choice problems with properly chosen equivalence relations. For example, for the choice of the median, one can introduce the notion of indistinguishability as follows: (x, A) is indistinguishable from (x, B) if and only if, according to some criteria, the agent regards x as the median element of each of the two sets, A and B .

6. A reassessment of Sen's argument

In Section 4, we have developed a rather general framework in which the choice problems are reformulated to encompass issues relating to menu-based criteria without making many of the assumptions that are typically made in the existing approaches discussed in Section 5. What, however, is the relevance of our reconstruction in Section 4, as well as the

reconstructions discussed in Section 5, for Sen's criticism of the interpretation of internal consistency conditions as rationality properties that can stand on their own without any reference to the objectives of the agent under consideration? We now take up this issue and we reach a conclusion very different from that often reached in the existing literature.

It seems to us that, while our reformulation of the type of choice problems illustrated in Examples 3.1 through 3.4 as well as other reformulations including that of Bossert and Suzumura (2009a, b) are of interest, they do not address the central problem that Sen raised; nor do they reduce in any way the impact of Sen's criticism of the status the internal consistency conditions have sometimes been accorded in the literature on the theory of revealed preference. To see this, consider again the contention of Sen in this context. For convenience, we concentrate on Example 3.1, though the discussion can be readily extended to all the other examples in Section 3. At the risk of being over-elaborate, let us spell out explicitly the different strands of Sen's reasoning.

Let $\langle X, \mathcal{X}, C \rangle$ be the initial description of the agent, where the universal set of options, X , is simply the set of all possible fruits. Sen's argument then seems to proceed in three distinct steps. The first step consists of the observation that, when we characterize the agent in terms of $\langle X, \mathcal{X}, C \rangle$, the agent's choice function C violates Chernoff's condition. The second step consists of the observation that, when we know that, not only does the agent care about the fruit that he eats, but he also cares about the social norms under consideration, his choice behavior with respect to fruits does not seem irrational or bizarre at all. The third step consists of the conclusion that Sen draws from the two observations. The conclusion is that the appeal of Chernoff's condition as a property of rational choice in the choice problem described by $\langle X, \mathcal{X}, C \rangle$ depends on our information about the objectives or motives of the agent: if we are not aware that, not only does the agent care about what fruit he eats, but he also cares about conforming to certain social norms about the choice of fruits in a party, then, given the information that we have, the violation of Chernoff's condition would seem to us to be an indication of "irrational" choice; on the other hand, if we know that the agent cares about the social norms under consideration in addition to caring about what fruit he eats, then the agent

would seem reasonable to us despite the observed violation of Chernoff's condition by the choice function C .

Now consider what our analysis in Section 4 above shows. What it shows is that, if the theorist modeling the agent's choice behavior knows that the agent cares about the social norm, in addition to caring about what fruit he (i.e. the agent) eats, then the theorist can plausibly transform the description given by $\langle X, \mathcal{X}, C \rangle$ into another description $\langle X_*, \mathcal{X}_*, C_* \rangle$ where C_* satisfies Chernoff's condition. While this is of interest, does it intuitively contradict in any way Sen's conclusion? We do not think so. Indeed, it seems to us that our analysis only serves to reinforce the point that Sen is making. It is true that, if the theorist knows about the agent's concern about social norms, he can plausibly transform the original description of the agent so as to get rid of the problem of violation of Chernoff's condition in the reformulated description. But such a plausible formal transformation of the original description will be possible only if the theorist knows that the agent cares about certain social norms and also knows what these norms are (this latter piece of information is necessary for the theorist to decide whether the choice of an option x from a set A is, in terms of the social norms the agent cares about, distinguishable from the choice of x from another set B). The decision between the alternative formulations, $\langle X, \mathcal{X}, C \rangle$ and $\langle X_*, \mathcal{X}_*, C_* \rangle$, itself will depend on the theorist's information and beliefs about the objectives or motivations of the agent. If we do not know anything about the relevance of social norms for the situation described in Example 3.1, then there is no way of formulating the choice problem in terms of $\langle X_*, \mathcal{X}_*, C_* \rangle$. Then we would presumably formulate the choice problem in terms $\langle X, \mathcal{X}, C \rangle$, and, in that case, the agent's behavior would seem to violate Chernoff's condition. What Sen's analysis emphasizes is the importance of our information about the agent's concerns in assessing the intuitive appeal of internal consistency condition as criteria for "rational choice" in any given model of choice. What our analysis demonstrates is that, given suitable information about the agent's concerns, it may be possible to reformulate the choice problem plausibly in such a way that an internal consistency condition will be satisfied in the reformulated version though it was violated in the original formulation. But, of course, the very possibility of such reformulation will depend on our information and/or belief about the agent's concerns. The issue can be stated slightly

differently. One can distinguish between two distinct aspects of the intuitive notion of rationality. The first is the rationality of an agent's goals (*goal rationality*). For example, it is possible to argue that the agent has irrational goals if, other things remaining the same, the agent would choose to torture more of the animals around him. In general, positive economics has scrupulously avoided the issue of goal rationality. It has exclusively focused on what may be called *structural rationality*, i.e., the issue of whether the choices that the agent makes are coherent given the goals that the agent has. It is this notion of coherence of choice, given the goals of the agent that the internal consistency conditions are intended to capture. What Sen's argument shows is that, even when we identify the notion of rational choice with this limited notion of structural rationality or coherence of choices given whatever goals the agent may have, what constitutes coherent choice given one set of goals may not be coherent for a different set of goals. Therefore, whether or not the agent is being coherent in his choices would depend crucially on our intuition about what constitute the goals of the agent. Where do the agent's goals enter into our formal models of an agent's choices? Note that before we can even formally define the internal consistency conditions, we have to describe the choice situation, namely the universal set of options, the class of opportunity sets that the agents may choose from, and the notion of the agent's choice function. The very first step here is, of course, to specify the universal set of options which embodies our conception of the type of objects that the agent is really concerned with¹². If the universal set of options is specified as eating a mango, eating an apple, ..., then implicitly we are taking the view that the agent is concerned only with what fruit he eats. If in a model of choice specified in this fashion, the agent's choices violate Chernoff's condition, then it may be because the options as we have specified them (in the course of specifying the universal set which reflects the goals of the agent) completely and correctly capture what the agent cares about, but the choices of the agent are incoherent given the agent's concerns and goals, or it may be because we have specified the options in a way that does not reflect the concerns of the agent appropriately. Therefore, even when we limit ourselves, as we typically do in positive economics, to the notion of structural rationality as the only conception of rationality, whether the choice behavior of an

¹² Cf. Dasgupta, Kumar, and Pattanaik (2000).

agent is structurally irrational (i.e., incoherent, given the agent's goals) cannot be decided independently of what we consider to be the goals or objectives of the agent. It seems to us that Sen's criticism of the view of internal consistency conditions as properties of rational choice that can stand on their own without any reference to the agent's concerns is valid in a fundamental sense and no formal reconstruction of the agent's description detracts from its impact in any way. Thus, our assessment of Sen's arguments regarding the status of internal consistency conditions as properties of rational choice is very different from that of Bossert and Suzumura (2009a) who, after demonstrating that some of Sen's examples can be accommodated in their modified version of the conventional framework¹³, conclude that their analysis "builds a bridge between rationalizability theory and Sen's criticism" and that what emerges from their analysis is "the possibility of a peaceful coexistence of a norm-conditional rationalizability theory and Sen's elaborate criticism against the internal consistency of choice."

We would like to clarify three other related points. First, note that so far we have taken a normative interpretation of the internal consistency conditions by treating them as conditions that a *rational* individual's choice behavior will satisfy. Sen focused on this interpretation which is often adopted in the literature. What if we treat the internal consistency conditions as testable empirical hypotheses regarding an agent's choice behaviour? It is easy to see that the problem to which Sen drew our attention in the context of the normative interpretation of internal consistency conditions arises again, though in a somewhat different form, when we treat those conditions as empirically testable hypotheses. We can introduce the internal consistency conditions only after we specify the universal set of options, i.e., only after we commit ourselves to a particular view of the alternatives that the agent chooses. If, given a particular specification of the choice problem, the choice function of the agent turns out to violate some internal consistency condition, say Chernoff's condition, then such violation falsifies the conjunction of two hypotheses. The first hypothesis is that our specification of the universal set of options correctly embodies what the agent is concerned with in making his choices and the second hypothesis is that the agent's choice function satisfies Chernoff's

¹³ To be more specific, Bossert and Suzumura (2009a) are concerned with the conventional framework of the theory of revealed preference.

condition when the options are specified in a way that correctly captures the agent's goals. Given the falsification of the conjunction of these two hypotheses (i.e., given that the choice function figuring in a given description of the agent violates Chernoff's condition), we cannot decide whether to reject the second hypothesis without committing ourselves to a position about whether or not the options, as we have specified them in our formal model, capture the objectives of the agent.¹⁴

The second point is this. Sen's original argument was formulated with reference to the theory of revealed preference where we start with the primitive concept of choice rather than preference. What happens if we start with the primitive notion of preference and formulate, as usual, the notion of structural rationality in terms of the requirement that the agent's preferences be an ordering, that is, the requirements that the agent's preferences satisfy reflexivity, connectedness, and transitivity? It is easy to see that this would make little difference to the validity or impact of the basic point of Sen. Again, before we can even introduce the notion of the agent's preferences, we need to specify the universal set of options over which the preferences are to be defined. If the preferences violate, say, transitivity¹⁵, then again we have to face the problem of deciding whether, given our chosen formulation of the choice problem, the requirement of transitivity has much appeal in light of what we know about the agent's goals.

Finally, we consider a point that sometimes comes up in the context of Sen's critique of the treatment of internal consistency conditions as conditions for rational choice. It is sometimes argued that: (1) the theory of revealed preference and the associated internal consistency conditions for choice were never intended to be applied to situations involving menu-dependent criteria or menu-dependent information; and (2) that there has been an implicit understanding among revealed preference theorists that the scope of the theory must

¹⁴ See Dasgupta, Kumar, and Pattanaik (2000). See Quine (1953) on methodological issues relating to the testing of joint hypotheses.

¹⁵ The question may arise how we conclude that transitivity of preferences are violated. If one believes that preferences are non-observable, then the violation of transitivity is to be inferred by: (i) postulating some relation between the agent's preferences and the choice(s) of the agent from different opportunity sets; and (ii) asking whether, given the postulated relation between the agent's preferences and his choices from opportunity sets, the observed choices are compatible with the requirement that preferences be transitive.

be restricted to exclude such situations. Whether revealed preference theorists, such as Samuelson (1947, 1948), Little (1949), Houthakker (1950), and Richter (1966) had in mind such a scope-restricted theory of revealed preference is an interesting issue in the history of economic thought, but it is beyond the scope of our paper. What, however, is germane for the purpose of this paper is the implications, for Sen's critique, of explicitly restricting the applications of internal consistency conditions, as properties of rational choice, to situations where neither the criteria for choice nor the information relevant for choice are menu-dependent. For convenience of exposition, let us focus on Chernoff's condition. What the proposed restriction of the applicability of Chernoff's condition as a criterion of rationality of choice essentially does is to replace the intuitive position represented by (6.1) below by the intuitive position represented by (6.2):

an agent, whose choice function violates Chernoff's condition, is not rational (6.1)

if the choice situation does not involve any menu-dependent criteria or menu-dependent information, then an agent, whose choice function violates Chernoff's condition, is not rational. (6.2)

Though the examples in Section 3 can be used as intuitive counterexamples against the position represented by (6.1), clearly they cannot be used in that fashion against the position represented by (6.2) since all those examples involve either menu-dependent criteria or menu-dependent information. Does this in any way work against the substance of Sen's argument that, without referring to an agent's objectives and concerns, one cannot treat the internal consistency conditions for choice, on their own, as tests of the rationality of the agent's choices? We do not think so. Suppose we take position (6.2) and we find that the agent's choices violate Chernoff's condition. Then we cannot say anything about the rationality of the agent's choices unless we commit ourselves to a position about whether the agent's choice situation involves menu-dependent criteria or menu-dependent information relevant for the agent, and, of course, we cannot take a position about whether the agent's choice situation involves menu-dependent criteria or menu-dependent information without considering what

the agent's goals/objectives/ concerns may be. We are then back to the core of Sen's argument, namely, that without considering the objectives and concerns of the agent, one cannot say much about the rationality of the agent's choices exclusively on the basis of internal consistency conditions.

We have considered above the proposal to restrict the application of internal consistency conditions for choice, when they are interpreted as conditions of rationality. Exactly similar reasoning can, however, be given if, interpreting the internal consistency conditions as empirically testable hypotheses, we replace hypothesis (6.3) below by hypothesis (6.4):

the agent's choice behavior satisfies Chernoff's conditions (6.3)

if the choice situation does not involve menu-dependent criteria or menu-dependent information, then the agent's choice behavior satisfies Chernoff's condition. (6.4)

7. Conclusions

In this paper, we have formulated a more general framework than those suggested in the literature to accommodate the counter-examples due to Luce and Raiffa and Sen. We have also argued that, though our formulation, as well as those in the existing literature, is of interest for certain purposes, it does not in any way affect either the validity or the conceptual impact of Sen's contention that the reasonableness of internal consistency conditions as conditions for rational choice cannot be judged without going into the agent's motives and objectives. Our conclusion here differs significantly from the position taken by Bossert and Suzumura (2009a, b) vis-à-vis Sen's analysis in their important recent contribution.

We believe that Sen's basic point has important implications for the classical economic theory of rational choice. The classical economic theory of rational choice has focused almost exclusively on structural rationality as distinct from goal rationality. Structural rationality itself, however, embodies the notion of coherent choice, *given the agent's goals and concerns*. It is, therefore, not possible to conclude whether or not the agent satisfies structural rationality simply on the basis of our observations of the agent's choice behavior without referring to the

concerns of the agent. Choice behavior that may appear incoherent for some set of concerns, may be perfectly coherent for another set of concerns. In one sense, it is not even possible to construct a formal model of rational choice without introducing some presupposition, whether explicit or implicit, about the agent's concerns. In formal models of rational choice, the specification of the options captures our assumption, often implicit, regarding the concerns of the agent. The examples of menu-dependent criteria and information given by Luce and Raiffa and Sen are important reminders that, when, in the framework of our formal model, the agent's choices violate internal consistency conditions, such violation cannot be taken as a definite indication of structurally incoherent choice; instead, it may be simply due to the fact that the specifications of options in our formal model does not capture certain concerns that the agent has. This, of course, raises the question whether an outside observer, say, an economist, observing an agent's choice behavior, can ever be certain whether, given the goals of the agent, he is behaving in an incoherent fashion. The answer to this question would seem to be in the negative for the following reason. In general, there can be an infinite number of different goals and concerns guiding the agent's choices. No matter how carefully the economist may specify the options, there will still remain the possibility that his specification of the options does not capture some concerns of the agent and the seeming incoherence is due to that. The best that the economist can say is that, if the information that he has about the agent's concerns and that he has put into his conception of an option is correct and complete, then the agent's choice behavior is incoherent. This tentative position would seem to be more justifiable than the position that internal inconsistency of the agent's observed choice behavior (choice being seen in terms of the observer's conception of the agent's "options") is a conclusive indicator of "irrationality", as well as the position that, if the observed choice behavior of the agent violates internal consistency, then there must be some concerns of the agent that are not captured by the specification of the options, and the internal inconsistency will disappear once such concerns are incorporated in the specification of options.

Appendix

Proof of Proposition 4.1. Let $\langle X, \mathcal{X}, C \rangle$ be the initial description of the agent, and, given \sim_x for every $x \in X$, let $\langle X_*, \mathcal{X}_*, C_* \rangle$ be the modified description satisfying (4.1), (4.2), and (4.3).

(i)

Chernoff's condition. Suppose the choice function C satisfies Chernoff's condition. Let $A_*, B_* \in \mathcal{X}_*$ and $x_*, y_* \in X_*$ be such that $x_*, y_* \in A_* \subseteq B_*$ and $x_* \in C_*(A_*)$ but $y_* \notin C_*(A_*)$. We need to show that $y_* \notin C_*(B_*)$. From the definition of \mathcal{X}_* , there exists $B \in \mathcal{X}$, such that $B_* = \{(b, E[b, B]): b \in B\}$. Since $A_* \subseteq B_*$, it must be the case that, for some $A \in \mathcal{X}$ with $A \subseteq B$, $A_* = \{(a, E[a, A]): a \in A\}$. Since $x_*, y_* \in A_*$, there must be $a', b' \in A$ such that $x_* = (a', E[a', A])$ and $y_* = (b', E[a', A])$. Note that $x_* \in C_*(A_*)$ but $y_* \notin C_*(A_*)$. It must be true that $a' \in C(A)$ and $b' \notin C(A)$. Since C satisfies Chernoff's condition, from $A \subseteq B$, and $a' \in C(A)$ and $b' \notin C(A)$, we must have $b' \notin C(B)$. Therefore, by the definition of C_* , we obtain $y_* = (b', E[a', A]) \notin C_*(B_*)$.

The weak axiom of revealed preference. Suppose the choice function C satisfies the weak axiom of revealed preference. Let $A_*, B_* \in \mathcal{X}_*$ and $x_*, y_* \in X_*$ be such that $x_*, y_* \in A_* \cap B_*$ and $x_* \in C_*(A_*)$. We need to show not($y_* \in C_*(B_*)$ and $x_* \notin C_*(B_*)$). From the definition of \mathcal{X}_* , there must be some $A, B \in \mathcal{X}$, such that $A_* = \{(a, E[a, A]): a \in A\}$ and $B_* = \{(b, E[b, B]): b \in B\}$. Since $x_*, y_* \in A_* \cap B_*$, there must be $x, y \in A \cap B$ such that $x_* = (x, E[x, A]) = (x, E[x, B])$ and $y_* = (y, E[y, A]) = (y, E[y, B])$. Suppose $x_* \in C_*(A_*)$, and suppose to the contrary that $y_* \in C_*(B_*)$ and $x_* \notin C_*(B_*)$. Then, we must have $x \in C(A)$, $y \in C(B)$ and $x \notin C(B)$. This contradicts our assumption that the choice function C satisfies

the weak axiom of revealed preference. Therefore, $\text{not}(y_* \in C_*(B_*) \text{ and } x_* \notin C_*(B_*))$ holds, showing that the choice function C_* satisfies the weak axiom of revealed preference.

The congruence axiom and rationalizability in terms of an ordering. It is fairly easy to see that, when the choice function C is rationalizable in terms of an ordering, the choice function C_* must be rationalizable in terms of an ordering as well. Given that the congruence axiom for C is logically equivalent to rationalizability of C in terms of an ordering, and that the congruence axiom for C_* is logically equivalent to rationalizability of C_* in terms of an ordering, it follows that if C satisfies the congruence axiom, then C_* satisfies the congruence axiom.

(ii) Since the congruence axiom and rationalizability in terms of an ordering are logically equivalent and both these properties are strictly stronger than the weak axiom of revealed preference, as well as Chernoff's condition, it will be enough if we show that C_* satisfies the congruence axiom when \sim_x is trivial for all $x \in X$. Suppose, for all $x \in X$, \sim_x is trivial but C_* violates the congruence axiom. We shall show a contradiction. Since, by our assumption, C_* violates the congruence axiom,

there exist a positive integer n , menus $A_{*1} \dots, A_{*n+1} \in \mathcal{X}_*$, and $x_{*1}, \dots, x_{*n+1} \in X_*$, such that, for all $t \in \{1, \dots, n+1\}$, $x_{*t} \in C_*(A_{*t})$; for all $t \in \{1, 2, \dots, n\}$, $x_{*t+1} \in A_{*t}$; and

$$x_{*1} \in (A_{*n+1} - C_*(A_{*n+1})). \quad (\text{A.1})$$

In what follows, we shall treat such $A_{*1} \dots, A_{*n+1}$ and x_{*1}, \dots, x_{*n+1} as fixed. Given the construction of $\langle X_*, \mathcal{X}_*, C_* \rangle$, for every $t \in \{1, 2, \dots, n+1\}$, there exists a unique $A_t \in \mathcal{X}$, such that

$$A_{*t} = \{(x, E[x, A_t]): x \in A_t\} \quad (\text{A.2})$$

and

$$\text{for all } x_* \in A_{*t}, \text{ there exists a unique } x \in A_t, \text{ such that } x_* = (x, E[x, A_t]). \quad (\text{A.3})$$

By (A.1), for all $t \in \{1, 2, \dots, n\}$, $x_{*t+1} \in A_{*t}$ and $x_{*t+1} \in A_{*t+1}$. Then, by (A.3), for every $t \in \{1, 2, \dots, n\}$, there exists a unique $y_t \in A_t$, such that $x_{*t+1} = (y_t, E[y_t, A_t])$, and there

exists a unique $z_{t+1} \in A_{t+1}$, such that $x_{*t+1} = (z_{t+1}, E[z_{t+1}, A_{t+1}])$. In that case, for every $t \in \{1, 2, \dots, n\}$, we must have $y_t = z_{t+1}$, and, further, given that every \sim_x is trivial for every $x \in X$, we must have $A_t = A_{t+1}$. Since $A_t = A_{t+1}$ for all $t \in \{1, 2, \dots, n\}$, we have $A_1 = A_{n+1}$ and, hence, $A_{*1} = A_{*n+1}$. This however generates a contradiction, given that, by (A.1), $x_{*1} \in C(A_{*1})$ and $x_{*1} \in (A_{*n+1} - C_*(A_{*n+1}))$.

(iii) An example will suffice to prove Proposition 4.1 (iii). Let the initial description $\langle X, \mathcal{X}, C \rangle$ be such that $X = \{a, b, c, d, e\}$; $\mathcal{X} = \{A, B, G, H, K\}$, where $A = \{a, b, c\}$, $B = \{a, c, d\}$, $G = \{a, b, e\}$, $H = \{c, d, e\}$, and $K = \{a, b, c, d\}$; and $C(A) = \{a, b\}$, $C(B) = \{c, d\}$, $C(G) = \{e\}$, $C(H) = \{e\}$, and $C(K) = \{a, b\}$. Assume that the exogenously given set, $\{\sim_x\}_{x \in X}$, of equivalence relations is given by the following:
 $(a, A) \sim_a (a, G) \sim_a (a, K)$, $(b, A) \sim_b (b, G) \sim_b (b, K)$, $(c, B) \sim_c (c, H) \sim_c (c, K)$, $(d, B) \sim_d (d, H) \sim_d (d, K)$, and $(e, G) \sim_e (e, H)$.

It is clear that C violates Chernoff's condition, and, for all $x \in X$, \sim_x is non-trivial. Given $\{\sim_x\}_{x \in X}$, as specified above, consider the new description $\langle X_*, \mathcal{X}_*, C_* \rangle$ of the agent that satisfies conditions (4.1), (4.2), and (4.3). Clearly, $X_* = \{(a, E[a, A]), (b, E[b, A]), (c, E[c, A]), (a, E[a, B]), (c, E[c, B]), (d, E[d, B]), (e, E[e, G])\}$; $\mathcal{X}_* = \{A_*, B_*, G_*, H_*, K_*\}$, where $A_* = \{(a, E[a, A]), ((b, E[b, A]), (c, E[c, A]))\}$, $B_* = \{(a, E[a, B]), (c, E[c, B]), (d, E[d, B])\}$, $G_* = \{(a, E[a, A]), (b, E[b, A]), (e, E[e, G])\}$, $H_* = \{(c, E[c, B]), (d, E[d, B]), (e, E[e, G])\}$, and $K_* = \{(a, E[a, A]), (b, E[b, A]), (c, E[c, B]), (d, E[d, B])\}$; and $C_*(A_*) = \{(a, E[a, A]), (b, E[b, A])\}$, $C_*(B_*) = \{(c, E[c, B]), (d, E[d, B])\}$, $C_*(G_*) = \{(e, E[e, G])\}$, $C_*(H_*) = \{(e, E[e, G])\}$, and $C_*(K_*) = \{(a, E[a, A]), (b, E[b, A])\}$. It can be easily checked that C_* is rationalizable by the following ordering \succsim over \mathcal{X}_* (\simeq and \succ , respectively, denote the symmetric and asymmetric factors of \succsim):

$$(e, E[e, G]) \succ (a, E[a, A]) \simeq (b, E[b, A]) \succ (c, E[c, B]) \simeq (d, E[d, B]) \succ (a, E[a, B]) \simeq (c, E[c, A]).$$

Since C_* satisfies rationalizability in terms of an ordering, it clearly satisfies all the other properties introduced in Definition 2.1. •
