Europe and Central Asia Region Middle East and North Africa Region Population Projections, 1992-93 Edition

My T. Vu
Eduard Bos
and
Ann Levin

Currently, Asia has 59 percent of all people; Europe, 15 percent; America, 14 percent; Africa, 12 percent; and Oceania, 1 percent. Over time, Asia's share is projected to remain fairly stable, but Europe's share will almost be halved and Africa's share more than doubled.

WPS 1016

This paper — a product of the Population, Health, and Nutrition Division and the Population Policy Advisory Service of the Population and Human Resources Department — is part of a larger effort in the department to update demographic indicators on an annual basis. Copies of the paper are available free from the World Bank, 1818 H Street NW, Washington DC 20433. Please contact Otilia Nadora, room S6-065, extension 31091 (November 1992).

Population projections for all countries are prepared annually by the Bank's Population and Human Resources Department. They are published first in summary form in the Bank's *World Development Report* and later in greater detail as technical notes or working papers and, in alternate years, as a book.

Separate papers cover the six Bank regions: (1) Africa (Sub-Saharan), (2) Latin America and the Caribbean (and North America), (3) East Asia and Pacific region and South Asia region combined, and (4) Europe and Central Asia region and Middle East and North Africa region combined.

This year's projections contain two major changes from the previous edition. First, projected mortality from AIDS has been incorporated into the tables for Sub-Saharan African countries. Second, demographic estimates and projections are provided separately for each of the fifteen countries that constituted the former Soviet Union.

Among trends observed:

- The total fertility rate for the world is an estimated 3.2 children per woman in 1992. The highest total fertility rates are found in East and West Africa, where the rate is above 6. Most countries in the Asian and Latin American

regions have moderate fertility of three to five children per woman, although both continents contain countries with very high and very low levels. More developed countries have the lowest fertility, with rates generally ranging between 2.5 and 1.5, but one of the former Soviet republics, Tajikistan, has a total fertility rate of 5.

- Europe (including the former Soviet republics) is the only continent where aggregate fertility is currently below replacement — that is, where women are not having enough children to replace themselves. Recent trends in some countries of Europe show small increases in fertility, and the projections assume that the total fertility rate will recover to replacement level by 2030. Europe is also the continent with the most homogeneous fertility levels: with the exception of four of the former Soviet republics that have total fertility rates above 3, fertility in the other 41 countries varies in a narrow range between 1.5 and 2.8.

- The Northern American region has the highest aggregate life expectancy, 76.7. The European region has the second highest aggregate life expectancy, 74.4. Every country in this region is above the world's average of 66. Moving from west to east through this region, life expectancies tend to decline, from a high of 78 in Iceland to a low of 66 in Turkmenistan.

The Policy Research Working Paper Series disseminates the findings of work under way in the Bank. An objective of the series is to get these findings out quickly, even if presentations are less than fully polished. The findings, interpretations, and conclusions in these papers do not necessarily represent official Bank policy.

FOREWORD

Population projections for all countries are prepared annually by the Population and Human Resources Department of the World Bank. They are published first in summary form in the Bank's *World Development Report* and later in greater detail as technical notes or working papers and, in alternate years, as a book.

Four separate working papers cover the six Bank regions: Africa (Sub-Saharan), Latin America and the Caribbean (and Northern America), East Asia and Pacific region and South Asia region combined, and Europe and Central Asia region and Middle East and North Africa region combined.

This year's projections contain two major changes from the previous edition. First, projected mortality from AIDS has been incorporated in the tables for Sub-Saharan African countries. Second, demographic estimates and projections are provided separately for each of the fifteen countries that constituted the Soviet Union.

We intend these papers to provide convenient and up-to-date references on the likely demographic future of each country. We hope it will facilitate the process of taking population into account in development work.

Thomas W. Merrick
Senior Population Adviser
Population and Human Resources Department

ACKNOWLEDGEMENTS

A number of persons provided us with important information for this work or assisted us in preparing it in other ways. The Estimates and Projections Section of the U.N. Population Division has been continually supportive in providing us with data, even before their publication as U.N. assessments. Partly as a result, nonessential differences between these projections and the biennial U.N. assessments have been minimized. We are grateful to the section chief, Larry Helichman, and to his continually accommodating staff, as well as to the head of the division, Shunichi Inoue, and hope that the collaboration will continue.

World Bank country economists, population specialists, and the few demographers in the operating divisions have also provided us with recent population estimates, bringing to our attention government reports we might not otherwise see.

This exercise was carried out using a personal computer program, ProjPC-II, written by Kenneth Hill of Johns Hopkins University.

This work for this paper was started as part of the Population, Health, and Nutrition Division's work program. The paper was completed as a product of the Population Policy and Advisory Service of the Population and Human Resources Department. We are grateful to the division chief, Dr. Anthony R. Measham, and the department director, Ann O. Hamilton, for their support of this work.

We also wish to acknowledge the interest of the Bank's International Economics Socioeconomic Data Division (IECSE), which not only utilizes our figures--for such important Bank purposes as estimating per capita GNP--and incorporates them into the databases it maintains and publications it distributes but also helps coordinate communications with country economists. Sulekha Patel and Taranjit Kaur of that division have been particularly helpful in the past year.

INTRODUCTION

This paper provides population projections for each country, economy, or territory in the World Bank Europe and Central Asia and Middle East and North Africa Regions, as well as for nonborrower countries in the same geographic area. Three companion papers provide similar projections for the other Bank regions. Each paper also contains projections for the world and for groups of countries for all regions and income groups. The introduction section (similar across the four regional papers) summarizes the main demographic trends and the projection results, discusses the projection methodology, and lists the sources of current population estimates and vital rates.

These projections update those issued in 1991 as the *1990-91 Edition*. This edition returns to the format of earlier editions, showing detailed age-sex distributions from 1985 onwards. This year's projections differ in two important ways from those issued previously. First, mortality from AIDS has been incorporated in countries in Sub-Saharan Africa where there is a measurable level of HIV infection, and has affected the projected population growth in these countries and for Africa as a whole. The procedures for projecting HIV and AIDS and a discussion of the impact of AIDS mortality on demographic indicators are presented as *Special Topic I* following the introduction. Second, as a result of recent political changes in some parts of the world, estimates and projections for several new countries have been added. These new projections cover the fifteen countries that constituted the Soviet Union (see *Special Topic II* below), the combined Germanies and Yemens, and the former Yugoslavian republics of Slovenia and Croatia. The cut-off date for revisions for this edition was April 15, 1992, so that political developments that occurred after that date could not be incorporated. The *Addendum* section following the *Sources* discusses some of these late developments.

Because of changes within the World Bank organizational structure, population projections of regional and country department aggregates are not comparable to those of previous years. New geographical regions have been formed and many of the country departments have changed their composition, partly as a result of the addition of many new borrower countries. For example, Asia has now been split into two separate regions, East Asia and the Pacific and South Asia, each of which has three country departments, rather than the five previous departments under one region. Country departments in the Africa and Latin America regions, while keeping the same name, have also been restructured.

Projection methods have changed only marginally since the previous edition. Essentially, recent country-specific data about levels and trends in fertility, mortality, and international migration are applied to available sex-age distributions in order to obtain short-run projections. Long-run projections, up to 2150, are made under the assumptions that fertility and mortality eventually become stable and net international migration declines to zero. One change in procedures from the previous edition involves a more gradual decline in the total fertility rate during the first period that fertility is projected to decline, followed by a more rapid decline than was previously assumed. This and other details of the methodology are described in the *Data and Methods* section.

Caution is appropriate with all projections like these. They essentially involve working out the implications of assumptions about demographic trends. None of the results should be interpreted as indicating certitude about the future. Instead, they should be read with the universal qualifier that population will follow the indicated path if the assumptions prove to be correct.

OVERVIEW OF TRENDS AND PROJECTIONS

In the following sections, recent demographic trends and projections for the future will be discussed. Overall trends for the world, geographical regions and countries grouped by income level will be reviewed first, followed by a presentation of some notable country results.

Rapid demographic changes are taking place in some parts of the world, while in other parts demographic change is more gradual. Over the past few decades, Southeast Asian and Latin American countries have experienced rapid declines in mortality and fertility, while most Sub-Saharan African and Middle Eastern countries have seen only minor changes, with both mortality and fertility remaining at high levels. The more developed countries of Europe, North America, and Asia are currently also among the gradual changers, having lowered their mortality and fertility earlier. In many of these countries, fertility fluctuates in a narrow range below replacement -- below the level required for each generation to replace itself in the succeeding generation -- and mortality at most ages has reached levels so low that further declines can only be small. The different regional trends, and their implications for future demographic indicators, will now be discussed in greater detail.

World and Regions

Population Growth

The world population for mid-1992 is estimated to be 5.44 billion, an increase of 180 million over the population in mid-1990. By 2000, it is projected to increase to 6.17 billion, an increase of 12 percent over the 1992 estimate, and by 2025 world population is projected to reach 8.34 billion, an increase of 52 percent over this year's population. During 1990 to 1995, population growth rates average 1.7 percent per year, and are projected to decline to 1.2 percent around 2010 and 1.0 percent by 2025. However, the number of persons added each year will still be growing between 1990 and 1995 and is projected to stabilize at just below 90 million. Only after 2025 is the annual increase in population projected to start declining substantially (Figure 1). This combination of declining growth rates with steady increases in population is the result of past high fertility rates, which produced ever-larger cohorts that are now moving through the age-structure, replacing smaller cohorts born earlier. Even though the number of births worldwide is increasing well below overall growth rates, the *population momentum* built into the age structure will ensure high population growth for decades to come.

In 1992, less developed countries (LDCs) comprise 77 percent of the population, while more developed countries (MDCs) cover the other 23 percent. Since annual growth rates are significantly higher in LDCs, 2.0 percent compared to 0.6 percent for MDCs in 1992, the share of the world population from LDCs is projected to increase. By the beginning of the next century, it will increase to 79 percent, and will reach 83 percent by 2025.

Long-run trends, up to 2150, are constructed by gradually bringing fertility and mortality in harmony, i.e., by setting fertility at a level where each woman replaces herself under projected mortality conditions, and by assuming net international migration to be zero. The result of these assumptions is that the population gradually becomes stationary, with a fixed age structure that is independent of its current age structure and a growth rate of zero. The "ultimate" size of such stationary populations is of interest because it demonstrates the momentum built into populations by current fertility and mortality conditions. The size of the stationary population of the world is projected as 12.2 billion, of which 88 percent would live in countries currently defined as less developed.

Figure 1. Increase in Population
Average annual increase (millions)

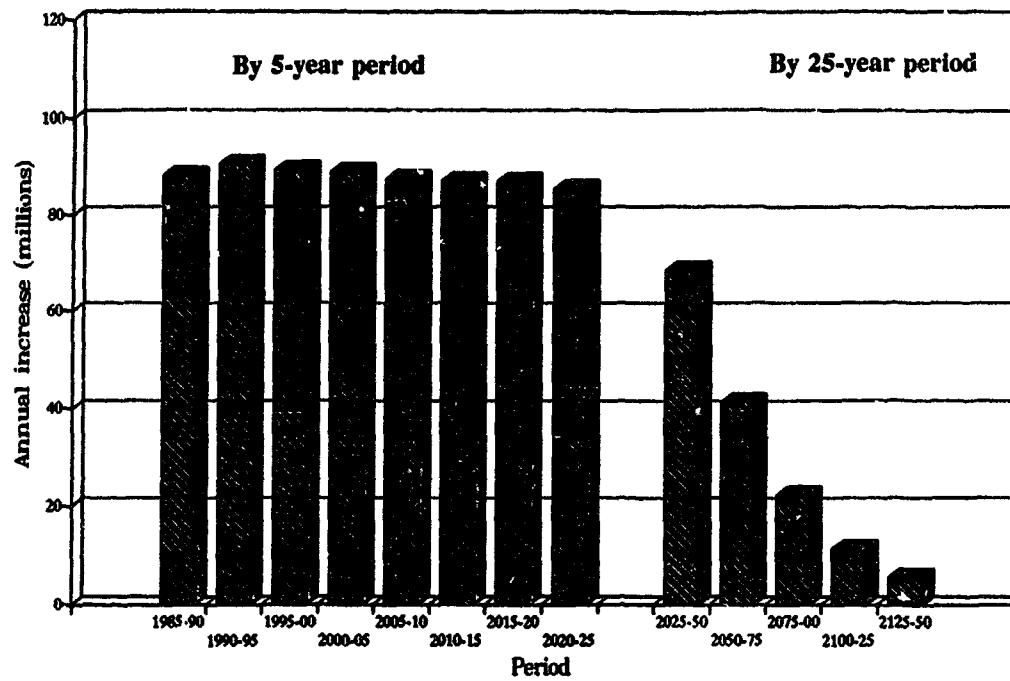

Figure 2. Comparison of Projections
1990-91 Edition and 1992-93 Edition

X INTRODUCTION

How do the projections for the world and for LDCs and MDCs compare with those previously produced? Figure 2 compares this year's projections with the previous set (1990-91). For MDCs, there is no distinguishable difference between the projected populations. In the case of the LDCs projections, this year's projection is, from the early part of the 21st century onward, increasingly below the previous projection. This reflects the impact of AIDS, which increases the number of deaths and reduces the number of births. For the world as a whole, the projections differ to the same extent as the LDC projections differ.

When growth rates for major world regions are compared, striking differences become apparent. The continent with the highest growth rate is Africa with an annual rate of 2.9 percent in the early 1990s, about six times the 0.5 percent annual growth rate of Europe (which includes the former U.S.S.R. countries). Growth rates in the Americas, in Asia, and in Oceania are intermediate; at 1.5, 1.8, and 1.6 percent, respectively, they are close to the world's average. At these growth rates, the population of Africa would double in approximately 25 years, while Europe would double in 140 years.

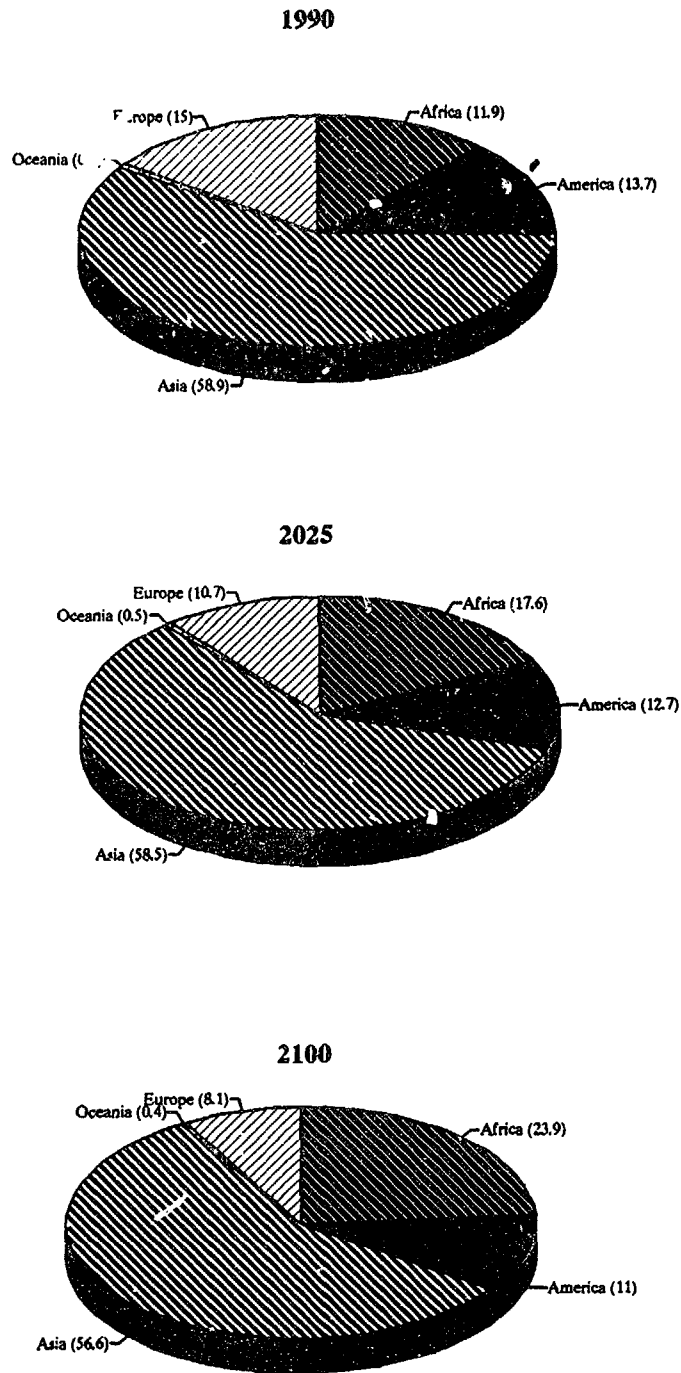

One of the consequences of such large differences in population growth rates is a changing distribution of the population over the continents. Currently, Asia has 59 percent of all people; Europe, 15 percent; America, 14 percent, Africa, 12 percent, and Oceania, 1 percent. Over time, Asia's share is projected to remain fairly stable, but Europe's share will almost be halved and Africa's share more than doubled. Figure 3 shows the distribution of the world's population at three different points in time.

Because Asia is so large and diverse, disaggregation of its populations by subregions is more illustrative of the differences in population growth rates. South Asia, which has 1.24 billion people (23 percent of the world population), has an estimated growth rate of 2.0 percent in 1992, while East and Southeast Asia, which include China and contains 1.85 billion people (34 percent of the world population), had a lower rate of 1.4 percent. South Asia is growing annually by 25 million, East and Southeast Asia by 27 million persons. By 2025, the growth rates are projected to decline to 1.1 percent and 0.9 percent, respectively. Even with these lower rates, 23 million people will be added in South Asia each year and 17 million in East and Southeast Asia because of their large projected base populations of 2.05 billion and 2.54 billion. Southwest Asia, which consists mostly of Middle Eastern countries, has a much smaller number of people, 143 million, but is growing at a faster rate than the other two regions, with a growth rate of 2.9 percent in 1992. It is projected to lower its growth rate to 1.6 percent by 2025, but will by then have more than doubled its population to 293 million.

In Africa, more homogeneity is found among the East, West, and North subregions. The fastest growing subregion is East Africa with a growth rate of 3.0 percent in 1992, followed by West Africa with a growth rate of 2.9 percent. North Africa, has begun to lower its growth rate but still has a growth rate of 2.5 percent, which is projected to diminish to 1.3 percent by 2025. Even though East Africa's growth rate is projected to start declining immediately, by 2025 it will still have a growth rate of 1.9 percent, and will add 14 million persons a year. In West Africa, the growth rate is projected to decrease to 1.7 percent in 2025, but will still be adding 9 million persons each year. These differences in growth rates are the outcome of assumed trends in fertility and mortality (discussed below).

Oceania has a growth rate of 1.6 percent in 1992 and is projected to lower its rate to 0.6 percent by 2025. Because of its small population (0.5 percent of the world's total) its impact on world demographic trends is trivial.

Figure 3. Percentage Distribution of World Population by Continent, 1990, 2025, and 2100

xii INTRODUCTION

America is divided into two subregions, North America and Latin America and the Caribbean. In North America, the growth rate is relatively low, 0.9 percent in 1992, and is projected to decline to 0.3 percent by 2025, as net migration from Latin America is assumed to diminish. In Latin America and the Caribbean, the growth rate in 1992 was significantly higher, 1.8 percent, and is projected to decline to 0.9 percent by 2025.

The lowest growth rate for any continent, .5 percent in 1992, is found in the region comprised of Europe and the former Soviet Republics. This rate is projected to decline further to .2 percent by 2025.

Tables 1 and 2 summarize current and projected trends in population growth.

Fertility

The total fertility rate (TFR) for the world is estimated to be 3.2 children per woman in 1992. The highest TFRs are found in East and West Africa, where the TFR is above 6. Most countries in the Asian and Latin American regions have moderate fertility of three to five children per woman, although both continents contain countries with very high and very low levels. MDCs have the lowest fertility, with rates generally ranging between 2.5 and 1.5, but one of the former Soviet Republics, Tajikistan, has a TFR of 5.

World fertility is projected to decline from 3.2 now to 2.9 by the turn of the century and to 2.4 by 2025. These projected trends in fertility are determined from past trends and general assumptions as described in *Data and Methods*. For countries with high fertility, the trend is assumed to be downward, and substantial fertility decline is projected. Countries that have reached below replacement level fertility are assumed to gradually raise their TFRs to replacement.

In East and West Africa, recent trends in fertility are downwards, but only slightly so. Between 1985 and 1992, the TFR has declined from 6.4 to 6.2 in these regions that together constitute Sub-Saharan Africa. Only a few countries have shown sustained decline in fertility, while the majority of countries have had persisted high fertility, with the highest TFRs at levels above 7 children per woman in such countries as Malawi, Niger, Rwanda, and Uganda. In some countries (such as Cameroon and Angola), fertility has been increasing as sterility rates declined. On the basis of these levels and trends, fertility decline is projected to be slow in the 1990s as well, with replacement fertility in most countries not reached until after 2040. North Africa, on the other hand, has had a substantial decline in the past decade, from 5.6 to 4.6 children per woman, and four out of the seven countries in this region are projected to achieve replacement fertility by 2020.

In Asia, most countries have begun the transition from high to low fertility, with many declines starting before and during the 1970s. In East and Southeast Asia, fertility has already reached a low level of 2.5 children per woman. South Asia, at 4.1 children per woman, has progressed less far in this process, and Southwest Asia has still further to go. However, each subregion of the Asian continent includes countries at different stages of the fertility transition; each subregion has at least one country with a TFR of 6 or greater and one country with replacement level fertility. The projections of when replacement fertility will be reached are determined by the trends in individual countries with the slowest decline; the Asian subregion aggregates will therefore be late in achieving this.

On the American continent, fertility in all countries has dropped to below 6 children per woman, but some countries have gone much further than others. The TFR for Latin America is intermediate at 3.1, and replacement fertility is projected to be reached in every country no later than

2035. In Northern America, fertility is at 2 children per woman, i.e., just below replacement level.

Europe (including the former U.S.S.R. republics) is the only continent where aggregate fertility is currently below replacement, i.e., where women are not having enough children to replace themselves. Recent trends in some countries of Europe show small increases in fertility, and the projections assume that the TFR will recover to replacement level by 2030. Europe is also the continent with the most homogeneous fertility levels: with the exception of four of the former Soviet republics that have TFRs above 3, fertility in the other 41 countries varies in a narrow range between 1.5 and 2.8.

Another measure sometimes used to examine fertility trends is the crude birth rate, a rate that is not adjusted for the age structure of the population. The 1992 crude birth rate for the world as a whole is 25.7 births per thousand population and is projected to decline to 22.2 by the turn of the century, and decline further to 17.8 by 2025. In MDCs, the 1992 crude birth rate is 14.3 while the rate in LDCs is 29.0. Crude birth rates are projected to decrease to 18.6 in LDCs and to 12.2 in MDCs by 2025.

Mortality

Mortality levels in all continents have decreased in the past decade, continuing a long-term trend towards longer life. Life expectancy at birth, a measure constructed from current age-specific mortality rates applied to a cohort born this year, is estimated at 66 years for the world in 1992, with male levels at 64.5 years and female levels at 67.0 years. Life expectancy is 12 years lower in LDCs than in MDCs. Projected mortality trends for individual countries are based on current levels and recent trends, with faster increases in life expectancy projected in countries with lower life expectancies and those with rapid recent increases (see *Data and Methods*). Life expectancy is projected to reach 70 years for the world as a whole in approximately 2010. However, differences between regions are expected to remain important, and even increase in some cases. Sub-Saharan Africa is only projected to reach a life expectancy of 60 years by 2020, and South Asia is not projected to reach 70 years until approximately 2025. On the other hand, more developed regions, are projected to attain life expectancies of 80 years around 2015.

On the African continent, the lowest regional life expectancies are found in East and West Africa where combined (male and female) life expectancy at birth is only 52 and 50 years, respectively. Since the 1970s, life expectancy in East and West Africa has increased by about 6 years. Further increases are expected because of continued progress in socioeconomic development and health interventions; however, in East Africa especially, overall life expectancy will increase only gradually because of increasing mortality from AIDS. In some countries where the HIV/AIDS epidemic has spread widely, such as Uganda, Malawi, and Zambia, projections indicate a reversal of recent gains in life expectancy (see *Special Topic I*). North Africa has considerably better mortality conditions, with combined life expectancy of just over 60.

South Asia has the worst mortality conditions of the Asian subregions, but improvement has been quite rapid since the mid 1970s, with life expectancy increasing from 49 to 59 years currently. Life expectancy in Southwest Asia is near the world's average, while East and Southeast Asia is well-above that at 70 years. East and Southeast Asia contains some of the countries (Japan, Hong Kong) with the highest measured life expectancies in the world.

The American continent contains the Northern America region which has the highest aggregate life expectancy, 76.7. In Latin America and the Caribbean, life expectancy is slightly above the world's average.

xiv INTRODUCTION

The European region has the second highest aggregate life expectancy, 74.4. Every country in this region is above the world's average. Moving from west to east through this region, life expectancies tend to decline, from a high of 78 in Iceland to a low of 66 in Turkmenistan.

Female life expectancy at birth is higher than male life expectancy at birth in all regions in the world, with the exception of the South Asia region, where males and females have the same life expectancy. In some countries in South Asia, such as Nepal and Bhutan, males have higher life expectancies. The largest gaps between males and females are found in some of the former Soviet republics, where females have an advantage of over 10 years (see *Special Topic II*). The variations in the sex difference in life expectancy can often be explained by different life styles, health conditions, and cultural practices. In South Asia, for example, preferential treatment of boys and high maternal mortality rates are important reasons for reduced female life expectancy, whereas alcohol abuse and smoking reduces male life expectancy in parts of Europe.

Other indicators of mortality included in the detailed country projections are the infant mortality rate (IMR), the under-five mortality rate (q_5), life expectancy at age 15, and the crude death rate (CDR). The first three are strongly correlated with life expectancy at birth; the CDR is affected by the age structure of a population and is therefore a much poorer indicator of mortality conditions.

Table 3 summarizes vital rates for geographic regions for the current and two future periods.

Migration

At the regional level, international net migration has a trivial effect on population growth. The most significant flow occurs between Latin America and the Caribbean and Northern America, which amounts to just over one-half million persons per year. Migration often occurs for unpredictable reasons, and is often reversed in a short time period; the projections of future net migration assume a gradual decline to zero from current levels.

Age Structure

The age structure of a population gives information about the size of the school-age population, labor force size, and age-dependency, among others. It is also a very powerful indicator of future population growth potential.

The percentage of the world's population under the age of fifteen is estimated to be 32 percent in 1992, or approximately one in three persons. This proportion is projected to decrease slightly to 31 percent by the turn of the century, and to decline further to 25 percent in 2025 as fertility rates decrease. The trend for the proportion of persons sixty-five years of age or older, on the other hand, is rising in all regions of the world as the result of lower fertility and lower mortality rates at older ages. This proportion is estimated to be 6 percent in 1992, and will increase to 7 percent by the year 2000, and to 10 percent by 2025.

The distribution of persons by age is very different in LDCs and MDCs. In LDCs, 36 percent of the population is under the age of 15, whereas this is only 22 percent in MDCs. By 2025, however, these differences are projected to become smaller as fertility in LDCs is reduced further. At that time, the percentage of the population under the age of 15 is estimated to decline to 27 percent in LDCs and to 18 percent in MDCs.

The proportion of persons aged 65 and over, on the other hand, will be rising, particularly in MDCs. The percentage of this age-group in 1992 in MDCs is estimated to be 12 percent, is

projected to rise to 14 percent by the year 2000, and rise to 20 percent by 2025. In LDCs, the proportion of the population aged 65 and over is only 4 percent in 1992, 5 percent in 2000, and 8 percent in 2025.

The under age 15 and 65 years and over population as a ratio of those in the working ages between 15 and 65 years is called the dependency ratio. This measure indicates how many persons, on average, are dependent per 100 persons of working age. Table 4 shows these three broad age groups for the regions of the world. The dependency ratio is currently highest in Africa, at 92, and lowest in Europe, at 52. Over time, however, dependency in Africa will decrease as fertility declines, whereas it will increase in Europe as the population grows older.

World Bank Regions and Income Groups

The World Bank divides borrower countries into six regions: Sub-Saharan Africa, East Asia and Pacific, South Asia, Europe and Central Asia, Middle East and North Africa, and Latin America and the Caribbean. Within regions, countries are grouped in two to six country departments. In addition, the Bank also assigns each country to one of four income groups. *Box 1* shows the countries grouped by income, *Box 2*, by country department. This section will discuss the population growth, fertility and mortality rates of Bank regions, country departments, and income groups.

The largest region is East Asia and Pacific which currently has 30 percent of the world's population. It is followed by South Asia with 21 percent, Africa with 10 percent, Europe and Central Asia with 9 percent, Latin America and the Caribbean with 8 percent, and Middle East and North Africa with 5 percent. Table 6 shows projections for the six regions and their departments. Figure 5 shows population growth rates for all Bank departments. As the Bank regions resemble geographic regions or subregions, the discussion will focus on Bank departments.

The growth rates of the country departments reflect those of the regions as a whole, but there is some variation. In Sub-Saharan Africa, the rates range from 3.2 percent to 2.8 percent, with the highest rates found in the Eastern African department and the lowest rates found in the Sahelian and Southern African departments.

Another region that has similarly high growth rates is the Middle East and North Africa. The growth rate is higher in the Country Department II, 3.0 percent, which includes the Middle Eastern countries, than the Country Department I, of North African countries, 2.7 percent, where the fertility transition is further along.

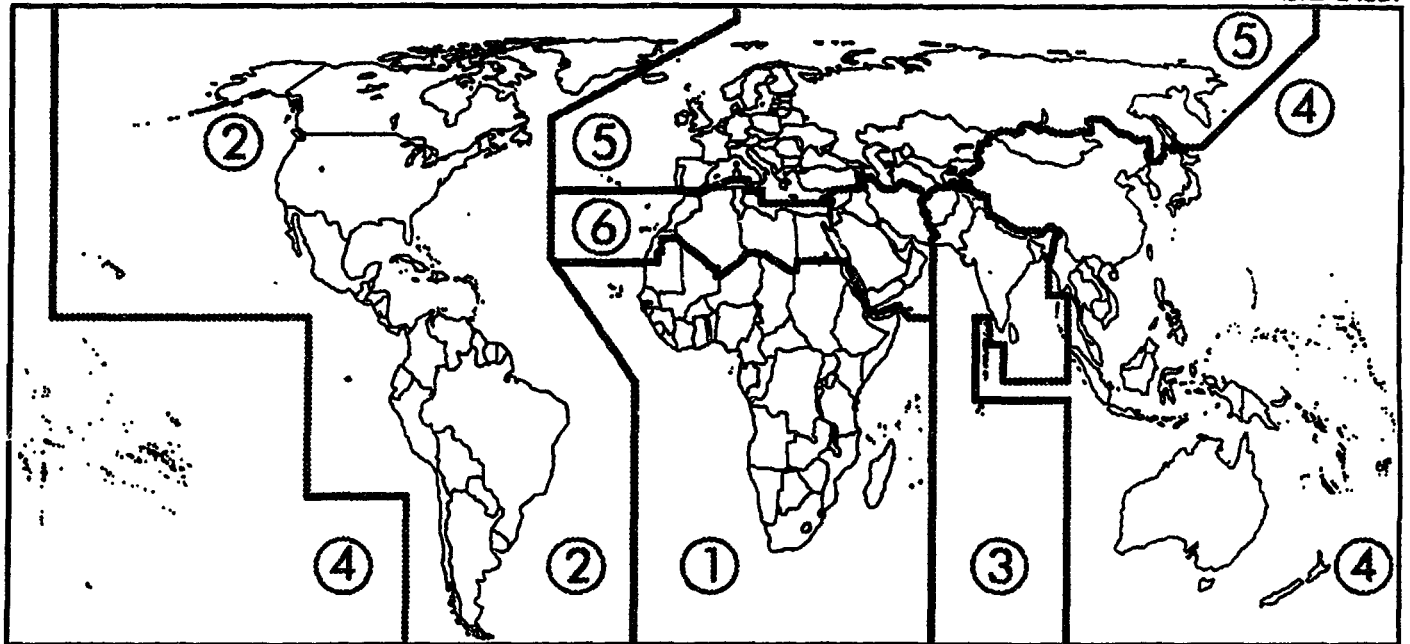

More diversity is found among the Asian country departments. In South Asia, the growth rates for the three departments range from 2.0 percent to 2.6 percent. The growth rates of the three East Asian and Pacific Country Departments are lower and range from 1.9 percent to 1.4 percent.

Latin America and the Caribbean region is similar to the East Asian and Pacific region in that growth rates are moderately high with a range from 2.1 percent to 1.4 percent, with the highest rates found in Country Departments I and II.

The European and Central Asian country departments include Eastern European, Baltic countries, C.I.S. countries, and a few Asian countries and have the lowest growth rates of any of the regions. Country Department I, which includes some Central Asian countries and some Eastern European countries, has a growth rate of 1.3 percent, and the other two departments made up of Eastern European and former Soviet republics have rates of only .4 percent and .8 percent.

¹ As of April 1, 1992

Figure 6 compares TFRs for all country departments. For the Africa region, there is more variation in fertility among the departments than for population growth: TFRs range from 5.6 in the Southern Africa Department (AF6) to 6.9 in the Eastern Africa Department (AF2). In both the Middle East and North Africa and South Asia regions, the fertility rates are medium high -- at 5.5 to 3.7, they are below those of the Africa departments, but above those of all other departments.

The departments in the East Asia and Pacific and Latin America and Caribbean regions have fertility rates that are medium-low: at 3.4 to 2.4 children per woman, they are less than 1.5 to 0.5 children above replacement fertility. Replacement fertility in most countries that constitute these departments is projected to be achieved in the next 10 to 20 years. The Europe and Central Asia departments are very close to replacement fertility, and some countries in this region have dipped below net reproduction rates of 1, which, if sustained, would lead to declining populations in the long run.

Figure 7 compares life expectancies at birth across country departments, and presents an almost reversed ordering of the departments in Figure 6. For the departments of Sub-Saharan Africa, the combined male-female life expectancies are in just above 50 years, the exception being Sahelian Africa (AF5) with a life expectancy of 48 years. In South Asia, the life expectancies are slightly higher, ranging from 52 to 60 years.

In the North Africa and Middle East, East Asia and Pacific, and Latin America and Caribbean departments, the life expectancies are all in the 60-70 years range. Four departments have life expectancies just above 70 years, two of which are in Europe and Central Asia (EC2 and EC3), one in Latin America and the Caribbean (LA4), and one in East Asia and Pacific (EA2).

The income groups, of which there are four, are less distinct demographically than the regional grouping. The low-income group (per capita income in 1990 of \$610 or less), contains 50 countries that are mostly from Sub-Saharan Africa, South Asia, Southeast Asia, with a few countries from Latin America. These countries comprise 58 percent of the world population and have the highest fertility and mortality rates. They include some of the largest countries such as China and India. The 57 lower-middle income countries (per capita income between \$611 and \$2400) have 11 percent of the world population, and include many countries from Latin America, some from all of the other developing areas, as well as some Eastern European countries.

The upper-middle income countries (per capita income between \$2400 and \$7650) have only 10 percent of the world population. Most of the 33 countries that make up this group are from Eastern European and Middle Eastern oil-producing countries. Population growth rates and fertility vary widely within this group, but life expectancies are considerably higher than for the lower-middle and lower income groups. The 42 high income countries have per capita income greater than \$7650, and have 16 percent of the world's population. They are chiefly the more developed countries from North America and Europe and have the lowest fertility and mortality rates, with the exception of Kuwait which has a TFR of 3.4 children per woman.

The difference in population growth between the low- and middle- income groups is not as large as may be expected. The reason for this is the inclusion of China and India, which both have moderate growth rates, in the low income group. As the overall growth rate is an average of country growth rates weighted by population size, China and India depress the low-income growth rate. Without China and India, the low income countries would have the highest growth rate (2.5 percent per year).

Projections for these income groups do not take into account that some countries are likely to move from one income group to another over time.

Some Country Results

Individual country projections provide sharper contrasts than aggregate geographic, Bank region, or income group projections, which, by combining several countries, smooth unique patterns. In this section, results will be discussed for a few large countries, because of their importance in determining the world's demographic situation, and for several smaller countries with striking demographic features.

The most populous country in the world is China with a population of 1.2 billion. Its population growth rate, 1.5 percent in the early 1990s, is low for a low-income country, and is due to the low level of fertility that has been achieved over the last two decades. From 1970 to 1985, the TFR declined from 5.8 to 2.5, where it has stalled in the past few years. At the same time, life expectancy increased from 61 to 70 years, well-above the current average of 59 years for other low-income countries. Because of its sizeable lead in population over the second largest country, and because of the momentum built into the age structure, China is projected to remain the most populous country until 2120.

India, the second most populous country, has an estimated population of 883 million in 1992. Because of its higher TFR, it is growing faster than China -- 2.0 percent per year -- despite higher mortality. The population of India is projected to surpass the 1 billion mark in the year 2000, and to surpass China in total population by 2120.

The United States is, following the breakup of the U.S.S.R., the third most populous country. Its demographic characteristics are those of a typical MDC, with below-replacement fertility, high life expectancy, and an age pyramid that appears increasingly rectangular. The U.S. is atypical in that its growth rate is relatively high as the result of net migration: 25 percent of the United States' annual growth of 0.9 percent is due to immigration. In absolute numbers, the U.S. is by far the largest recipient of immigrants, with an annual immigration surplus of about 600,000 during the early 1990s.

All of the regions have positive growth rates, but a few countries are in fact losing people. These countries are in one of two regions: in Latin America and the Caribbean, where several small island countries (Dominica, Grenada, St. Kitts and Nevis) have recently had negative growth rates, and in Europe (Bulgaria, Hungary, and Ireland). In the case of the Caribbean islands, the cause of population decline is outmigration, whereas in Eastern Europe it results from a combination of below replacement fertility and outmigration. By 2025, a dozen countries in the MDC group are projected to have declining populations, including several large countries (Japan, Germany, and Italy). Even though fertility is assumed to recover to replacement by 2030, the effect of "negative momentum" built into the age structures of these countries is to maintain negative growth rates for several decades.

The highest growth rates are found in countries which have a large number of immigrants relative to their existing populations. The highest annual growth rates in the early 1990s are for Israel (4.8 percent), Jordan (4.8 percent), Oman (4.0 percent) and Saudi Arabia (3.7 percent). However, some other countries attain comparable growth rates through the excess of births over deaths without immigration: Rwanda (3.9 percent), Kenya (3.5 percent) and Swaziland (3.5 percent).

The lowest TFR in the early 1990s is in Italy (1.32 children per woman). Several other Mediterranean countries are similarly low: Spain (1.46), Greece (1.52), and Portugal (1.57). While these countries once lagged the rest of Europe in the fertility transition, they have continued fertility decline to below levels observed in the countries of Northern and Western Europe, some of which (Sweden, Denmark) have had recent slight increases in their TFR.

Six African countries and one country in Asia have TFRs of 7 children or more per woman. The highest is Rwanda (8.3), followed by Yemen (7.7), Malawi (7.6), and Ethiopia (7.5). Countries with such high fertility are expected to eventually follow the pattern of countries such as Kenya and Zimbabwe, which previously had very high fertility and have started the transition from high to low fertility in the 1980s. But some countries with medium-high and high fertility (Mozambique, Tanzania, Niger, among others) are experiencing increases in the TFR as a result of declining prevalence of some sexually transmitted diseases (STDs). STDs cause secondary infertility, which depresses the number of children born to women.

Life expectancy is highest in Japan (79 years, average of male and female life expectancies). This is just more than twice the life expectancy of Guinea-Bissau, which, with 39 years, has the lowest life expectancy of all countries in the world. Age-specific mortality rates, the components from which life expectancy is constructed, show even greater disparities: an infant in Japan has a chance of 5 per 1000 of dying in its first year, whereas this is 30 times higher in Guinea-Bissau. In several Sub-Saharan countries, the probability that a child will not live to age 5 is one in four; in the countries with the best mortality conditions, this is only one in 150 children.

The following set of tables provides additional detail of current estimates and projections of population growth and vital rates. Tables 1 to 5 show demographic indicators for the world, less developed and more developed regions, and geographic regions. Tables 6 to 9 show indicators for the Bank's regions and country departments. Tables 10 to 15 show summary demographic indicators extracted from the main tables to facilitate comparisons among countries. Table 16 shows the populations of small countries that constitute the "other" groupings.

Note: Crude birth rates (CBR) and crude death rates (CDR) are per 1,000 population; total fertility rates (TFR) are per woman 15-49 years of age; life expectancies at birth, e(0), is given in years; and infant mortality rates (IMR) are per 1,000 live births.

Table 4. Population (millions) Age 0-14, 15-64, and 65 and over by Geographic Region

Year and Age group	World	Less developed	More developed	Africa	America	Asia	Europe, former USSR	Oceania
1990								
0-14	1708	1446	261	282	319	1026	173	7
15-64	3231	2427	804	326	448	1922	519	17
65+	329	180	149	19	54	155	98	2
2000								
0-14	1913	1653	260	365	232	1139	170	8
15-64	3830	2989	841	441	533	2299	537	20
65+	425	243	182	25	65	212	119	3
2025								
0-14	2097	1841	256	516	230	1176	166	8
15-64	5405	4546	859	894	692	3243	551	25
65+	844	557	287	56	139	466	177	6

Note: "More developed comprises Europe, the former U.S.S.R., Northern America (the United States and Canada), Australia, New Zealand, and Japan. "Less developed" comprises the rest of the world.

Table 5. Long-run and Stationary Population, Momentum, Doubling Year, and Year when Net Reproduction reached 1 by Geographic Region

	Population (millions)			Stationary population over 1990 population	Stationary population momentum	Year when population doubles	Year when NRR=1	
	1990	2050	2100					
World	5268	10055	11652	12186	2.3	1.4	2059	2060
Less Developed (a)	4053	8623	10200	10715	2.6	1.5	2040	2060
More Developed (a)	1214	1433	1452	1471	1.2	1.1	(b)	2030
Africa	627	2079	2784	3028	4.8	1.5	2017	2055
East Africa	272	1006	1399	1498	5.5	1.5	2015	2055
West Africa	215	730	978	1105	5.1	1.5	2016	2055
North Africa	140	343	408	425	3.0	1.6	2029	2050
America	721	1201	1285	1311	1.8	1.4	(b)	2035
Latin America and Carib.	441	839	916	938	2.1	1.5	2067	2035
Northern America	280	362	369	373	1.3	1.1	(b)	2030
Asia	3103	5811	6596	6846	2.2	1.4	2068	2060
East and Southeast Asia	1788	2840	3013	3086	1.7	1.4	(b)	2040
South Asia	1182	2570	3076	3232	2.7	1.5	2040	2060
Southwest Asia	133	401	507	528	4.0	1.6	2019	2055
Europe and former U.S.S.R.	790	922	941	955	1.2	1.1	(b)	2030
Oceania	27	43	45	46	1.7	1.3	(b)	2035

a. "More developed comprises Europe, the former U.S.S.R., Northern America (the United States and Canada), Australia, New Zealand, and Japan. "Less developed" comprises the rest of the world.

b. Population will not double with projected rates.

Table 6. *Population and Percentage Distribution by World Bank Region, Country Department, and Income Group, 1985-2100*

SPECIAL TOPIC I: PROJECTING AIDS MORTALITY

This section describes the methodology used to incorporate AIDS mortality in the projections and compares resulting demographic indicators with those constructed if AIDS is not incorporated, as in previous editions of the World Bank's projections. The methodology makes use of an epidemiological model developed at the World Bank that simulates the spread of HIV, and the demographic model used to do the population projections (Bulatao and Bos, 1992). Simulations of the effect of current HIV prevalence on projected future mortality are used to derive equations that can be applied to populations with measurable levels of HIV infection with a minimum requirement for data.

Epidemiological model

The epidemiological model, developed by Bulatao (1991) consists of a numerical simulation of three processes: the spread of HIV, the development of AIDS among those infected with HIV, and the progression from AIDS to death. The three processes are modeled separately for adults (those aged 15 years and over) and children. The model allows HIV to spread sexually between partners, through blood transfusions, infected needles, and perinatally between mother and child.

Sexual transmission

In handling the sexual transmission of HIV, the model first divides all adults in the population into four sexual orientation groups: females (assumed to be all heterosexual), heterosexual males, homosexual males, and bisexual males. Females are assumed to choose partners from among heterosexual and bisexual males; heterosexual males from among females; homosexual males from among themselves and bisexual males; and bisexual males from females, homosexual males, and among themselves. Within each group, up to ten subgroups varying by sexual behavior can be defined. Those who have developed AIDS are assumed not to be sexually active, and therefore are effectively in a no-sex subgroup.

Given some initial assumption about the proportion infected with HIV in a particular year, the number sexually infected in each subsequent year is calculated subgroup by subgroup. In its basic form, the calculation of the number of HIV seroconversions (O) in one year (t) in a given subgroup (s) of one sexual orientation group (r) is given by

$$O_{rs,t} = M_{rs,t-1} P_{t-1} \{1 - (1 - O_I) (1 - O_T) (1 - R_{rs,t-1} [1 - (1 - T_r)^S])^{F_{rs}}\} \quad (1)$$

where M is the number of HIV seronegatives in the subgroup, P is the likelihood of adult survival from mortality unrelated to HIV, R is the proportion of potential sexual contacts, or agents, who are infective, T is the likelihood of transmission to group r through sexual contact, S is an average number for sex acts per partner, and F is the annual number of new partners. (Different values of F and S are the main factors distinguishing sexual orientation subgroups.) O_I and O_T will be explained below.

The proportion of agents (R) infective to subgroup s is the weighted proportion across all other subgroups with which subgroup s has sexual contact who are asymptomatic but HIV-seropositive (A). The weights used are the frequencies (F) with which these other subgroups take new sexual partners. The asymptomatic seropositives (A) in a given subgroup are calculated by summing up all those infected in previous years and subtracting those expected to progress to AIDS or to die from other causes.

MI SPECIAL TOPIC I: PROJECTING AIDS MORTALITY

No restrictions are placed on the way sexual orientation groups are divided into subgroups or on the values of F and S specified for each subgroup. Inconsistent parameters, requiring for example that males have many more sexual partners in the aggregate than the available females, can be used as input. The model adjusts the input figures if necessary, essentially taking averages or adjusting figures proportionally, in order to force them into consistency. These adjustments are made for each year of the simulation, as the number and distribution of the sexually active changes.

Nonsexual transmission

Infection with HIV through needles and blood accounts for the terms O_1 and O_T in equation (1). The adult population is divided into crosscutting subgroups for number of annual transfusions and number of annual injections, with the bulk of adults typically assumed to be in zero-frequency subgroups. The probability of infection (O_1 or O_T) in each subgroup is then a function of the proportion of "agents" (needles or blood) infected, the likelihood of transmission through a single exposure to an infected agent, and the frequency of such exposure, through injections or transfusions, for the particular subgroup. The formula is similar to (1), leaving out a few irrelevant terms.

The proportion of needles infected is equal to the proportion of adults infected, weighted by the frequency with which each receives an injection. The proportion of blood infected is equal to the proportion of adults infected, optionally weighted by propensity to donate blood, which can be specified for each sexual orientation subgroup. Both these proportions can be modified, the first by a specified proportion of needles sterilized and the second by a specified proportion of blood screened.

For perinatal, or vertical, transmission, the number of infected newborns is the product of the number of women of reproductive age, the proportion of women infected (including, in this case, those who have progressed to AIDS), the general fertility rate, and an optional adjustment factor that can be used if it is assumed that those infected have either higher or lower fertility than others. The model does not allow overall fertility to be affected by use of this adjustment factor, implying in effect that fertility among those not infected either rises or falls to counterbalance the adjustment. Nor does the model make allowance for children being infected in any other fashion, nor for their transmitting the virus to anyone else.

Progression from HIV to AIDS

The number that progress to AIDS is determined by applying separate schedules for adults and children that depend on year since initial infection, after excluding mortality from other causes. The model therefore keeps track of cohorts of HIV seropositives distinguished by infection date, so that appropriate progression rates can be applied. A logistic function of the form

$$H = k / [2 + \exp(a + bt)] \quad (2)$$

is presently applied in generating the schedule, but alternative functions can in principle be incorporated. The progression from infection to frank AIDS for both adults and children can be modeled with the same functional form, with the parameters set to allow substantially faster progression for children.

Progression from HIV to AIDS

Progression from AIDS to death is handled in a similar manner as progression to frank AIDS, using a logistic pattern.

Model complications

Several additional features of the model mainly affect the transmission process and allow tests of the effects of various unknown parameters. These features, listed below, can be ignored in a routine run of the model.

(i) *Random movement between sexual orientation subgroups.* Membership in the four main sexual orientation groups is assumed to be fixed. Within these groups, subgroup proportions are initially specified by the user, and these proportions are applied to the initial population and to all those entering adulthood each year. In one scenario, each individual stays in the same subgroup all his or her life. In an alternative scenario, some proportion of individuals moves between subgroups each year. The model allows specification of a fixed proportion of individuals who move randomly among subgroups, with the likelihood that they enter a given subgroup being proportional to the distribution across subgroups. This is accomplished computationally by redistributing the specified proportion of individuals each year before calculating seroconversions.

(ii) *Infective phases.* Different probabilities of transmission can be entered for contact between susceptibles and particular infective agents--men, women, needles, blood, mothers. In addition, human agents can be allowed to vary in infectivity over time. The period between infection and development of AIDS can be divided into up to six segments of varying length, for each of which a specific probability of transmission can be specified. (Since the entire period varies in length across individuals, the segments are proportional rather than of absolute length.) Computationally, this affects equation (1), in which the term

$$R_{t,t-1} [1 - (1 - T_t)^{S_t}] \quad (3)$$

is actually calculated as the summation of similar terms for each of the infective phases.

(iii) *Cofactors.* The model allows condom use, genital ulcers, and one user-specified cofactor to affect infection by acting as a multiplier of transmission rates. In the case of condoms, for instance, transmission rates may be multiplied by .1 or .2 or some other value for those using condoms. An appropriate multiplier and the proportion in each sexual orientation subgroup to whom the cofactor applies must be specified. From period to period, those to whom the cofactor applies may stay essentially the same or may change randomly.

(iv) *Anal sex.* On the assumption that anal sex carries different risks from other forms of sex, the user is allowed to specify what this greater risk is and what proportion of sex acts involve anal intercourse for each sexual orientation subgroup.

(v) *Genetic variability.* The adult population can be divided into two or three groups of arbitrary size with varying susceptibilities to infection. These groups crosscut the sexual orientation groups. A multiplier for the transmission rates and a relative size must be specified for each group. Computationally, this creates additional compartments in the model but does not change the basic formulae.

(vi) *Changes in parameters.* The model allows changes over time in several parameters. This is accomplished by selecting a date for changes to start and a percentage by which the parameter will rise or fall annually. Changes are allowed in all these parameters: transmission probabilities, sexual behavior, proportion of blood screened, proportion of needles sterilized, proportion using condom, and proportion with genital ulcers. This option allows testing the effects of various interventions, such as those directed towards behavioral change, STD programs, and other medical interventions,

on the spread of HIV (See Bulatao and Bos, 1989b, for an example).

(vii) *Attraction matrix.* The basic model assumes proportionate mixing among the relevant subgroups, modified by the frequency with which each subgroup chooses partners. A further modification can be made if one wishes to assume that contact between particular subgroups is more likely than contact between others. An "attraction matrix" is defined providing weights for the likelihood of contact between every pair of subgroups. These weights are used in calculating the proportion of agents (R) that are infective to a given subgroup. A weight of 2, for instance, implies in effect that members of each of the two subgroups, in looking over possible partners, behave as if there were twice as many members of the other subgroup as there actually are. As with other sexual behavior parameters, the attraction matrix can be input in an unbalanced form, and will be forced into balance, which is accomplished through an iterative process.

(viii) *Urban-rural differences.* By defining additional subgroups and using an attraction matrix, it is possible to run a simulation with separate urban and rural sectors. Each sexual orientation subgroup must be divided into two groups, one rural and one urban. The attraction matrix can then be used to increase likelihood of contact within sectors and reduce contact across sectors. In addition, if the proportion of the population in the urban sector in each year is defined, the model shifts sufficient numbers of people between the parallel subgroups in each sector to meet these figures.

Demographic Model

The demographic model that is linked to the epidemiological model is a variant of the standard cohort-component model used to produce population projections in the absence of AIDS (See *Data and Methods* and Hill, 1990).

The epidemiological model keeps track of age at death due to AIDS among children. Deaths due to AIDS among adults are distributed across five-year age groups according to an age-sex distribution provided by the user. These are translated into probabilities of dying, which, because they already exclude mortality from other causes, can be simply added to the life table values that are among the vital rates that drive the demographic model. Some aggregation is necessary because the epidemiological model generates annual estimates, while the demographic model generates quinquennial estimates.

Simulations

A major obstacle to applying the model to Sub-Saharan countries is the unavailability of data required in the model. This concerns especially the behavioral components affecting the spread of HIV. Other required data, such as transmission rates of the virus, the progression to AIDS and death, and the effects of ulcers and condom use, are to some extent transferable from other settings. To circumvent the data problem, and to reduce the amount of input that would be required to apply the model for each Sub-Saharan country with discernable levels of HIV infection, the relationships between current HIV prevalence and future mortality from AIDS were extracted from a set of simulations produced by running the model with standard parameters for a hypothetical population.

Modelling approach

The approach followed here involves running the above models many times with varying

values of sexual behavior variables to match arbitrarily fixed levels of HIV prevalence in 1990: low prevalence (1 percent of the adult population), intermediate (3 percent) and high (6 percent). In these simulations, sexual behavior parameters are manipulated to achieve the specified HIV prevalence, whereas other variables are set at one of three levels. These variables, selected because of their significance in the spread of the virus established in previous applications of the model (See, e.g. Bulatao, 1991) and because of known variations in conditions in Sub-Saharan countries, are: condom use, the prevalence of genital ulcers, and the intensity of blood screening. In addition, three different starting years (1970, 1975, and 1980) for the epidemic were used. The combination of every level of these variables, shown in table S1 below, results in a total of 243 simulations, which were run from the start of the epidemic until 2025.

Other parameters of the model, such as fertility levels and trends, mortality from other causes, age structure, transmission rates, progression of children and adults from HIV to AIDS and death were selected on the basis of available information from surveys and surveillance systems in Sub-Sahara African countries (U.S. Bureau of the Census, 1991). Especially useful in establishing parameter values were also "standard parameters" developed for HIV modeling exercises at the United Nations and at Family Health International (United Nations/World Health Organization, 1991; Family Health International, 1991). Table S2 shows a summary of the assumed parameter values used in the simulations.

Further assumptions were necessary regarding the course of the epidemic in the future. While intensive efforts to develop a vaccine are reported to be making some progress, at this time it does not appear likely that an effective vaccine will be available in the next few years. Arbitrarily, it is assumed that an effective medical intervention will become available in 2005, and that transmission of the virus resulting in new HIV infections will be cut in half each year thereafter.

It is also assumed that there is no interaction between HIV prevalence and fertility, or between AIDS mortality and mortality from other causes (other than that an individual who succumbs to AIDS cannot die of another cause). The evidence of individuals adjusting their fertility behavior based on the prevalence of HIV is very limited, and hypotheses for either an increase and a decrease in overall fertility have been proposed (World Bank, 1990; Ryder et al., 1991).

Simulation results

The simulation output gives projections of HIV prevalence from 1990 to 2025 in the presence of varying levels of the cofactors, and of several resulting mortality indicators. The analysis of the simulation results consists of two steps. First, it is examined how well future HIV prevalence can be predicted from 1990 prevalence in these simulated scenarios. Second, the relationship between HIV prevalence and mortality indicators is examined. As AIDS mortality in Sub-Sahara Africa affects both adults and young children, both the effects of HIV level on future life expectancy at age 10 and on future mortality of children under five are analyzed.

Regression analysis is used to establish the relationship between 1990 prevalence and future prevalence, separately for males and females. In order to linearize trends over time in these data, logarithmic transformation of HIV prevalence are used. Table S3 shows the regression coefficients to predict future HIV prevalence from just three variables: 1990 HIV prevalence, 1990 HIV prevalence squared, and the year that the epidemic started. The model fits the data very well, especially early in the projection period, and the R^2 never drops below 0.85.

Table S1. HIV transmission factors and their values used in simulations

Variable	Values
Starting year of spread of HIV	1970, 1975, and 1980
Condom use	low (1%), medium (2%), and high (3%); increased gradually after 1990
Genital ulcers prevalence	medium: 0.001-7.5%, depending on risk subgroup; decreased gradually after 1990
	high: double the medium value
	low: half the medium value
Blood screening	low (5%), medium (10%), high (20%); increased gradually after 1990
Sexual behavior	Number of new sexual partners per year varied to achieve 1990 HIV prevalence of 1%, 3%, and 6%

Regression analysis is also used to establish the relationships between the level of adult HIV infection and mortality indicators in the future. The effects for adult males and adult females are estimated separately, and the effects on children's mortality is estimated from female infection rates. Table S4 shows regression equations, with life expectancy at age 10 the dependent variable for the equations including HIV prevalence, HIV prevalence squared, and the starting year of the epidemic as independent variables for adults. For children, under-five mortality is the dependent variable, and HIV prevalence for women the only independent variable. Given that these regressions use data generated with simulations, eliminating the effects of extraneous factors, it is not surprising that the R^2 values are so high.

As stated above, these results apply to a hypothetical population with overall mortality levels as in Eastern Africa. The equations would underestimate the impact of AIDS in countries with lower mortality from other causes and overestimate the impact where mortality is higher. Further analysis showed that for the projection purposes, the application of an adjustment factor equal to the squared ratio of a given life expectancy and the hypothetical population's life expectancy would produce consistent results. This adjustment factor is applied to the number of years lost due to AIDS.

Application to Sub-Saharan African countries*Data*

Estimates of HIV prevalence in 1990 for all Sub-Saharan African countries were made by Chin (1991) at the World Health Organization, and are summarized in Figure S1. These estimates were for males and females combined; based on the simulations, it is assumed that female HIV prevalence is 1.2 times male prevalence. HIV-1 and HIV-2 have been combined in one overall HIV estimate. Starting years of the epidemic were derived from the U.S. Bureau of the Census' AIDS data base (1990).

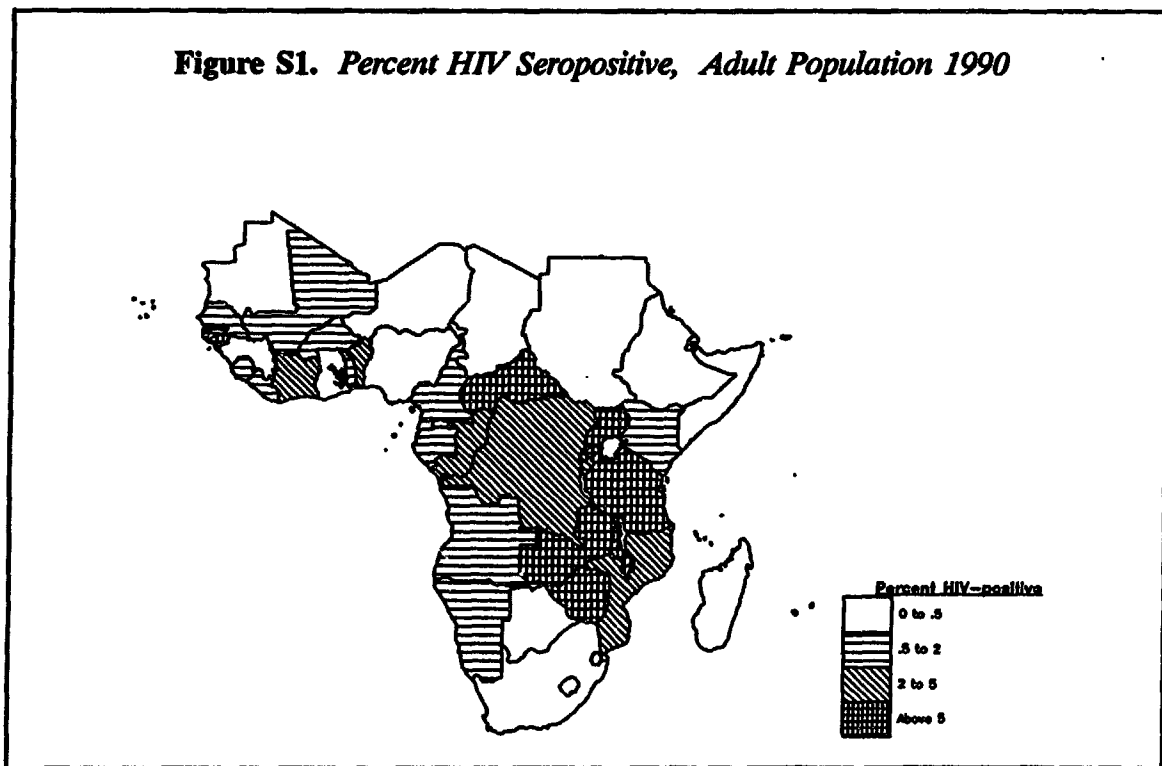

Table S2. Parameter values used in simulations

Demographic variables	
Fertility	Total fertility rate declines from 6.5 during 1985-1995 to 6.2 in 1995-2000, and by 0.6 units thereafter. Age specific fertility pattern like Eastern Africa aggregate.
Fertility adjustments	No fertility adjustments because of HIV/AIDS are made.
Mortality (non-AIDS)	Mortality from causes other than AIDS follows Eastern Africa aggregate pattern. Life expectancy gradually increases from 55.6 during 1985-1990 to 68.7 during 2020-2025. Infant mortality declines during the same period from 93 to 34.
Mortality adjustments	No interaction between AIDS mortality and mortality from other causes is assumed.
Age structure	The 1985 age-sex distribution equals the Eastern Africa aggregate, with 46% below age 15 and 51% between ages 15 and 65.
Transmission rates	
Heterosexual contacts	Male to female transmission averages 0.002; female to male, 0.001. Transmission rates vary by duration since infection of the infected partner.
Homosexual contacts	It is assumed that homosexual contacts are insignificant and can be ignored.
Blood transfusions	Receiving a blood transfusion with infected blood is assumed to have a transmission rate of almost 0.999.
Injections	Receiving an injection with an infected needle is assumed to have a transmission rate of 0.005.
Perinatal	Perinatal (or vertical) transmission from is assumed to average 0.3.
Cofactors: ulcers	A multiplicative factor of 40 is applied to transmission rates when a susceptible partner has genital ulcers.
Cofactors: condoms	A multiplicative factor of 0.2 is applied to transmission rates when a condom is used.
Anal sex effect	No adjustment of transmission rates is assumed for either receptive or insertive anal sex.
Risk group membership and characteristics	
Risk group membership: males	30% monogamous; 40% low sexual activity; 20% medium sexual activity; 10% high sexual activity
Risk group membership: females	50% monogamous; 30% low sexual activity; 15% percent medium sexual activity; 5% prostitutes
New contact frequency: males	Monogamous: 0.05 new contacts per year; low: 2; medium: 15; high: 50. Contact frequencies adjusted in simulations with different HIV prevalence levels

SPECIAL TOPIC I: PROJECTING AIDS MORTALITY lxiii

New contact frequency: females	Monogamous: 0.05 new contacts per year; low: 2; medium: 5; prostitutes: 200. Contact frequencies adjusted in simulations with different HIV prevalence levels
Blood transfusions	90% percent never receives a blood transfusion; 8% has 0.1 frequency of receiving blood; 1% has 1 exposure; 1% has 5 exposures
Injections	70% percent receives 0.1 injections; 10% has 1 frequency of receiving an injection; 10% has 3 exposures; 10% has 10 exposures
Genital ulcers prevalence	Medium value for monogamous males and females: 0.0001; low sexual activity: 0.0005; medium sexual activity: 0.02; high sexual activity, males: 0.1; female prostitutes: 0.2
Disease progression	
Adults: HIV to AIDS	Progression follows a logistic curves, with parameters $a=2.77$, $b=0.3$, $k=0.9$. This has a median of 10 years, with 90 percent of those infected ultimately developing AIDS
Children: HIV to AIDS	Progression follows a logistic curve, with parameters $a=3$, $b=3$, $k=0.98$
Adults: AIDS to death	Progression follows a logistic curve, with parameters $a=1.5$, $b=1.5$, $k=0.999$
Children: AIDS to death	Progression follows a logistic curve, with parameters $a=4$, $b=4$, $k=0.999$
Other parameters	
Random proportion for cofactor group	It is assumed that an individual's status on ulcer and condom cofactors is 10% random, in comparison with their status in the previous year.
Random subgroup proportion	It is assumed that subgroup membership is 10% random, in comparison with subgroup membership in the previous year
Condom-genital ulcers association	It is assumed that there is a -0.75 correlation between an individual having genital ulcers and using a condom.
Genetic variability	No variability in genetic susceptibility to infection is assumed.
Blood donation propensity	Is assumed not to vary by risk group.
Attraction matrix	Proportionate mixing is assumed

Procedures

The regression equations estimated above were incorporated into the World Bank's standard procedures for projecting mortality (Bulatao and Bos, 1989a). The procedures were modified as follows: first, the level and pattern of mortality is projected under no-AIDS circumstances, and appropriate Coale-Demeny model life tables are selected. Using adult HIV prevalence in 1990 and an estimated starting year of the epidemic, HIV prevalence in future years is calculated with the regressions in Table S3. Next, years of life expectancy lost due to AIDS mortality of children and adults is calculated with the regressions in Table S4. Finally, the number of years lost, expressed as Coale-Demeny model life table levels, is subtracted from the projected no-AIDS trends until 2020-25, after which mortality recovers gradually to the projected level in 2050 under a no-AIDS situation.

Results

The estimated impact of AIDS on demographic indicators will be presented for all Sub-Saharan African countries combined and the impact of AIDS on total population will be given for individual countries. Figure S2 shows projected population and Figure S3 the population growth rate for 1985-2020, comparing the revised World Bank projections that incorporate AIDS mortality and previous projections without AIDS mortality, which are otherwise identical. The difference in the number of people is hardly discernable before the end of this decade, but keeps growing and reaches 49 million in 2020. The difference in the growth rate is at most 0.15 percent. The differences are not only due to AIDS mortality, but also to fewer births resulting from fewer women of reproductive age. The contrast between the AIDS and no-AIDS scenarios is much more pronounced for life expectancy (Figure S4), which immediately shows a lower rate of increase and a divergence of as much as 3.5 years. Figure S5 shows the number of deaths due to AIDS, added to deaths from other causes. At its peak, AIDS adds 1.3 million deaths annually to the 9.5 million deaths from other causes. Long-term implications of the HIV/AIDS epidemic are shown in Figures S6 and S7. Life expectancy is assumed to recover fully to the no-AIDS levels by 2050; total population, will, *ceteris paribus*, never catch-up with the population projected in the no-AIDS scenario. Such long-term projections are, of course, much more dependent on the assumptions made regarding the future course of the epidemic and the effectiveness of interventions than are projections for the short-term.

Table S5 shows the percentage difference in projected population in AIDS and no-AIDS scenarios for all countries of Sub-Saharan Africa for 2000, 2020, and 2050. The mean difference in 2000 is 0.8 percent, in 2020, 3.2 percent, and in 2050, 5.2 percent.

Conclusions

While the impact of AIDS on population *could* certainly be more severe than shown here, especially if various conditions conducive to the spread of HIV would prevail, the results indicate that even in severely affected countries population growth is likely to continue at high levels. Short-term effects were shown to reverse gains made in life expectancy over the past decades and to increase the crude death rate, but not to an extent that population growth is reduced by more than 0.5 percent in the countries with the highest infection levels.

It must be stressed that many parameter estimates for model variables are based partly on conjecture rather than on empirical data. While the model has been used to effectively simulate the spread of the epidemic from its start in the early 1970s to the present (See, e.g. World Bank, forthcoming), there is no guarantee that the same parameters will hold in the future. Further uncertainty is introduced by the unknowable future course of the epidemic, which in this analysis is assumed to be drastically reduced after 2005. As with most projections, the short-term effects are accompanied by much less uncertainty than the longer range projections. In the case of HIV/AIDS, with its long incubation period, mortality in the next several years is mostly the result from infections that occurred in the past 10 or so years. If an estimate of HIV prevalence is available, projections of mortality from AIDS should be quite reliable. The more difficult part is clearly projecting the spread of HIV, as this is subject to behavior that does not lend itself to easy inquiry.

SPECIAL TOPIC II: DEMOGRAPHIC TRENDS IN THE REPUBLICS OF THE FORMER U.S.S.R.

Since the previous edition of *World Population Projections* was issued, the U.S.S.R. has dissolved and become fifteen separate countries for which individual projections are provided in this volume for the first time. The demographic situation in these countries is quite diverse as a result of past differences in vital rates and migration, and their demographic prospects are consequently very different as well. This section focusses on the recent demographic history of and prospects for the former Soviet Republics, which, because they constituted one country, has not been presented before.

Population growth and distribution

Of the fifteen countries, the largest is the Russian Federation with over half of the population of the former Soviet Union, as is shown in Figure S1. The next largest are, in order, the Ukraine, Uzbekistan, Kazakhstan, and Belarus. The other ten countries contain only 12 percent of the total population of the former Soviet Union. Thus, while the Russian Federation is by far the largest country of Europe, most of the former Soviet republics resemble many other countries in the region in the size of the total population. Land areas of the countries vary even more widely than population totals; as a result, population densities are very uneven, ranging from 129 persons per square kilometer in Moldova, to 8.7 persons per square kilometer in the Russian Federation, which includes the vast and sparsely populated Siberian regions.

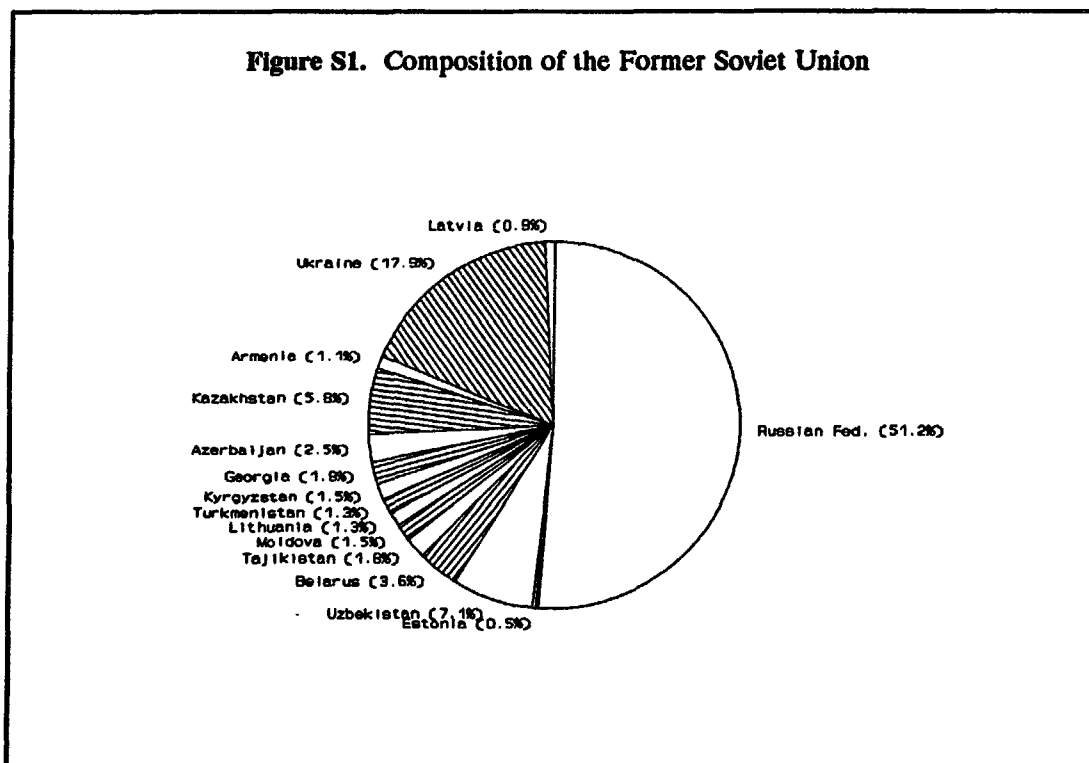

Figure S2. Population Growth Rates, 1990

Figure S2 compares annual population growth rates for the period 1990-94. Five countries have growth rates over 1 percent, whereas most of the other countries' growth rates hover around 0.5 percent per year. These rates show a clear geographic pattern, with the Central Asian countries mostly having high growth rates. Tajikistan, Uzbekistan, Turkmenistan, Kyrgyzstan, and Azerbaijan, which together have only 14 percent of the population of the former Soviet Union account for 40 percent of the increase in population in all fifteen countries. One consequence of the differences in growth rates is that the composition of the region will gradually change. For example, the share of the Russian Federation of the region's total will drop from just over 51 percent now to 47 percent by 2025.

Figure S3. TFR in Former Soviet-Union Republics

Fertility

The main reason for the differences in population growth rates is the variation in fertility. Figure S3 compares the TFR in 1992 for all 15 countries. Figures S4 and S5 show trends in the TFR from 1960 to 1990. Two sets of countries can clearly be distinguished: those with high and medium-high fertility (Figure S5) and those with fertility near replacement (Figure S4). For most of the high and medium high-fertility countries, trends since 1980 are generally downwards, although at a slow rate. The low fertility countries have been mostly stable at low levels since the 1960s. An exception is Armenia, which joined the low fertility countries only in the mid-1970s.

Figure S4. Trends in TFR, low fertility countries

Figure S5. Trends in TFR: high fertility countries

Figure S6. Difference in e(0) from USSR average

Figure S7. Trends in e(0)

Mortality

Differences in life expectancy are not as pronounced as those for fertility and population growth. Figure S6 shows estimated 1992 life expectancy (male and female) from the Soviet Union average for each country. Belarus is highest, with a life expectancy that is two years higher, and Turkmenistan stands out with a life expectancy five years below the Soviet Union average. Recent trends in life expectancy for males are shown in Figures S7 and S8. As with fertility, clear geographic patterns are noticeable, with lower life expectancies for the Central Asian countries. Life expectancy increased in most countries by one to two years during the 1980s although there was a sizable one-time drop in Armenia's level attributable to the 1988 earthquake. One of the more remarkable demographic features of some of the former Soviet republics is the large differences between male and female life expectancy (Figures S9 and S10), reaching a high of 10.5 years in Russia -- the highest observed difference in the world. These disparities between male and female life expectancy are probably due to greater alcohol and cigarette consumption by men (Dutton 1981).

Although infant mortality increased somewhat during the 1970's (possibly due to improved reporting), it has been decreasing over the last decade for all of the countries. However, considerable diversity still exists in the rates which are higher in the Central Asian countries and lower in most of the other countries. The infant mortality rates range from 54 in Turkmenistan to 15 in the Ukraine and Belarus.

Figure S9. Differences between male and female $e(0)$

Figure S10. Differences between male and female $e(0)$

Migration

Internal migration played an important role in the spatial distribution of the population of the Soviet Union. Government policies aimed at balancing requirements for labor and population; however, they were only partly successful. In the 1960s, efforts to settle outlying areas in Siberia were largely ineffective, while the Central Asian republics, which already had a labor surplus, continued to attract more migrants. In the 1970s, however, there was significant change in the direction of interregional migration trends (Zayanchkovskaya, 1991). Western Siberia started to experience a large influx of population, and the Central Asian republics began to have large migration deficits. These trends continued in the 1980s. The North-Western and Central regions (Moscow and St. Petersburg and their districts) attracted large number of migrants throughout the period.

Several factors are conducive for intensified migration in the 1990s. The change to a market economy, which is likely to result in differentials in wages and employment opportunities, will create labor markets with strong incentives to move to the economically more developed countries. Past migration trends have led to considerable ethnic diversity in some of the countries, whereas others have remained more homogeneous. Over 25 million Russians live outside the country in other former Soviet Union republics, while Armenia's population is 93 percent ethnic Armenians (Scherbov and Andreev, 1992). The consequences of ethnic dispersion for future migration flows are hard to anticipate; at its worse, it could

result in substantial refugee flows when ethnic frictions erupt, as in the Armenia-Azerbaijani conflict. Full freedom of movement was restricted in the former Soviet Union; to what extent new migration policies will limit the movement of people among the new countries remains to be seen. In addition to economic, ethnic, and political factors, natural and environmental disasters may increase future migration. The Chernobyl nuclear accident has caused large outmigration in the areas of the Ukraine, Belarus, and Russia most affected by contamination.

DATA AND METHODS

The data used in each projection include base-year (mid-1985) total population estimates and age structures by sex, and base-period (1985-90) mortality, fertility and migration rates. The data, their sources and how they are derived when insufficient information is available, will be described in this section. The sources of each country's base data can be found in Table A3.

D.

Population and age-sex structure

Estimates of the mid-1985 populations are obtained from the most recent reliable sources. When possible, these estimates are obtained from recent census totals projected to mid-1985, after adjustments have been made for under- or over-reporting. Provisional census figures that have not been evaluated are not used. A major source of adjusted census figures is the U.N. Population Division. Other sources include the U.S. Bureau of the Census, Eurostat and, for the former Soviet countries, the U.S.S.R. census publications. When no recent census figures are available, official estimates are often adopted, frequently as reported by the U.N. Statistical Office in *Population and Vital Statistics Report*. In addition, base-year population estimates may be obtained through projections of past census results with fertility, mortality, and migration rates from vital registration or surveys.

Age-sex structures are distributions of the population by age and sex. As is the case for total population, the U.N. Population Division provides many of the age-sex structures, which generally are census age structures adjusted for age-misreporting or estimations using stable population analysis when necessary. Other sources include World Bank and official estimates from recent censuses and projections from earlier censuses.

Estimates based on a more recent census generally provide more reliable information than estimates constructed through projections from earlier censuses. However, some European countries have not had a census in decades, but maintain very accurate demographic intelligence through population- and vital registers. Most other countries lack complete registration systems and rely on censuses, usually taken ten years apart, often supplemented with intercensal surveys. Figure A1 summarizes the currentness of census counts.

Mortality data

Base-period mortality levels in the projections are indicated by life-expectancies at birth by sex and infant mortality rates for both sexes combined. Life expectancies for the quinquennia 1975-80, 1980-85 and 1985-90 were obtained from a variety of sources, with the U.N. Population Division being the most frequent one. Others are based on estimates published in *Population and Vital Statistics Report*, DHS reports, statistical yearbooks, census publications, World Bank reports, Eurostat (1991), Monnier and Guibert-Lantoine (1991) and the U.S. Bureau of the Census. In cases where data are not available for the desired quinquennium, or give indices other than life expectancies, some estimation and projection is then necessary to obtain the right index. Further detail about the construction of current mortality estimates may be found in Bos et al. (1992).

Infant mortality rates, like life expectancies, are taken from a variety of sources. A frequently used source is the U.N. *1990 World Population Prospects*. Other sources include surveys,

Figure A1 Distribution of countries by year of latest census

censuses, official estimates, USBOC, Eurostat and World Bank estimates. The mortality risk for children under age 5 for the current period is derived from a model described below. Earlier estimates are often taken from the U.N. publication *Mortality of Children Under Age 5*.

Fertility data

Total fertility rates are derived from similar sources as mortality rates, including the U.N.'s *World Population Prospects 1990*, surveys, censuses, and the U.S. Bureau of the Census. The DHS survey are a particularly useful source of data. Other sources include official estimates, Bank estimates, and Eurostat. Because fertility rates are not always available for the specified period or are in terms of another parameter such as the crude birth rate, total fertility rates are sometimes obtained by projections of earlier estimates or approximated using available data on age-sex structure and age-specific fertility.

Migration Data

Estimates of net international migration are obtained from a variety of sources including statistics from national immigration agencies, statistical organizations, official sources, interagency task forces and research institutions. Arnold (1989) compiled all these data. Updates of this information have been made as more data has become available.

In developing these estimates, migrants are considered persons who have resided in countries different from their previous residence for at least a year or who are believed likely to remain permanently in receiving countries. Persons are not counted as migrants when they are refugees living in officially designated camps. Only net estimates are made by quinquennium; immigration and emigration are not estimated separately, and single-year figures were not assessed.

Projection methodology

Population projections were run using the cohort-component method on microcomputers with the software package, PROJ3L. (A similar program, PROJ3S, is described in Hill (1990), the only difference being that this program allows for 75-year projections rather than long-term projections shown here. The assumptions about future trends in vital rates will be discussed in this section.

Projecting Mortality

The procedures used to project mortality were developed from analysis of trends in life expectancy and infant mortality in available national data. (See Bulatao et al., 1989). These projections utilize extended life tables (see Coale and Guo, 1989) with maximum male and female life expectancy assumed to be 83.3 and 90 years, respectively. These maxima were revised upward in 1991 because previously used maxima are now barely above the currently estimated levels for the lowest mortality countries. Life expectancy in Japan, for instance, is estimated at 75.6 for males and 81.4 for females - only slightly below the previously used maxima. Research into the consequences of controlling major risk factors has found that theoretically much higher life expectancies are attainable. Bourgeois-Pichat, in an attempt to estimate the effect on the life span of eliminating "exogenous" causes of death, obtained a maximum life expectancy of 76.3 for males and 78.2 for females. In 1978, he revised the limit, putting life expectancy for males slightly lower at 73.8 years and that for females higher, at 80.3 years (barely above the current estimates for Norway). Manton (1986) showed that an increase in life expectancy of 12.3 to 12.8 years in the expectation of life at age 30 years was possible with effective control of major risk factors. Even if no changes in mortality under 30 occurred this would result in an increase in male life span to above 81 years. On the basis of this evidence and given the long range nature of these projections a higher maximum life span was considered appropriate.

Future trends in life expectancy at birth.

Life expectancy is projected from year 0 to year t using a logistic function over time of the form

$$e_t = k_0 + k / \{1 + \exp [\text{logit}(e_0) + rt]\}, \quad \text{with} \\ \text{logit}(e_0) = \log_e [(k_0 + k - e_0) / (e_0 - k_0)].$$

Logistic functions are used because these fit past trends best, country by country. The schedules of medium change in life expectancy and infant mortality reflect median trends across countries, and the schedules for minimum and maximum change reflect the 10th and 90th percentile when country trends are ranked from slowest to fastest. The equations to predict short-term trends in life expectancy and infant mortality were estimated using these data; other socioeconomic factors, like per capita income, did not improve prediction.

The logistic function is set to rise most rapidly from a level of 50 years or so and increasingly slowly at higher levels. The minimum (k_0) for the logistic functions for both sexes is assumed to be 20 years, and the maxima ($k_0 + k$) are assumed to be 90 years for females and 83.3 years for males. The rate of change (r) for the logistic function is allowed to vary across countries, and for a given country to vary over time.

For the first quinquennium (1985-90), the rate of change (r_1) is estimated from the rate of change in the previous quinquennium (r_0) and from the female secondary enrolment ratio (s_0),

using the equations

$$r_1 = .00379 + .723 r_0 - .000254 s_0 \text{ for females, and}$$

$$r_1 = .01159 + .885 r_0 - .000318 s_0 \text{ for males.}$$

Percent urban is used in a few cases, with a different equation (see Bulatao et al., 1989), where secondary enrolment is not available, and in fewer cases still the rate of change in the previous decade is used instead of the rate of change in the previous quinquennium when the latter appears to have been affected by exceptional circumstances. Limits are imposed on the rate of change for the first quinquennium (and for all other quinquennia), such that it cannot be greater than -.017 (which would give slow mortality decline) or less than -.053 (which would give rapid mortality decline).

For the second quinquennium, the rate of change is estimated as a function of the rate of change for the first quinquennium:

$$r_2 = -0.007 + 0.7 r_1.$$

Table A1 Assumed annual increments to life expectancy

Initial life expectancy	Males			Females		
	Minimum	Medium	Maximum	Minimum	Medium	Maximum
40	0.14	0.34	0.55	0.14	0.36	0.58
45	0.15	0.38	0.61	0.16	0.40	0.65
50	0.16	0.39	0.63	0.17	0.43	0.69
55	0.16	0.39	0.62	0.17	0.44	0.70
60	0.15	0.37	0.59	0.17	0.43	0.68
65	0.13	0.32	0.52	0.16	0.40	0.69
70	0.10	0.26	0.42	0.14	0.36	0.57
75	0.07	0.18	0.28	0.12	0.27	0.47
80	0.03	0.08	0.12	0.09	0.21	0.34
85	--	--	--	0.05	0.11	0.18

The rate of change for the third quinquennium is estimated from the rate of change for the second quinquennium in the same manner. This equation allows rates of change to converge toward the uniform pattern imposed for subsequent quinquennia.

For these subsequent quinquennia for all countries, the rate of change in life expectancy is constant at -.035 for both sexes. At this rate, the annual increments to life expectancy vary by initial levels as indicated by the medium

pattern in Table A1. Minimum and maximum increments corresponding to the slow and rapid limits imposed on rates of change in the first three quinquennia are also shown.

Future trends in infant mortality.

Infant mortality is projected using a similar logistic function. The rate of change for each of the first three quinquennia is obtained from the equation

$$r_i = .0275 + .5 r_{i-1}$$

with the restriction that this rate must be in the range [.024, .130]. These limits provide schedules of minimum and maximum annual decrements to infant mortality, varying by the initial rate, shown in Table A2. A set of medium decrements is also provided, representing the typical schedule of improvements toward which rates of change converge when the preceding equation is applied successively. A minimum attainable level of infant mortality of 3 per thousand was used instead of the previously assumed 6 per thousand. This level is roughly equivalent to the level attainable under

Table A2 Assumed annual decrements to infant mortality rate

Initial infant mortality rate	Minimum	Medium	Maximum
150	0.83	2.08	4.02
140	0.92	2.32	4.47
130	1.00	2.50	4.81
120	1.13	2.63	5.03
110	1.16	2.69	5.15
100	1.16	2.71	5.16
90	1.14	2.66	5.07
80	1.10	2.56	4.86
70	1.03	2.41	4.56
60	0.93	2.20	4.16
50	0.81	1.94	3.65
40	0.67	1.62	3.05
30	0.50	1.26	2.35
20	0.31	0.84	1.56
10	0.09	0.36	0.68

the extended life expectancy assumptions employed.

Selection of life tables.

Those life tables are selected from the Coale-Demeny models (Coale and Demeny 1983) that provide the projected life expectancy and infant mortality rates for the first three quinquennia. First, a level of the life tables is chosen to give the desired infant mortality rate (interpolation is used if necessary). Mortality rates up to age 14 are taken from this life table. Second, another level of the life table is chosen to give rates for ages 15 and older such that the desired level of life expectancy is obtained. Among the four Coale-Demeny families (North, South, East, and West), that family is chosen which minimizes the divergence between the two chosen levels.

For subsequent quinquennia, only life expectancy is used in determining levels, and the

West family is used consistently.

Survivorship ratios from these model life tables were specified for the first three quinquennia and for 2025-30, 2050-55, and 2100-05. The projection program used, ProjPC-II (Hill, forthcoming), was allowed to interpolate linearly for intervening periods, to facilitate a smooth transition across life table families where this was necessary.

Projecting fertility

Future fertility trends are specified by quinquennial total fertility and by a year when the net reproduction rate reaches unity, i.e., when the average woman's fertility results in exactly replacing herself. (This is referred to here as the replacement year.) Separate procedures are applied for three stages of the fertility transition: the pretransition stage, when fertility is high and sustained fertility decline has not started; the transition stage, when fertility is high to medium and sustained fertility decline is in progress; and the late-transition and posttransition stage. We discuss procedures for determining total fertility in each stage and then explain what age-specific patterns of fertility were applied.

For current purposes, a fertility transition is assumed to have started if a country has experienced a drop in total fertility of at least .5 points over any five-year period, or if total fertility is already below 4.5 after a more gradual decline (Bulatao and Elwan 1985). The pretransition stage is the stage before any such decline is evident. The late-transition and posttransition stage is defined by a total fertility rate one point above replacement level (about 3.15) or lower.

Countries in the pretransition stage are assumed to start a fertility transition in the quinquennium after combined male and female life expectancy reaches 50 years, but in no case later than 2005. The life expectancy threshold is slightly lower than the threshold of 53 years previously shown to be a universal precondition, though not a sufficient condition, for the start of fertility transition (Bulatao and Elwan 1985). Until a transition starts, total fertility is assumed to be constant. The one exception is where sterility is a significant factor; sterility is then assumed to decline linearly

to 6 percent over three quinquennia, with each percentage point drop in sterility raising total fertility by .11 points (Frank 1983).

In the transition stage, the rate of fertility decline is based on the rate in the preceding quinquennium, assuming transition had already started in that period. With previous annual change represented by D_{TFR} , annual change during the transition is set at $(-.05 + .5 D_{TFR})$. However, limits are set on this change: it must be at least -.073 points and at most -.210 points, which may be taken to define slow and rapid fertility decline. (Previous analysis in Bulatao and Elwan 1985 defined rapid decline as an annual total fertility change of -.2164 points, which is consistent.) If the formula does not apply because transition has just started, an average annual decline in total fertility of .06 points for the first five year of the transition and 0.12 annually for subsequent quinquennia is imposed. In the early part of the transition stage, the sterility adjustment is applied if appropriate to raise total fertility slightly.

In the late-transition and posttransition stage, fertility approaches replacement level, either from slightly above or slightly below it. Four alternative patterns:

- Generally, a geometric function is imposed on total fertility decline from one point above replacement level to replacement level, with this decline assumed to take 15 years.
- Where total fertility has shown unusually slow decline, it is assumed to take 20 rather than 15 years for total fertility to fall one point to replacement.
- Where, toward the end of a fertility transition, total fertility is still recording rapid declines even though it is close to or even below replacement level (2.25 to 1.75), it is assumed to fall further for one period, generally going below replacement, to stay constant in the next period, and then to return to replacement.
- Where the transition has been completed and total fertility is below replacement, it is assumed to stay at the current level for two quinquennia, and then to return gradually to replacement, along a linear path, by 2030.

In applying late-transition procedures, the level of total fertility that provides replacement is approximated by a quadratic formula based on female life expectancy ($e_{(t)}$) in the replacement year:

$$TFR_{NRR=1} = 6.702 - .1107 e_{(t)} + .0006592 e_{(t)}^2.$$

The replacement year is first approximated in order to determine life expectancy and then calculated given this formula and whichever pattern of fertility change above is appropriate.

For all stages of fertility transition, the age pattern of fertility is determined in the same fashion, depending on the level of total fertility (Figure A2). Two basic schedules of age-specific fertility are defined: for total fertility levels greater than six and for total fertility levels of three and lower. In between, age patterns are obtained by interpolation between the two schedules. At a total fertility level of six, a greater proportion of births are at younger and older ages of the reproductive span, and the mean age of childbearing is 28.9 years. At a total fertility level of three, births are concentrated in a narrower band of ages, and the mean age of childbearing is 28.0.

These procedures were developed from preliminary analysis of total fertility trends in cross-national data (See Bos and Bulatao 1989). In the pretransition stage, countries showed mostly stable fertility. The transition stage was more interesting. Across 42 countries which started a fertility transition between 1955 and 1983, the average annual decline in total fertility ranged from 0.06 to 0.25

Figure A2. Percentage of Total Fertility Assigned to Different Ages, by Level of Total Fertility

points. Countries which had initial sharp declines in fertility tended to continue declining rapidly, while those that started with more gradual declines continued along the same path. Rapid and slow decline were found in all regions. The rate of decline was predicted best by the rate in preceding periods; socioeconomic factors added little to this prediction. Other than the mortality threshold, socioeconomic factors also failed to predict the start of fertility transition.

Projecting Migration

Estimates of future net migrants by quinquennium up to the year 2000 are those prepared by Arnold (1989) as part of an examination of data and sources. These estimates are strongly affected by official policies and plans in the major receiving countries. The figures were designed to total zero in each quinquennium for the whole world. After the year 2000, the number of net migrants is assumed to approach zero linearly in each country, at the estimated rate of change in their number from the period 1990-95 to the period 1995-2000, or at a rate that would make their number zero by 2025-30, whichever rate is faster. For these later periods, a zero total for worldwide net international migration was obtained by adjusting initial estimates of net migrants in three major receiving countries--the United States, Australia, and Canada--upward or downward as necessary by a proportion constant across these countries, but varying by quinquennium. These adjustments were of 1 or 2 percent for the earlier periods, negligible compared to the volume of migration assumed for these countries, but were up to 10 percent for later periods.

The age-sex distributions of migrants are determined from alternative models based on their sex ratios. If migration is heavily male, migrants are assumed to be concentrated in the age group 15-30, with few children and elderly. If migration is more balanced between males and females, proportionally more migrants are assumed to be children and elderly (Hill, 1990).

ADDENDUM

This section was produced after the projections were completed, just before the papers were issued. Its purpose is to list the results of censuses and surveys that came to our attention too late to be incorporated. *Note* that these are usually preliminary results that have not been evaluated for data quality, i.e., undercounts in censuses or sampling errors in surveys. Differences with the estimates in the main tables in this volume are therefore not necessarily inconsistencies.

Bolivia: Preliminary result of June 1992 census gives total population of 6.3 million.

Djibouti: Intercensal survey (EDI) of 1991 gives total population of 519,900.

Malaysia: Preliminary result of the August 1991 census is 17,566,982 persons. Underenumeration in the 1980 census was estimated at 4.4 percent.

Nigeria: Preliminary result of the November 1991 census shows a total of 88,514,501 million people.

Pakistan: Integrated Household Survey (PIHS) of 1991 estimates the IMR at 121 for 1986-90.

Peru: Preliminary estimates from the 1991-92 Encuesta Demográfica y de Salud Familiar (ENDES-DHS) shows the IMR at 55 for the five-year period preceding the survey and the TFR at 3.5 for the three years preceding the survey.

Zambia: Preliminary estimates from the Demographic and Health Survey (ZDHS) of 1992 show the IMR at 108 for the five-year period preceding the survey and the TFR at 6.3 for the three years preceding the survey.
