

The Quality of Bureaucracy and Capital Account Policies

Chong-En Bai
Shang-Jin Wei

The more corrupt a country, the more likely it is to impose capital controls. As a country improves its public institutions over time, it tends to gradually liberalize its capital accounts. Removing capital controls prematurely could reduce rather than improve the country's economic efficiency.

Summary findings

The extent of bureaucracy varies extensively across countries, but the quality of bureaucracy within a country changes more slowly than economic policies. Bai and Wei propose that the quality of bureaucracy may be an important structural determinant of open economy macroeconomic policies—especially the imposition or removal of capital controls.

In their model, capital controls are an instrument of financial repression. They entail efficiency loss for the economy but also generate implicit revenue for the government. The results show that bureaucratic corruption translates into the government's reduced ability to collect tax revenues. Even if capital controls and financial repression are otherwise inefficient, the government still has to rely on them to raise revenues to provide public goods.

Among the countries for which the authors could get relevant data, they find that the more corrupt ones are indeed more likely to impose capital controls, a pattern consistent with the model's prediction. To deal with possible reverse causality, they use the extent of corruption in a country's judicial system, and the degree of democracy, as the instrumental variables for bureaucratic corruption. The instrumental variable regressions show the same result: more corrupt countries are associated with more severe capital controls.

The results suggest that as countries develop and improve their public institutions, reducing bureaucratic corruption over time, they will choose to gradually liberalize their capital accounts. Removing capital controls prematurely when forced by outside institutions to do so could reduce rather than improve their economic efficiency.

This paper—a product of the Development Research Group—is part of a larger effort in the group to understand the consequences of corruption and public governance. Copies of the paper are available free from the World Bank, 1818 H Street NW, Washington, DC 20433. Please contact Hedy Sladovich, room MC2-609, telephone 202-473-7698, fax 202-522-1154, email address hsladovich@worldbank.org. Tamirisa for some of the data. The views in the paper are the authors' own, and may not be shared by the World Bank or any other organization that we are associated with.

1. Introduction

The quality of bureaucracy varies widely across countries. This paper examines the role of bureaucratic quality in open-economy macro policies, with a specific focus on the imposition of capital controls and financial repression.

Capital controls and financial repression in developing countries were once considered a severe hindrance to economic development (McKinnon, 1973; and Shaw, 1973). In the aftermath of the 1997-98 Asian economic crisis, an interesting twist in the intellectual wisdom is emerging. Most economists now believe that capital account liberalization without a proper domestic financial supervisory and regulatory structure in place is a recipe for financial disasters. Several prominent economists go step further, arguing that the benefits of capital account liberalization are probably negligible (e.g., Rodrik, 1999), or that restrictions on capital movement can serve useful policy functions if one believes that international portfolio flows and short term credits are excessively volatile (Wyplosz, 1986; Rodrik, 1999; Rodrik and Velasco, 1999).

We look at capital controls/financial repression from a different angle, namely, bureaucratic quality as a potential determinant. An important, but sometimes less appreciated, fact is that the quality of bureaucracy evolves slowly relative to the speed with which a government can implement many economic policies, such as imposing or removing capital controls. In a country with widespread bureaucratic corruption, the government loses the ability to collect fiscal revenues from formal tax channels. Or more precisely, the marginal cost of collecting tax revenues rises with the level of corruption. As a consequence, it would have to rely increasingly on the otherwise inefficient capital control/financial repression to finance the provision of public goods. In this case, a premature removal of capital controls (a possible mandate by the International Monetary Fund) could reduce rather than enhance economic efficiency. This is a separate point from the possibility that a premature removal of capital controls may increase the likelihood of a financial crisis.

Two relevant strands of the literature examine this issue. The first strand examines the consequences or determinants of bureaucratic corruption (Rose-Ackerman (1978), Shleifer and Vishny (1993), Mauro (1995), Ades and Di Tella (1997 and 1999),

and Wei (1997)¹). The second strand examines the consequences or determinants of capital controls (Alesina and Tabellini (1989), Epstein and Schor (1992), Dellas and Stockman (1993), Dooley and Isard (1980), Lane and Rojas-Suarez (1992), Mathieson and Rojas-Suarez (1993), Alesina, Grilli and Milesi-Ferretti (1994), Aizenman and Guidotti (1994), Bartolini and Drazen (1997), and Grilli and Miles-Ferretti (1995).

As far as we know, none of these papers looked directly at the connection between corruption and capital controls. Of course, those papers emphasizing the public finance motivation for capital controls are direct predecessors to this paper. Our contribution is to argue (and to provide the first model and first piece of evidence) that bureaucratic corruption may be the underlying reason for the difficulty in tax collection and, as a result, greater reliance on capital controls.

It is possible that the existence of capital controls breeds corruption as firms/individuals find it necessary to pay bribes in order to circumvent the control. Indeed, we need to take into account this possibility in the empirical examination. The central focus of this paper is on the reverse question, How is the imposition and severity of capital controls affected by the extent of corruption in the country? In other words, we take the extent of bureaucratic corruption as an exogenous “state of nature,” in the sense that it is part of the public institutional infrastructure that is slow to evolve. More precisely, it is assumed that a government or top political leader can impose/remove capital control or change its severity much more swiftly than altering the extent of bureaucratic corruption in the country.²

The term “bureaucratic corruption” we use encompasses various dimensions of the quality of bureaucracy, including government efficiency and burden of regulation, and not just bribe-taking by officials. Unfortunately, we have no direct measures of these dimensions. What we can feasibly gather are measures of bureaucratic corruption based on the perceptions of experts, firm managers, or citizens. Our suspicion is that the different dimensions of bureaucratic quality are highly correlated. Nonetheless, it is useful to keep this broad perspective in mind when interpreting our results.

¹ See Pardhan (1997) <add to refs> and Wei (2000) for a more complete review of the literature.

² A possible extension of the model is to allow corruption and capital controls (or policy distortions in general) to influence each other, possibly leading to multiple equilibria.

Our paper is organized in the following way. Section 2 presents a model that formalizes our story. Section 3 describes the data used in the empirical analysis. Section 4 reports the empirical evidence on our hypothesis. Section 5 concludes.

2. A Theoretical Model

In our theoretical model capital control is endogenously determined by the government in a way that is related to the level of corruption in the country. A welfare-maximizing government (top leader) collects revenue to provide public goods, but our central story applies if the top leader simply collects revenue for her private consumption.

2.1 Setup of the Model

We consider a model with a representative investor in the private sector, a bureaucrat, and a government. The representative private investor's utility increases with the amount of the public good provided by the government, denoted by X , as well as his private consumption, denoted by Y , whose price is normalized to be one. Specifically, we assume that the expected utility function is

$$U_p = E\{-e^{-\delta Y - \gamma X}\},$$

where $\delta > 0$ and $\gamma > 0$.

The investor is endowed with a fixed wealth Y_0 . His consumption depends on tax T and investment opportunities. We assume that he can invest his net wealth $Y_0 - T$ in a portfolio of domestic and foreign assets. Denote the return to the domestic asset by R_d and that to the foreign asset by R_f . The two returns can be different for reasons we will discuss later. Suppose the investor allocates α share of his net wealth to the foreign asset. Then his consumption will be

$$Y = (Y_0 - T)[\alpha R_f + (1 - \alpha)R_d].$$

For simplicity, let us say that both the domestic and foreign assets are risk free. In the absence of capital controls, both are equal to the world interest rate, $R_f = R_d = r^*$. Of course, in this case, the representative domestic agent is indifferent between domestic and foreign assets, and the optimal α is undetermined.

In this model, we recognize that capital control is an instrument of financial repression. It has two effects. First, because circumventing capital control is costly, it reduces the rate of return on investing abroad that is available to domestic investor, so that now $R_f < r^*$. Second, because circumventing capital control runs the risk of being caught and punished, the effective rate of return on the foreign asset faced by the domestic agent now becomes risky, and in equilibrium would on average be somewhat higher than the domestic (still risk-free) interest rate, $E\{R_f\} > R_d$. To be simple and concrete, we will assume (rather than derive) a specific functional form linking the extent of capital control, denoted by k , and the equilibrium domestic and foreign rates of return

$$R_d = r^* - \rho k$$

$$R_f = r^* - \rho k + \rho_f k + kv$$

where ρ is the effectiveness of capital control, v is a random variable with a normal distribution $N(0, \sigma^2)$ and represents the risk that capital control causes to investing in foreign assets, and ρ_f indicates that capital control is less effective in depressing the return to foreign assets than to domestic assets. Ideally, we should assume a distribution for the random variable, v , which is bounded from above. For simplicity, we make it an unbounded normal variable.

The amount of public good provided by the government, X , depends on its available resources, denoted by Z .

$$X = f(Z),$$

where f is an increasing and concave function.

The government raises tax T . Corruption results in part of the tax revenue being stolen by the bureaucrat. Suppose the bureaucrat's stealing is

$$S = S(T, \theta)$$

where θ is a parameter representing the weakness of governance, or the degree of corruption.

We assume that S is increasing in T and θ respectively and is convex in T . Furthermore, $S_{T\theta} > 0$. In other words, as either the total amount of tax or corruption increases, stealing by bureaucrats also increases. Furthermore, as either total tax or corruption increases, marginal stealing per unit of tax collected also increases. In

Appendix A, we offer a plausible justification for these assumptions. We label the fraction of formal taxes that disappears as “stealing” by the corruption-prone bureaucrats. Alternatively, we could also interpret it as “waste” of government resources by the inefficient and corrupt bureaucrats.

The government’s total usable fiscal resources, Z , consist of two components: an explicit tax revenue net of stealing (or waste), and an implicit tax revenue derived from financial repression. One possible example of implicit revenue is the saving by the government in its cost of borrowing from the domestic capital market when the domestic interest rate is artificially suppressed to below the world interest rate.³ We assume that the implicit revenue from the financial depression depends on the reduction in domestic interest rate as a result of capital controls, ρk , and the total amount of domestic savings, $(Y_0 - T)$. Then,

$$Z = [T - S(T, \theta)] + [\phi \rho k (Y_0 - T)].$$

In Appendix C, we employ an alternative assumption in which the implicit tax revenue is $\phi \rho k (1 - \alpha)(Y_0 - T)$. In other words, it depends only on the amount of domestic savings that is not invested abroad. We show that while this complicates the mathematical derivations, the basic qualitative conclusion of the model is still the same.

We consider a sequential game in which the government moves first, choosing explicit tax T and the degree of capital control k to maximize the social welfare, taking as given the weakness of the public institution (i.e., the extent of corruption), the bureaucrat’s stealing function, and the private investor’s reaction function. The representative private investor moves next, choosing an optimal allocation between capital flight and domestic investment, taking into account the tax and capital control. We solve the game with backward induction.

2.2 The Private Investor’s Decision

Given his portfolio choice α , the private investor’s consumption is

$$Y = (Y_0 - T)(r^* - \rho k + \alpha \rho k + \alpha k v).$$

³ One could also think of seigniorage revenue as another source of implicit revenue. Giovannini and de Melo (1993) made a conceptual distinction between financial repression and seigniorage, but also showed that the two are positively correlated across countries.

Then, his expected utility is

$$-e^{-\gamma X} e^{-\delta CE},$$

where

$$CE = (Y_0 - T)(r^* - \rho k + \alpha \rho_f k) - 0.5 \delta \alpha^2 k^2 (Y_0 - T)^2 \sigma^2$$

is his certainty equivalent consumption level. Then, an expected utility maximizing investor should choose α to maximize CE. The first-order condition for α is

$$(Y_0 - T) \rho_f k - \delta \alpha k^2 (Y_0 - T)^2 \sigma^2 = 0$$

and the optimal choice of α is

$$\alpha^* = [k \rho_f] / [\delta k^2 \sigma^2 (Y_0 - T)] = \rho_f / [\delta k \sigma^2 (Y_0 - T)].$$

α^* is the proportion of after-tax wealth invested in foreign assets, or the extent of capital flight. The above equation implies that capital flight decreases with the risk of the flight, $k^2 \sigma^2$ and with the rate of risk aversion, δ , but increases with the premium of investing aboard, $k \rho_f$

Given the optimal portfolio choice α^* , the private investor's utility level is

$$U_p^* = -\exp\{-\gamma f[T - S(T, \theta) + \phi \rho k (Y_0 - T)] - \delta (Y_0 - T)(r^* - \rho k) - 0.5 \rho_f^2 / \sigma^2\}.$$

2.3. The Government's Decision

The government chooses k and T to maximize the above utility level of the representative private investor, or equivalently, the government maximizes

$$U_g(k, T) = \gamma f[T - S(T, \theta) + \phi \rho k (Y_0 - T)] + \delta (Y_0 - T)(r^* - \rho k) + 0.5 \rho_f^2 / \sigma^2.$$

Lemma 1: *Suppose $\phi r^* < 1$ and θ is not too small. Then, the optimal T is determined by*

$$S_T(T, \theta) = 1 - \phi r^* \tag{1}$$

and the optimal k is determined by

$$T - S(T, \theta) + \phi \rho k (Y_0 - T) = (f')^{-1}[\delta / (\gamma \phi)]. \tag{2}$$

Proof: The government's objective function U_g is not necessarily concave in T .

Therefore, it is not clear whether or not the first-order conditions of the optimization problem are sufficient. To circumvent this problem, we maximize the objective function in two steps.

First, for any given T , U_g is a concave function of k and the optimal k satisfies the first-order condition

$$\gamma f'[T - S(T, \theta) + \phi \rho k(Y_0 - T)] \phi \rho(Y_0 - T) - \delta \rho(Y_0 - T) = 0,$$

or

$$\gamma f'[T - S(T, \theta) + \phi \rho k(Y_0 - T)] \phi - \delta = 0,$$

which implies

$$T - S(T, \theta) + \phi \rho k(Y_0 - T) = (f')^{-1}[\delta/(\gamma \phi)] \equiv Z^*.$$

Then, the government's problem becomes maximizing U_g subject to the above first-order condition for k ; that is,

$$\text{Max}_T U_g(k, T) = \gamma f[T - S(T, \theta) + \phi \rho k(Y_0 - T)] + \delta(Y_0 - T)(r^* - \rho k) + 0.5 \rho_f^2 / \sigma^2$$

$$\text{subject to: } T - S(T, \theta) + \phi \rho k(Y_0 - T) = Z^*.$$

From the constraint,

$$\rho k(Y_0 - T) = [Z^* - T + S(T, \theta)] / \phi.$$

Substitute the above equation into U_g . Then

$$U_g(T) = \gamma f(Z^*) + \delta r^*(Y_0 - T) - \delta \rho k(Y_0 - T) + 0.5 \rho_f^2 / \sigma^2$$

$$= \gamma f(Z^*) + \delta r^*(Y_0 - T) - \delta [Z^* - T + S(T, \theta)] / \phi + 0.5 \rho_f^2 / \sigma^2.$$

By the assumption that $S(T, \theta)$ is convex in T , the reduced form of U_g is concave in T .

Then the optimal T is determined by the first-order condition that

$$U_g'(T) = -\delta r^* + \delta / \phi - \delta S_T(T, \theta) / \phi = 0,$$

or

$$S_T(T, \theta) = 1 - \phi r^*.$$

Q.E.D.

Remark 1: If ϕ is so large that $1 - \phi r^* < 0$, or in other words, if financial repression is very effective at raising revenue for the government, the optimal $T = 0$. To see this, note that $U_g'(T) < 0$ for all T if $1 - \phi r^* < 0$.

Remark 2: Suppose $1 - \phi r^* > 0$. If corruption is negligible and hence stealing by the bureaucrat is negligible, then it is optimal not to have any capital control. Specifically, if θ is so small that $S_T(T, \theta) < 1 - \phi r^*$ for all $T < Y_0$, then $U_g(T) > 0$ for all $T < Y_0$ and it is optimal to choose T large enough to fulfill the need for public good provision and to choose $k = 0$.

The lemma implies that both direct taxation and capital control are used for the government to obtain resources to finance public good provision. The intuitive reason for this mixture to be optimal is as follows. The stealing function $S(T, \theta)$ is concave in T . Therefore, the marginal cost of T increases. On the other hand, the marginal cost of capital control – depressed return to investment – is a constant. Then, the marginal cost of T is higher than that of k when T is too high, and is lower when T is too low. As a result, only part of the expenditure for public good provision should be financed by direct taxation T .

2. 4. Comparative Statics

Proposition 1: *The optimal capital control k increases with the level of bureaucratic corruption θ , while the optimal tax collection T decreases with the corruption level θ .*

The proofs for this proposition and the next are provided in Appendix B. The results in Proposition 1 are not difficult to understand intuitively. As corruption increases, more tax revenue will be stolen, then it is more desirable to finance the public good by capital control/financial repression rather than by direct taxation.

Proposition 2: *(i) The optimal tax T is independent of the degree of risk aversion ρ but the optimal capital control k decreases with ρ . (ii) The optimal tax T decreases with ϕ but the relationship between the optimal k and ϕ is ambiguous. (iii) The optimal T is independent of γ and δ , but the optimal k increases with γ and decreases with δ , where γ is the importance of the public good in the representative private investor's utility while δ is that of private consumption. (iv) The optimal T and k are both independent of ρ_f and σ .*

Intuitively, as ρ increases, the returns to investment decrease, and the government resources from capital control increase, at the same proportion. This implies that the level

of public good provision and T should not change. With the increase in the government's ability to extract resources from capital control, there is less need for the control in order to obtain the given level of resources for public good provision; that is the optimal k decreases. This is the reason for part (i) of Proposition 2.

The intuition for (ii) is as follows. As ϕ increases, the government can get more resources from capital control and therefore has less need for direct taxation, resulting in lower T . The increase in ϕ has two effects on k . The positive one (similar to the substitution effect) is that more resources should be extracted from capital control and the negative one (similar to the income effect) is that less control is needed in order to extract a given level of resources. It is not clear which one of these effects dominate.

As the public good becomes more important to the investor's utility relative to private consumption, i.e., as γ increases or δ decreases, the benefit of capital control – increasing the resources available for public provision – becomes larger and the cost of capital control – decreasing the returns to private investment – becomes smaller. Therefore, k should increase. The effect of γ and δ on T is not so straightforward. When the public good becomes more important, it seems that more tax should be levied to increase public good provision. A larger T , however, reduces the opportunity for the government to obtain resources from capital control, thus reducing public good provision. The two effects of T happen to cancel with each other in this model. As a result, the optimal T is independent of γ and δ . This is the reason for (iii).

To understand (iv), note that ρ_f and σ^2 enter into the government's objective function $U_g(k, T)$ only through a term that is independent of k and T . Therefore, the marginal effects of k and T on $U_g(k, T)$ are independent of ρ_f and σ^2 . Consequently, the optimal k and T are both independent of ρ_f and σ^2 .

3. Data

The detailed definition and source for the data as well as their manipulation are explained in Appendix D. Here, we provide a brief description on the most important variables in our empirical analysis.

3.1 Capital Control

Our capital controls are derived from the annual issues of the IMF's into five categories of restrictions on foreign exchange transactions that the IMF has consistently coded throughout our sample, 1984-1997. They are (1) existence of multiple exchange rates, (2) payment arrears and bilateral payments arrangement, (3) controls on payments for invisible transactions and current transfers, (4) controls on proceeds from exports and/or invisible transactions, and finally, (5) controls on capital account transactions. For each category, the IMF source indicates whether the country has restrictions or not.

We derive a discreet-valued measure of the severity of capital control by aggregating the five categories. Thus, the measure can take one of the six values from zero to five, zero being no controls in any of the five categories, and five being controls in all five categories. For exact definitions of the six categories see Appendix B.

3.2 Bureaucratic Corruption

We use four different measures of corruption: ICRG, GCR, WDR, and TI indexes. In addition, we use two variables as instrumental variables for corruption: legal corruption and democracy.

(A) International Country Risk Guide (ICRG) Index.

The ICRG corruption index has been produced every year since 1982 by Political Risk Services, a private international investment risk service. The ICRG index is apparently based on the opinion of experts and supposedly captures the extent to which "high government officials are likely to demand special payments" and the extent to which "illegal payments are generally expected throughout lower levels of government" in the form of "bribes connected with import and export licenses, exchange controls, tax assessments, police protection, or loans."

(B) Global Competitiveness Report (GCR) Index

Unlike the ICRG indices, the GCR index is based on a 1996 survey of firm managers, rather than experts or consultants. This survey, sponsored by the World Economic Forum (WEF), a Europe-based consortium with a large membership of firms,

and designed by the Harvard Institute for International Development (HIID), asked the responding firms about various aspects of “competitiveness” in the host countries where they invest. The question on corruption asked the respondents (2,381 firms in 58 countries) to rate the level of corruption on a one-to-seven scale according to the extent of “irregular, additional payments connected with import and export permits, business licenses, exchange controls, tax assessments, police protection or loan applications.” The GCR corruption index for a particular country is the average of all respondents’ ratings for that country.

(C) World Development Report (WDR) Index

Similar to the GCR index, the WDR index is based on a 1996 survey of firms conducted by the World Bank for its 1997 World Development Report. Respondents were asked a long list of questions, including one on perceived level of corruption. The question is essentially identical to the one in the GCR survey. The WDR survey covers over 70 countries (many of which are not in the WDR sample, and the reverse is also true). The WDR survey tends to cover more medium and small firms whereas the GCR survey covered larger firms.

(D) Transparency International (TI) Index

The TI index has been produced annually since 1995 by Transparency International, an international non-governmental organization dedicated to fighting corruption worldwide. This index is based on a weighted average of approximately 10 surveys of varying coverage. It ranks corruption in countries on a one-to-ten scale.

As a survey of surveys, the TI index has advantages and disadvantages. If the measurement errors in different surveys are independent and identically distributed (iid), the averaging process used to produce the TI index may reduce the measurement error. But the iid assumption may not hold. Moreover, since different surveys cover different subsets of countries, the averaging process may introduce new measurement errors when cross-country rankings are produced. Because the TI indexes in different years are derived from potentially different set of surveys, they should not be used to measure changes in corruption level over time for a particular country.

(E) First IV for Corruption: Democracy

Democracy is measured by adding up an index for civil liberties and another for political rights. The Freedom House composes both indexes. The liberties index measures the extent to which people are able to express their opinion openly without fear of reprisals and are protected in doing so by an independent judiciary. Although this index reflects rights to organize and demonstrate, as well as freedom of religion, education, travel and other personal rights, more weight was given liberties most directly related to the expression of political rights. This variable is an index and not in logs.

The political rights index measures meaningful participation in the political process on a scale of one to seven where lower numbers indicate greater political rights (see Gastil, 1989). A high-ranking country must have a fully operating electoral procedure, usually including a significant opposition vote. It is likely to have had a recent change of government from one party to another, an absence of foreign domination, decentralized political power and a consensus that allows all segments of the population some power. The index was constructed on the basis of satisfaction of the above and other related criteria by the countries in question. This variable is an index and not in logs.

Both indexes use a range from 1 to 7. A smaller number means a higher degree of freedom. Democracy is defined as $(7-civ)+(7-pol)$.

(F) Second IV Variable for Bureaucratic Corruption: Corruption in the Judicial System

A measure for corruption in a country's judicial system is based on the same GCR survey that produced the GCR bureaucratic corruption measure. Survey question 8.09 asked the respondents to rate the level of corruption in the judicial system based on the extent to which "[i]rregular payments to judges or other officials involved in the enforcement and execution of judgements are not common and do not influence the outcome of court proceedings" (1=strongly disagree, 7=strongly agree). We rescaled the index $(7 - \text{original score})$ so that a larger number means more corrupt judicial system.

Tables 1a and 1b report summary statistics for the key variables and their pairwise correlations.

4. Statistical Analysis

Since our measure of capital controls can take six discrete values from a minimum of zero to a maximum of five, we employ an ordered Probit specification:

Capital Control in Country $j = k$

if $D_k < Y_j^* \leq D_{k+1}$

where $Y_j^* = \theta \text{Corruption}_j + X_j \beta + e_j$

$k = 0, 1, 2, \dots, 5$; $D_0 = -\infty$. and $D_6 = \infty$; D_1, \dots, D_5 are parameters estimated together with scalar θ and vector β ; X is a vector of control variables other than corruption; and e_j is an independently and identically distributed normal variate with a zero mean.

Table 2 presents simple regressions of the measure of capital control severity on corruption and a dummy indicating membership in OECD. OECD membership in recent years often requires capital account liberalization (which was the case when Mexico and Korea obtained their membership in 1994 and 1996, respectively). The first four columns use four different measures of corruption: TI, GCR, WDR and ICRG, respectively. In each of these regressions, the extent of capital controls is positively related to the countries' perceived level of corruption.

By using the ICRG corruption measures for 1982-96, we implemented a quasi-fixed-effects panel regression where year and region dummies are included as additional regressors. The result is reported in Column 5. The coefficient on the ICRG-corruption measure is smaller than the corresponding one in the cross-section regression in Column 4. But it remains positive and significant at the 10 percent level, again consistent with the hypothesis that capital controls are more likely in more corrupt countries.

One may be concerned that the four measures of corruption so far can be tainted by reverse causality. More precisely, since illegal/irregular payments made to circumvent exchange controls are part of the criteria used to assess the degree of corruption, in a very direct sense, countries with more severe capital controls would also be rated as more corrupt. To deal with this, we employ an instrumental variable related to the extent of corruption in a country but (arguably) not directly a consequence of

capital controls. Two such variables are considered. The first measures corruption in a country's judicial system. When a country's legal system is corrupt, corrupt officials are less likely to be punished. The second variable measures the degree of democracy (civil liberties and political rights). Democracy enhances accountability. Lack of democracy breeds corruption and embezzlement. Neither legal corruption nor democracy is likely to be directly influenced by the imposition or severity of capital controls.

In the last column of Table 2, we use these two variables as instruments for the GCR-corruption measure. As we can see, the point estimate on corruption is somewhat smaller than the corresponding regression without the IVs (column 2, Table 2). However, the coefficient remains positive and statistically significant. So this is stronger evidence that more corrupt countries are more likely to impose capital controls.

In Table 3, we add three regional dummies to the regression (in addition to the OECD membership dummy). Sub-Sahara African countries always have a positive sign in all six regressions (indicating a tendency to have more severe capital controls), whereas East Asian and Latin American countries mostly have a negative sign (indicating a tendency to have less controls). However, for each regional dummy, the coefficient is often insignificantly different from zero in many specifications. The most important observation for our purpose is that the coefficient on corruption remains positive in all specifications and significant in five out of six specifications (including one in which corruption is instrumented by legal corruption and democracy).

Grilli and Miles-Ferretti (1995) and Miles-Ferretti (1998) have argued that government consumption-to-GDP ratio and government debt-to-GDP ratio are proxies for a government's preference for spending. This could be perfectly consistent with our theoretical model: other things constant, if the government prefers to spend more money, it would want to collect more revenues both from the formal tax channel and simultaneously from the financial repression channel with tightened capital controls.⁴ In addition to the government's preference for spending, these authors also propose proxies for the (marginal) cost of capital controls. In particular, they argue that an independent central bank makes it difficult for the government to rely on seigniorage revenue, and

⁴ In our model, the equilibrium capital control, k , rises with an increase in the relative importance of the public goods in the government's objective function, γ/δ . See Proposition 2 in the model section.

hence reduces its incentive to impose capital controls. Following Cukierman, Edwards and Tabellini (1992), they use an index of legal independence of central banks and a count of average annual turnover rate of the central bank governors as two measures of central bank independence. Related to this, the rate of inflation can be a more direct measure of the degree of financial repression the government is willing to exercise. These authors argue further that a government experiencing a current account deficit is less likely to impose capital controls.

One could argue that most of the variables used by these are also related to the underlying corruption in a country in a way that is consistent with our model. For example, rather than viewing central bank independence as exogenous, a corrupt country may be more inclined to choose a non-zero inflation rate and at the same time not to have an independent central bank.⁵

In any case, as a robustness check, we include these variables in our specification as additional regressors. The results are reported in Table 4. Since the number of countries with non-missing values for these variables is small (among those countries that also have corruption measures), we have between 23-30 observations in the current regressions, less than half than the corresponding regressions in Tables 2 and 3. In the first three columns of Table 4, where a different measure of corruption is used in each column, we see evidence that countries with high government consumption-to-GDP ratios also tend to impose capital controls. However, our regressions do not support the association between current account deficit, high inflation, and high government debt-to-GDP ratios tend and more severe capital controls (once corruption and other variables are taken into account). In fact, the signs on the coefficients for inflation and government debt are negative. Importantly, even in this very small sample, the corruption measure continues to exhibit a positive and statistically significant sign.

Using the ICRG measures of corruption, we experiment with two versions of panel regressions. The first is a quasi-fixed effects regression in which regional dummies in addition to year dummies are included. The second is a random-effects regression in which random country effects in addition to year dummies are included. In the first panel

⁵ See Huang and Wei (2000) for a model and some evidence.

regression, there is some support for a positive association between inflation and capital controls. In both regressions, corruption continues to enter positively and significantly.

Finally, when we use the extent of legal corruption and the degree of democracy as instruments for general corruption (the last two columns), we find that the coefficients on corruption are positive and statistically significant. Therefore, even in a small sample such as this and with more control variables, there is robust evidence that more corrupt countries are more likely to impose capital controls.

Since 1997, the IMF's *Annual Report on Exchange Arrangements and Exchange Restrictions* (AREAER) has given substantially more detailed information on a country's restrictions on up to 50 items of capital account transactions (and similarly detailed information on restrictions on current account transactions). This in principle would enrich our analysis. However, the tradeoff is that such detailed information is only available for 41 countries, many of which do not have data on corruption ratings. Given our already small number of countries in the sample, this could be a significant cost.

In any case, we relate two separate measures of current account and capital account restrictions based on the detailed information to the measures of corruption in Tables 6 and 7. The results are interesting. When the dependent variable is current account restrictions, the coefficient for corruption is insignificant in four out of five regressions (Table 6). However, when the dependent variable is capital account restrictions, corruption has a positive and significant coefficient in three out of five regressions including the one with instrumental variables (Table 7). To the extent that it is primarily the capital account restrictions rather than current account restrictions that generate financial repression in the country, these findings are also consistent with our hypothesis.

As a cross-validation, we take a look at our hypothesis from a different perspective. Our model's central story is a revenue loss story: the government has difficulty in collecting revenue through formal tax channels and hence has to rely more on capital controls and financial repression. Therefore, one would think that if tax evasion in a country can be measured, it should be positively correlated with corruption. In the Global Competitiveness Report survey, respondents were asked to assess the extent of tax evasion in the country. We use the mean response for each country as a

(subjective) measure of the extent of tax evasion. In Table 8, we regress tax evasion on corruption and statutory tax rate. We find that tax evasion is more pervasive in a country with a higher tax rate and a high level of corruption, exactly as our hypothesis would suggest.

5. Conclusion

This paper studies bureaucratic corruption as a determinant of capital controls. In our model, capital control is an instrument of financial repression. While it entails efficiency loss for the economy, it also generates implicit revenue for the government. The more severe the bureaucratic corruption in a country, the more difficult it is to collect formal taxes. As a result, the government has to rely more on capital controls/financial repression. In cross-country regressions, we find that more corrupt countries, measured by any of the four corruption indexes, or instrumented by the degree of democracy and legal corruption in a country, tend to impose more severe capital controls.

If our story is true, then as countries gradually develop better public institutions along their development trajectory, including reducing bureaucratic corruption over time, they will choose to gradually liberalize their capital accounts. However, a premature removal of capital controls forced upon by external organizations could reduce economic efficiency.

Appendix A: Justification of the Bureaucrat's Decision

In this appendix, we derive the properties of function $S(T, \theta)$ by considering the bureaucrat's decision of choosing S . θ is a measure of the extent of corruption or the weakness of public institutions. To simplify the derivation, we interpret θ^{-1} as a measure of the total resources available for monitoring the bureaucrat. Suppose $(\theta T)^{-1}$ units of resources are devoted to the monitoring of each unit of tax revenue. Furthermore, the probability that the bureaucrat is found stealing from any given unit of tax revenue is $\psi(S/T)(\theta T)^{-1}$, where ψ is a convex function and S/T is the proportion of each unit of tax revenue being stolen. Finally, the penalty imposed on the bureaucrat for being caught stealing from a unit of tax revenue is C . For each unit of tax revenue, the bureaucrat steals S/T , and the expected cost (penalty) of his stealing is $C\psi(S/T)(\theta T)^{-1}$. Then the bureaucrat's total expected payoff is

$$T[S/T - C\psi(S/T)(\theta T)^{-1}] = S - TC\psi(S/T)(\theta T)^{-1}.$$

Suppose the bureaucrat chooses S to maximize the above expression. Then his optimal choice of S is given by the first-order condition

$$1 - C\psi'(S/T)(\theta T)^{-1} = 0.$$

Consequently, the optimal S is

$$S = T\tau(\theta TC^{-1}),$$

where τ is the inverse function of ψ' and is increasing. The derivative of S with respect to θ is

$$S_\theta = T\tau'(\theta TC^{-1})TC^{-1} > 0.$$

The derivative of S with respect to T is

$$S_T = \tau + T\tau'\theta C^{-1} > 0.$$

Differentiate the above expression and rearrange. Then,

$$S_{TT} = \theta C^{-1}\tau'(z)[2 + z\tau''(z)/\tau'(z)],$$

where $z = \theta TC^{-1}$. Suppose function τ satisfies the condition that

$$2 + z\tau''(z)/\tau'(z) > 0, \tag{4}$$

which holds for $\tau(z) = A(z+b)^\beta + C_1$ and for $\tau(z) = Ae^{Bz} + C_2$, for any A, B, b, C_1, C_2 , and $\beta > 0$. Then, $S_{TT} > 0$, i.e., S is convex in T . Similarly, we can prove that $S_{T\theta} > 0$ under condition (4).

Appendix B: Proofs of Propositions 1 and 2

Proof of Proposition 1

Differentiate equation (1) in Lemma 1 with respect to θ . Then

$$S_{TT}T_{\theta} + S_{T\theta} = 0,$$

which implies

$$T_{\theta} = -S_{T\theta}/S_{TT} < 0.$$

Differentiate equation (2) in Lemma 1 with respect to θ . Then

$$T_{\theta} - S_T T_{\theta} - S_{\theta} + \phi\rho(Y_0 - T)k_{\theta} - \phi\rho k T_{\theta} = 0,$$

or

$$\phi\rho(Y_0 - T)k_{\theta} = S_{\theta} - T_{\theta}(1 - S_T - \phi\rho k). \quad (3)$$

By equation (1),

$$1 - S_T - \phi\rho k = \phi(r^* - \rho k) = \phi R_d > 0.$$

Since $S_{\theta} > 0$ and $T_{\theta} < 0$, (3) implies

$$k_{\theta} > 0.$$

Q.E.D

Proof of Proposition 2

(i) From equation (1), T is independent of ρ . Then, equation (2) implies that ρk is independent of ρ , which in turn implies that k decreases with ρ .

(ii) Differentiating equation (1) with respect to ϕ yields

$$T_{\phi} = -r^*/S_{TT} < 0.$$

Differentiating equation (2) with respect to ϕ and rearranging yield

$$\phi\rho(Y_0 - T)k_{\phi} = -\rho k(Y_0 - T) - T_{\phi}(1 - S_T - \phi\rho k) - \{[(f')^{-1}]'(\delta/\gamma\phi)\}(\delta/\gamma\phi^2).$$

On the right-hand side, the first term is negative, the second term is positive as $T_{\phi} < 0$ and by the proof of Proposition 1, and the third term is also positive because f' is a decreasing function. Therefore, the sign of k_{ϕ} whether the first term dominates, or is dominated by, the other two terms.

(iii) By equation (1), T is independent of γ and δ . The right-hand side of equation (2) increases with γ and decreases with δ as f' is a decreasing function. Therefore, k increases with γ and decreases with δ .

(iv) Both equations (1) and (2) are independent of ρ_f and σ^2 . Therefore, the optimal T and k are both independent of ρ_f and σ^2 . Q.E.D.

Appendix C: Alternative Assumption on the Implicit Revenue from Financial Repression

In this appendix, we consider the alternative assumption that the implicit tax revenue from financial repression is $\phi\rho k(1-\alpha)(Y_0-T)$. With this assumption, the amount of the government's usable fiscal resources is

$$Z = [T - S(T, \theta)] + [\phi\rho k(1-\alpha)(Y_0-T)].$$

The private investor's choice of α is not affected by this alternative assumption and is still α^* . Given

$$\alpha = \alpha^* = \rho\theta / [\delta k \sigma^2 (Y_0 - T)],$$

we have

$$k\alpha^*(Y_0 - T) = \rho\theta / (\delta\sigma^2)$$

and then

$$Z = T - S(T, \theta) + \phi\rho k(Y_0 - T) - \phi\rho\theta / (\delta\sigma^2),$$

which differs from the value of Z under the original assumption about the implicit tax revenue only by a constant term $-\phi\rho\theta / (\delta\sigma^2)$. Similar to the proof of Lemma 1, we can show that

Lemma 1': *The optimal T is determined by*

$$S_T(T, \theta) = 1 - \phi r^* \tag{1'}$$

and the optimal k is determined by

$$T - S(T, \theta) + \phi\rho k(Y_0 - T) = (f')^{-1}[\delta / (\gamma\phi)] + \phi\rho\theta / (\delta\sigma^2). \tag{2'}$$

Comparative Statics:

Proposition 1 is about comparative statics with respect to θ . Lemma 1' and Lemma 1 differ only by the term $\phi\rho\theta / (\delta\sigma^2)$, which is independent of θ . Therefore, Proposition 1 continues to hold under the alternative assumption about the implicit tax revenue.

Parts (i), (ii), and (iii) of Proposition 2 remain the same. However, the result about k in part (iv) changes with the alternative assumption about the implicit tax revenue;

previously, the optimal k was independent of ρ_f and σ^2 , but under the alternative assumption, the optimal k increases with ρ_f and decreases with σ^2 . Specifically, we have

Proposition 2': (i) The optimal tax T is independent of the degree of risk aversion ρ but the optimal capital control k decreases with ρ . (ii) The optimal tax T decreases with ϕ but the relationship between the optimal k and ϕ is ambiguous. (iii) The optimal T is independent of γ and δ , but the optimal k increases with γ and decreases with δ , where γ is the importance of the public good in the representative private investor's utility while δ is that of private consumption. (iv) The optimal T is independent of ρ_f and σ^2 . The optimal k increases with ρ_f and decreases with σ^2 .

The proof of Proposition 2' is similar to that of Proposition 2, except that for (i) is different. By equation (1'), T is still independent of ρ . By equation (2'),

$$\phi\rho[k(Y_0 - T) - \rho_f/(\delta\sigma^2)] = Z^* - T + S(T, \theta).$$

On the left-hand side,

$$k(Y_0 - T) - \rho_f/(\delta\sigma^2) = k(1 - \alpha^*)(Y_0 - T) > 0.$$

Therefore, $Z^* - T + S(T, \theta)$ is also positive. Furthermore, $Z^* - T + S(T, \theta)$ is independent of ρ . Then,

$$k(Y_0 - T) - \rho_f/(\delta\sigma^2) = [Z^* - T + S(T, \theta)]/\phi\rho$$

decreases with ρ , which implies that k decreases with ρ .

The intuition for Proposition 2' is the same as that for Proposition 2, except that for part (iv) of the propositions. Under the alternative assumption about the implicit tax revenue, a higher ρ_f (premium of capital flight) or a lower σ^2 (risk of capital flight) reduces the amount of domestic capital that the government can implicitly tax through financial repression. In order to maintain the level of this source of revenue, the government has to increase the degree of financial repression, which is positively related to capital control. Therefore, the government responds to a higher ρ_f or a lower σ^2 by choosing a higher k .

Appendix D: Data Documentation

1. We used two measures of **Capital Control**. The first one is based on the presence or absence of restrictions on foreign exchange transactions in five categories defined in the IMF's **Annual Report on Exchange Arrangements and Exchange Restrictions (AREAER)**, various issues. Courtesy of Milesi-Ferretti for data on the last three of the five categories.

Multiple Exchange Rates: mulex

Source: Exchange arrangements and exchange restrictions annual report 1997/1998, IMF.
Dual or multiple exchange rates.

Assign 1 if the specified practice is a feature of the exchange system, 0 otherwise.
If missing replaced with 1995/96 data.

Payment Arrears or Bilateral Payment Arrangement: payarr & bipay

Source: Exchange arrangements and exchange restrictions annual report 1997/1998, IMF.
Arrangements for payments and receipts: payment arrears or bilateral payment arrangements.

Assign 1 if any of the specified practice is present, 0 otherwise.
If missing replaced with 1995/96 data.

Controls on Payments for Invisible Transactions and Current Transfers: rescur

Source: Exchange arrangements and exchange restrictions annual report 1997/1998, IMF.
Control on payments for invisible transactions and current transfers

Assign 1 if the specified practice is present for either items, 0 otherwise. If missing replaced with 1995/96 data.

Controls on Proceeds from Exports and/or Invisible Transactions: resexp

Source: Exchange arrangements and exchange restrictions annual report 1997/1998, IMF.
Proceeds from exports and/or invisible transactions.

2 items: repatriation requirements, surrender requirements

Assign 1 if the specified practice is a feature of the exchange system for either items, 0 otherwise.

- Among the two items, if one is missing and the other one is 1, assign 1.
- Among the two items, if one is missing and the other is 0, assign 0, countries include: Antigua and Barbuda

Controls on Capital Account Transactions: cap

Source: Exchange arrangements and exchange restrictions annual report 1997/1998, IMF.
Controls on capital transactions:

1997 has Controls on 11 items, 1996 has only the first 10 items.

1. Capital market securities
2. Money market instruments
3. Collective investment securities
4. Derivatives and other instruments
5. Commercial credits

6. Financial credits
7. Guarantees, sureties, and financial backup facilities
8. Direct investment
9. Liquidation of direct investment
10. Real estate transactions
11. Personal capital movements

1997 data: Assign 1 for each item if the sum of the features > 3, 0 otherwise. Treat as missing if there are > 4 missing categories.

If there are ≤ 3 missing categories, we assign the most common ratings in the rest of the categories to replace the missing values. These countries are: Algeria, Angola, Barbados, Belize, Bhutan, Bosnia and Herzegovina, Botswana, Burundi, Cameroon, Central African Republic, Chad, Columbia, Comoros, Congo, Rep. of, Costa Rica, Dominica, Equatorial Guinea, Gabon, Gambia, Georgia, Grenada, Honduras, Jamaica, Latvia, Lesotho, Liberia, Libya, Lithuania, Maldives, Mali, Mauritania, Mongolia, Oman, Papua New Guinea, Qatar, Romania, Russia, Sit. Kitts and Nevis, St. Lucia, St. Vincent and the Grenadines, Saudi Arabia, Senegal, Seychelles, Somalia, Sudan, Syrian, Turkmenistan, Uzbekistan, Zimbabwe

1996 data: Only look at the first 10 items: Assign 1 for each item if the sum of features > 3, 0 otherwise. Treat as missing if there are > 4 missing values.

1995 and before:

Used the data on Southern Yemen (data closer to later data) for Yemen Rep.
Used the data on Belgium-Luxembourg for both Belgium and Luxembourg.

1991 and before:

Used the data on Czechoslovakia for Czech and Slovakia:
Used the data on former Yugoslavia for Yugoslavia, FDR;

Before 1989: Used the data on West Germany for Germany.

Second measure of Capital Control is more detailed coding of restrictions on close to 50 items of capital account transactions (together with a similarly detailed coding of current account restrictions), computed by Natalia Tamirisa for Tamirisa (1999) and Johnston and etc. (1999), based on the IMF's **Annual Report on Exchange Arrangements and Exchange Restrictions (AREAER)**, 1997. Courtesy of Natalia Tamirisa.

2. Measures of Corruption

ICRG Index

Corruption in Government from the International Country Risk Guide.

Bahamas, Malta, Mongolia, Yugoslavia, FR (Serb./Mont.): use the data from 1986 for 1985; Bahamas, Burkina Faso, Congo, Rep., Gambia, The, Guinea-Bissau, Korea, Dem. Rep., Malta, Mongolia, Niger, Sierra Leone, Yemen, Rep., Yugoslavia,

FR(Serb./Mont.), used the data from 1985/86 for 1984. Original scale 0-6, Lower point totals indicate higher risk, rescale as $6 - \text{original score}$.

TI Index

Source: Transparency International (<http://www.gwdg.de/~uwvw/icr.htm>), used 1998 index, which will be the ranking for 1997.

CPI has adopted the approach of a composite index. It is a "poll of polls". It consists of credible surveys using different sampling frames and varying methodologies. The 1998 CPI includes data from the Economist Intelligence Unit (Country Risk Service and Country Forecasts), Gallup International (50th Anniversary Survey), the Institute for Management Development (World Competitiveness Yearbook), the Political & Economic Risk Consultancy (Asian Intelligence Issue), the Political Risk Services (International Country Risk Guide), World Development Report (Private Sector Survey) and the World Economic Forum (Global Competitiveness Report), etc.. Note: TI has corruption indexes for earlier years as well. However, the underlying methodology changes every year which makes inter-year comparison misleading. We re-scaled the TI index by subtracting the original numbers from 10 so that a large number implies more corruption.

GCR Index

Source: Appendix to Kaufmann and Wei, "Does 'Grease Money' speed up the wheels of commerce". NBER working paper 7093. Original source: Global competitiveness report 96, 97

GCR are surveys conducted by the World Economic Forum and Harvard Institute for International Development for the 1996 and 1997 Global Competitiveness Reports, respectively. GCR surveys are on 1-7 scales. Corruption rating for a country in this table is the average of all individual responses for that country. In original surveys, a low number means more corruption, the rating is re-scaled as $8 - \text{original rating}$. GCR97 is published in 1997 and the ranking is for 1996.

WDR Index

Source: Appendix to Kaufmann and Wei, "Does 'Grease Money' speed up the wheels of commerce" NBER working paper 7093. Original source: 1997 World Development Report, survey conducted by the World Bank for its 1997 World Development Report. The rating is then for 1996.

WDR surveys are on 1-6 scales. Corruption rating for a country in this table is the average of all individual responses for that country. In original surveys, a low number means more corruption, the rating is re-scaled as $7 - \text{original rating}$.

3. Instrumental Variables for Corruption

Civil liberty and political freedom (1993)

Source: Freedom House, Freedom in the World, Freedom House Survey Team, 1993-1994

CIV is the abbreviation for civil liberties index. Liberties index measures the extent to which people are able to express their opinion openly without fears of reprisals

and are protected in doing so by an independent judiciary. Though this index reflects rights to organize and demonstrate as well as freedom of religion, education, travel and other personal rights; more weight was given to those liberties most directly related to the expression of political rights. This variable is an index and not in logs.

POL is the abbreviation for political right index. Political rights index measures rights to participate meaningfully in the political process on a scale of one to seven where lower numbers indicate greater political rights (see Gastil, 1989). A high-ranking country must have a fully operating electoral procedure, usually including a significant opposition vote. It is likely to have had a recent change of government from one party to another, an absence of foreign domination, decentralized political power and a consensus that allows all segments of the population some power. The index was constructed on the basis of satisfaction of the above and other related criteria by the countries in question. This variable is an index and not in logs.

Both indexes range from 1 to 7. Smaller number means higher degree of freedom. Democracy is defined as $(7-civ)+(7-pol)$.

Corruption in Judicial System

Source, "lack of legal corruption," survey in 1996 for the Global Competitiveness Report 1997.

Question 8.09 Legal corruption, "Irregular payments to judges or other officials involved in the enforcement and execution of judgements are not common and do not influence the outcome of court proceedings" (1=strongly disagree, 7=strongly agree).

Rescaled $7 - \text{original score}$ Thus a smaller number means less corrupt judicial system.

4. Tax Evasion and Tax Rates

Tax Evasion

Source: survey (in 1996) for the Global Competitiveness Report 1997

2.10 Tax evasion, Tax evasion is minimal in your country. (1=strongly disagree, 7=strongly agree). Re-scaled as $7 - \text{original score}$

Statutory Corporate Tax Rates

Courtesy of Altshuler for providing the data used in Altshuler, Grubert and Newlon (1998)

Notes: 1. For Bermuda, effective tax rate was used instead of statutory rates. The statutory rate for Bermuda was zero, but the effective rate was positive. 2. In some cases judgement was made on the appropriate rate due to the presence of tax holidays.

5. Other Variables

Current Account Surplus

Source: World Bank Sima/GDF & DDI Central

Current account balance (% of GDP)1984-1997, in cross section regression used the average of 1984-96.

Government Consumption

Source: World Bank Sima/GDF & WDI Central

General government consumption (% of GDP)

1984-1997, in cross section regression used the average of 1984-96.

Government Debt

Source: World Bank Sima/GDF & WDI Central

Central government debt, total (% of GDP)

1984-1997, in cross section regression used the average of 1984-96.

Inflation

Source: World Bank Sima/GDF & WDI Central

Inflation, consumer prices (annual %) Inflation as measured by the consumer price index reflects the annual percentage change in the cost to the average consumer of acquiring a fixed basket of goods and services. In general, a Laspeyres index formula is used.

1984-1997, in cross section regression used the average of 1984-96.

Index of Legal Independence of Central Banks

Source: Courtesy of Milesi-Ferretti. Original source is Cukierman et al. (1992).

1984-89, used 1989 data in cross section regressions

Higher numbers correspond to more central bank independence.

Actual Turnover of Central Bankers Per Year.

Source: Courtesy of Milesi-Ferretti. Original source is Cukierman et al. (1992).

1984-89, used 1989 data in cross section regressions

1. White-robust standard errors in brackets. **, * and # denote significant at the 5%, 10% and the 15% levels, respectively.

2. Pseudo R² for ordered probit and IV regressions. Adjusted R² for panel regression (LSDV, fixed effects with year dummies).

3. Estimates on the constant and the cutoff parameters are not reported.

Table 5: Effect of a Rise in Corruption on Capital Controls <cite in the text>

	<i>P0</i>	<i>P1</i>	<i>P2</i>	<i>P3</i>	<i>P4</i>	<i>P5</i>
(Based on the last regression in Table 3)						
Corruption = 4.3 (e.g. Ukraine)	0.13	0.26	0.15	0.31	0.10	0.04
Corruption = 1.6 (e.g. Singapore)	0.64	0.25	0.06	0.05	0.01	0.00
(Based on the second to the last regression in Table 4)						
Corruption = 4.3 (e.g. Ukraine)	0.04	0.28	0.34	0.33	0.01	0.00
Corruption = 1.6 (e.g. Singapore)	0.68	0.28	0.04	0.00	0.00	0.00

Note: *P0*, *P1*, ..., *P5* denote the probability that the aggregate capital control index = 0, 1, ..., 5, respectively. Used average values for explanatory variables other than corruption.
