SOEPPapers on Multidisciplinary Panel Data Research at DIW Berlin

This series presents research findings based either directly on data from the German Socio-Economic Panel Study (SOEP) or using SOEP data as part of an internationally comparable data set (e.g. CNEF, ECHP, LIS, LWS, CHER/PACO). SOEP is a truly multidisciplinary household panel study covering a wide range of social and behavioral sciences: economics, sociology, psychology, survey methodology, econometrics and applied statistics, educational science, political science, public health, behavioral genetics, demography, geography, and sport science.

The decision to publish a submission in SOEPPapers is made by a board of editors chosen by the DIW Berlin to represent the wide range of disciplines covered by SOEP. There is no external referee process and papers are either accepted or rejected without revision. Papers appear in this series as works in progress and may also appear elsewhere. They often represent preliminary studies and are circulated to encourage discussion. Citation of such a paper should account for its provisional character. A revised version may be requested from the author directly.

Any opinions expressed in this series are those of the author(s) and not those of DIW Berlin. Research disseminated by DIW Berlin may include views on public policy issues, but the institute itself takes no institutional policy positions.

The SOEPPapers are available at

Gender, Migration, Remittances:

Evidence from Germany

by Elke Holst*

Andrea Schäfer**

and Mechthild Schrooten***

Abstract

Gender-specific determinants of remittances are the subject of this study based on German SOEP data (2001-2006). In 2007, about 7.3 million foreigners were living in Germany. While the total number of foreigners has decreased over the last decade, female migration to Germany has increased. A feminization of migration is observable all over the world, and is changing gender roles in the households of origin as well. Today, women constitute 48.6% of migratory flows to Germany, although the proportion varies significantly by country of origin. A feminization of migration is observable all over the world, and is changing gender roles in the households of origin as well.

To date, research has failed to address the gender-specific determinants of remittances from Germany. Here we attempt to fill this gap, focusing on gender roles and network effects. We distinguish between three different groups of migrants: foreigners, Germans with migration background, and all individuals with personal migration experience. Our main findings show, above all, that gender matters. However, the gender differences identified disappear after controlling for transnational (family) networks. Taking interaction terms into account reveals gender-specific network effects. In addition, different groups of migrants show remarkable differences in international networking. We find that female foreigners, but not female migrants with German citizenship, remit less than males if their children live abroad as well. Female migrants with German citizenship send more money home if their siblings remain in the home country. We find the reverse in the case of female migrants with foreign citizenship.

Our findings show that female migrants tend to support their children first and foremost, while male migrants tend to support a wider network of more distant family members and friends. This finding is in sharp contrast to previous studies on remittances. It makes clear that there is little evidence supporting the assumption that remittances simply follow income-difference based altruism or that women are more altruistic than men. Furthermore, there seems to be evidence that the gender-specific differences detected in remittance behavior might be due to gender-specific migration patterns and the relative role of the migrant within the transnational network. 1 Introduction

In 2007, about 7.3 million foreigners were living in Germany. While the total number of foreigners has decreased over the last decade, female migration to Germany has increased. Today, women make up 48.6% of the migratory flows to Germany, though the proportion varies significantly by country of origin (Federal Statistical Office 2008). A feminization of migration is observable all over the world and is changing gender roles in the households of origin as well (Ramirez 2005). Of course, both male and female migrants send money home. From a global perspective, these remittances are considered the driving force behind migration and indicate the existence of transnational private networks and transnational family life (Guarnizo 2003; The World Bank 2005). Worldwide remittances are increasing. In 2007, remittances from Germany amounted to more than twelve billion US dollars, making Germany one of the top five source countries for this kind of cross-border transfers (The World Bank 2008).

From a theoretical perspective, remittances are usually analyzed from the angle of international labor economics and in the context of the economics of migration. Seminal work was done by Lucas and Stark (Lucas/Stark 1985; Stark 1995), who analyze altruism-driven remittances and explained this phenomenon in the context of the new economics of labor migration (NELM). More recent models assume that migration and remittances offer the possibility for portfolio diversification and insurance against income uncertainty (Rosenzweig 1988; Poirine 1997; Foster/Rosenzweig 2001). One common prediction of all these approaches is that remittances will decline over time – a finding that is in sharp contrast to many studies based on macro-data. Furthermore, gender-specific patterns of migration have been neglected in the theoretical literature on remittances to date. This might be due partly to the focus on labor migration, in combination with the assumption that most migrant workers are men, and that women are their dependents. In redressing this analytical imbalance, several empirical studies emerged since taking gender as a central dimension of social structure and economic decision-making (Portes 1997; Pessar/Mahler 2003; Sørensen 2005; Ramirez/Dominguez/Morais 2005; Orozco/Lowell/Schneider 2006). However, the results are not clear-cut when studying different countries and different data sets.

A study that addresses the gender-specific determinants of remittances from Germany is still lacking. One common finding of the existing papers on remittances from Germany is that females remit less than males (Merkle/Zimmermann 1992; Oser 1995; Holst/Schrooten 2006; Holst/

Schaefer/Schrooten 2008). Studies analyzing remittances in the context of savings support this view (Sinning 2007). However, pooling men and women in the estimation can be justified only if the crucial explanatory variables indeed do not vary by sex.¹

Here and in contrast to earlier studies, we check this assumption empirically. In doing so, our paper fills at least three analytical gaps. First, we show that gender-specific determinants of remittances exist. Second, we analyze the importance of private networks abroad for gender-specific patterns of remittances. Third, we investigate whether different groups of migrants such as foreigners and Germans with a migration background vary in their remittance decisions. The analysis is based on data provided by the German Socio-Economic Panel (SOEP). We pooled data from the years 2001-2006.² In this survey, participants answer a broad range of questions concerning their socio-economic status, demographic characteristics, as well as integration into country of destination and family and friends networks in both host and home country. We are thus able to exploit information not only on the recent social status of the migrant in the host country but also on the existing networks in the home country.

The paper is organized as follows. Section 2 gives some insights into the determinants of remittances and networks from a theoretical point of view. In Section 3, the data set, the general estimation approach, and the variables employed are explained. The results of the econometric models are discussed in Section 4. The conclusions (Section 5) present not only policy recommendations but also potentially fruitful directions for further research.

2 Remittances: Networks, Transnationalism, and Gender – The Theoretical Background

Seminal work on remittances was done by Lucas and Stark (1985). Their basic microeconomic model relies on altruism. With altruism, the utility function of the migrant depends not only on her own consumption, but also on the utility of the relatives left behind (Lucas/Stark 1985; Stark 1995). Their utility is a function of consumption, which depends on the income either generated at home or received in the form of remittances, as well as their degree of altruism. Important

¹ Technically speaking, when controlling for sex using a dummy variable, all coefficients are assumed to be the same for men and women.

² See SOEP (2001).

implications are that transfers cannot increase with the recipient's income and will decrease over time.³

A second class of models emphasizes the family of the migrant as the important decision-making unit. Within this context, migration and remittances are considered to result from social interactions. The most important approaches take insurance or investment motives into account (see for overview Rapoport/Docquier 2005). Within this framework, the existence of an intra-family contract, either to reduce uncertainty or finance investment, is assumed. Usually the decision-making processes are analyzed within a two-member family living for two periods. For each member, the income I^1 is given in period 1, the income in period 2 is random and amounts to \underline{I}^h with probability p and \bar{I}^h with probability $(1-p)$. It is assumed that $\underline{I}^h < \bar{I}^h$. This framework allows the formulation of a function of expected utility $E(V)$, which depends not only on the income and the probability to realize a certain income but also on the degree of risk aversion v with $v' > 0, v'' < 0$

$$(3) E(V) = I^1 + p v(\underline{I}^h) + (1-p)v(\bar{I}^h).$$

It is assumed that migration reduces income uncertainty. However, migration-specific transaction costs (t) have to be covered. These costs are high and range between

$$(4) I^1 < t < 2 * I^1.$$

The existence of these costs requires financing from larger kinship networks (the “extended or transnational family”). Since these migration costs have to be shared by the potential migrant and the non-migrant, there exists a set of Pareto-efficient contracts that have to fulfill the following condition

$$(5) \text{Max } E(V^m) + \lambda [E(V^h) - V^h].$$

³ Other models focusing on the individual utility function of the migrant underscore the argument of payment for services at home (exchange) or strategic behavior. While the exchange argument is covered relatively well by the standard model – the amount of remittances increases with increasing demand for services at home – arguments based on strategic behavior require a more sophisticated approach. The general assumption that migrants compensate non-migrants for staying at home is interesting (Stark 1995; Stark/Wang 2002).

Important factors are the share of migration costs covered by the migrant and λ , the relative bargaining power of the non-migrant. In general, these kinds of models consider the family to reduce uncertainty and therefore to be a substitute for a smoothly functioning insurance and financial sector in the remitter's home country. Models relying on the investment motive argue that migration costs related to the creation of human capital and education are covered by the family through an intra-family loan (Poirine 1997). Within such framework, better educated migrants transfer more than low-skilled migrants because of their more demanding responsibilities.⁴ Models using the insurance motive point out that the risks at home and the risks in the foreign country are not correlated.⁵

These theoretical models are usually tested empirically by checking for the explanatory power of the age of the migrant, education, the length of the stay abroad, the migrant's income, and the household size in the host country.⁶ According to the theoretical models relying on insurance and investment, there is no reason for a decrease of remittances with the length of stay. In addition, better education should lead to higher remittances. Remittances out of investments and insurance are expected to be more likely and higher as the distance from the family increases.⁷ However, the theoretical approaches presented above neglect the importance of structure of the transnational (family) network. Nevertheless, there seems to be evidence that these network effects matter (Sana/Massey 2005). Within the theoretical framework presented above, migration costs play a critical role and these transaction costs have been treated as exogenous. It is known from the huge body of sociological literature that migration costs tend to decrease with the size of the relevant network of migrants in the destination country. In addition, recent approaches argue that only a small proportion of migrants settle permanently in the destination country assimilate

⁴ In practice, of course, the strength of personal ties between the remitter and the recipient also plays a major role within the altruism model, as VanWey (2004) indicates. Galor and Stark (1990) demonstrate that the positive probability of immigrants to return to their home countries positively affect remittances (see also Rapoport/Docquier 2005 for a review).

⁵ Migration and remittances are considered to be a component of intra-family allocation decisions, mainly compensating for weaknesses in the domestic social security system and financial sector.

⁶ In practice, however, it can be assumed that remittances are not driven by a single motive. Some recent theoretical models therefore combine different motives, for example, altruism and insurance (Foster/Rosenzweig 2001). Nevertheless, these models often suffer from the fact that the different motives cannot be discriminated completely. Furthermore, remittances made out of altruistic motives might induce "spillover effects", given that some services or investment opportunities are offered specifically to migrants.

⁷ The theoretical literature draws no differentiation between the probability to remit and the amount remitted.

into the new culture (Lucassen 2006; Morawska 2002). Furthermore, a great deal of migration is circular (Constant/Zimmermann 2007). Transnationalism – with respect to migration – refers from our perspective to migrants who are constantly involved in cross-border economic, socio-cultural, and political activities (Bash 1994). Thus, relations between the destination country and home country are forged and sustained to maintain ties or cope with experiences in country of destination, however differently for men and women (Itzigsohn/Giorguli-Saucedo 2005).

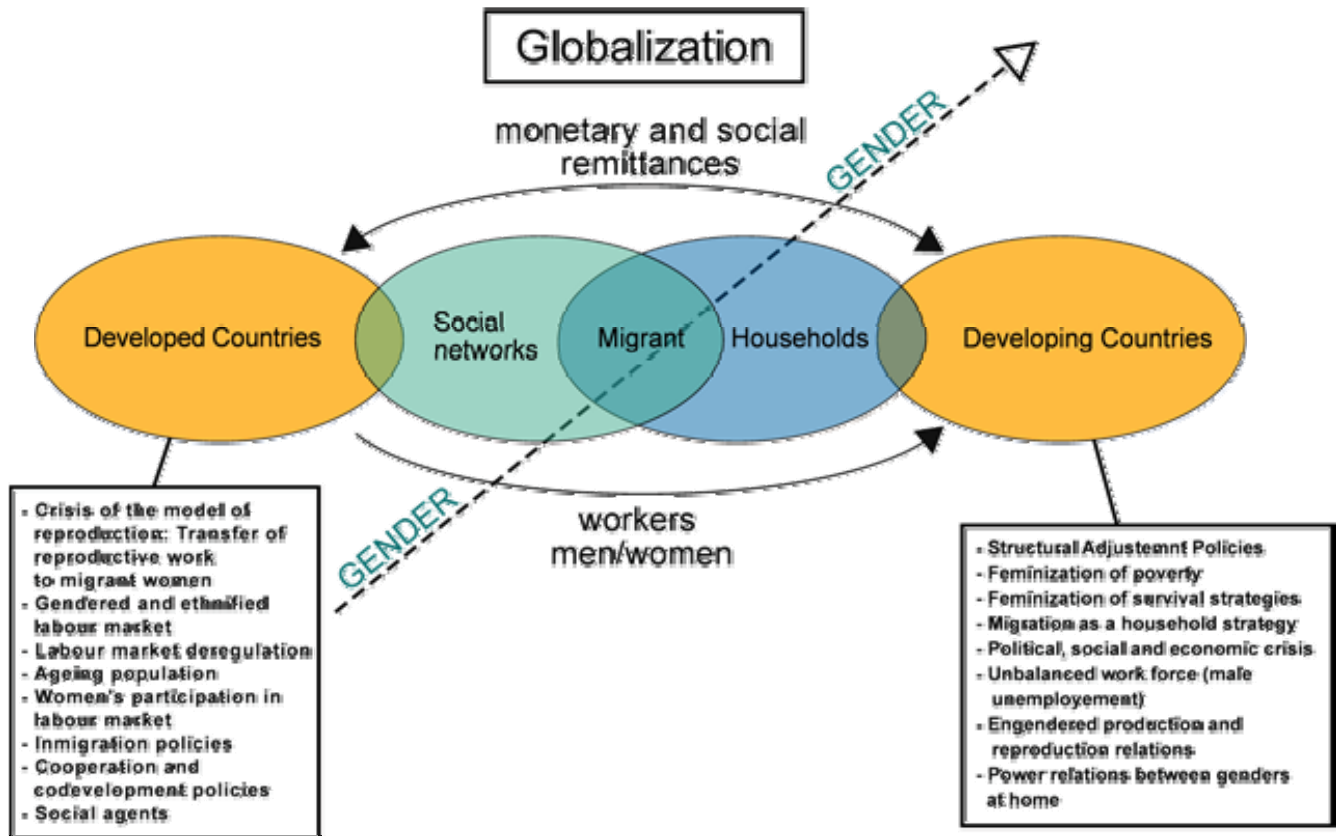

Until now the link between transnational activities – such as remittances – integration and private network relations has inspired very few theoretical works (Feist 2000; Morawska 2002). In particular, the analysis of the linkages between networks, migration, remittances, and gender roles is a fairly new branch of the research (Ramirez 2005). However, it becomes clear that migration and remittances have an important impact on economic and social life not only in the host country but also in the home country. Consequently, to analyze the determinants of remittances one must take into account the structural and personal characteristics of the migrants themselves, and their households (social interaction) in both the host and the home country (Table 1).

Table 1: Dimension of Social Integration and Determinants of Remittances

Dimension	Determinants
Social (Interaction) ... at origin	Family and Friends Network: (grand)parents, children, siblings, further relatives, friends
... at destination	Householdsize in Germany
Structural (Placement in destination country)	Marital Status
	Individual Income
	Family Income
	Education
Personal (Identification with destination country)	Remigration Plans
	Relative Duration of Stay
Source: authors' based on Esser (2001:16)	

The distribution of economic power within a family can also change with female migration. In this context it can be argued that gender is a central dimension of the structure of transnational life in the globalised world (Figure 1).

Figure 1: Gender, Networks and Remittances

Source: Ramirez (2005:23).

It starts with the fact that female migrants are increasingly considered as a part of the labor market in the host country, which is usually a highly developed economy. This labor market participation leads to changes in gender roles and affects the structure of social nets and the distribution of economic power within the family of the migrant. Again, these changes have a considerable impact on the economic life in the home country of the migrant. If migration becomes more attractive to women, the relative (economic) position of the women in the home country changes. The gender dimension enters the equation due to the fact that the relative position of the migrant might determine her responsibilities within a given family network. Nevertheless, there seems to be empirical evidence that females are comparably risk adverse (Grazier/Sloane 2006). They are willing to change money for security and stability, an argument which was already used in the early 1950s to explain wage differences between men and women (Friedman 1953). Within a given transnational family network, females were thought to support those network structures that appeared to offer a high degree of security and to reduce risks.

3 Data and Econometric Approach

The German Socio-Economic Panel Study (SOEP) provides data on private households and individuals. In our analysis, we use data from the years 2001-2006 (study time 2000 to 2005) on the individual level. In this survey, participants answer a broad range of questions concerning their socio-economic status, demographic characteristics as well as on their integration into German society. In addition, they provide information on family and friend networks in both the host and the home country. For those born outside of Germany and those without German citizenship, we obtain valid information on their network outside of Germany (relatives in the home country) with the question “*Do you have close relatives who do not live in Germany?*”. In our estimation, this information is captured in dummy variables stating whether or not one has relatives of an older generation (parents/grandparents), younger generation (children), the same generation (siblings), or other relatives or non-relatives living abroad.

In our case, the dependent variable is the natural log of the annual “amount of remittances”. Remittances are measured and for data from 2001 converted in euro.⁸ Since we focus on the determinants of the amount of remittances, which are defined as individual cross-border transfers by foreigners or migrants, the retrospective question in the SOEP questionnaire is crucial: “*Have you personally provided payments or support during the last year (2001) to relatives or other persons **outside** of your household? How much in the year as a whole? Where does the recipient live? Germany – Abroad?*”⁹ All participants have to state whether they transferred money to their (step)parents, (step)children, (ex)spouse, or other relatives or non-relatives. In case of non-payment, they could check the box: “*No, I have not given any payment or support*”. We thus obtain individual information, not only on the frequency of transfers to certain people but also on the amount transferred.

Cross-border transfers to relatives and friends living in the home country are not only made by foreigners: many Germans with personal migration experience send money back to their country of origin as well. Fortunately, the structure of the SOEP data set enables us to differentiate between foreigners and naturalized migrants (Holst/Schrooten 2006).¹⁰ Therefore we distinguish

⁸ The exchange rate for one Euro was 1.95585 DM.

⁹ For details see: <http://www.diw.de/deutsch/sop/service>.

¹⁰ However, we do not take into consideration migration within Germany (from East to West or opposite) and do not consider the migration status of other household members (household migration context)

between the broader group of migrants, i.e., people with a personal migration experience and Germans with migration background, the narrower group of Germans with migration background and foreigners (Figure 2).

Figure 2: Migrants, Foreigners and Germans with Migration Background

Source: authors'.

We expect that foreigners and German migrants have different remittance patterns due to their different integration and status in Germany. Analyzing solely the remittance behavior of the broad group of migrants would not enable us to disentangle these effects. Table 2 provides some basic information about the average remittances sent.

Table 2: The Amount of Remittances in Euro (annually), 2001-2006

	Migrants		Foreigners					
	Women	Men	Women	Men	Women	Men	Women	Men
Year	Mean	Median	Mean	Median	Mean	Median	Mean	Median
2001	1 066	767	1 456	1 022	1 247	1 022	1 565	1 022
2002	1 340	675	1 631	1 000	1 656	1 000	2 127	1 000
2003	1 469	800	1 612	1 000	1 750	1 000	1 866	1 200

Note: persons older than 18 years living in private households; weighted mean

Source: 2001-2006 SOEP, authors' calculations

All in all, the average amount of remittances increased over time. This finding is totally in line with macro data on remittances. The highest growth was reached in the group of male foreigners. In 2006, the average amount remitted by this group was as twice as high as in 2001 and accounted for more than 3 200 euros. In general, foreigners remit more than migrants, which might be due to the higher pressure on them for return migration. This finding holds true for both women and men. In addition, gender-specific patterns are observable. In both groups, foreigners and migrants, women remit less than men. In 2006, the average amount remitted by foreign women accounted for only 50 percent of the average amount remitted by foreign men.

To explain the determinants of the amount remitted, several standard explanatory variables are employed:

Age: According to the theoretical literature, the age of the remitter plays a positive role. However, beyond a certain age, this tends to decline. This finding is reported in many empirical studies and often explained by the assumption that personal ties in the recipient countries become more distant with age. The variable “age squared” is used to control for these non-linearities. In accordance with the existing literature, we expect a positive sign of the variable age and a negative one in the case of the variable age squared.

Gender: Many empirical studies report a significant influence of gender on the amount of remittances. While Lucas and Stark (1985) found in their seminal work on remittances that women show a higher probability to remit, more recent studies have produced the opposite finding. Here we use a dummy variable to check for the gender effect. The variable “gender” is 1 in the case of a female remitter and 0 in the case of a male remitter.

Marital status: Several empirical studies come to the conclusion that married migrants send larger amounts of remittances abroad (Merkle/Zimmermann 1992; Sinning 2007). Therefore we expect a positive sign of this dummy variable.

Education: The value of the migrant’s human capital is reflected in years of education. According to theoretical models that rely on altruism as well as on intra-family-investment schemes, better education leads to higher transfers. Therefore a positive sign is expected here.

Income: To capture the influence of the migrant’s income, we use monthly individual income data. In addition, we construct the net equivalent family income in subtracting the individual income from the household income, which should capture the income of other family members

and make it easier to compare persons in households with different numbers of members. According to the theoretical literature, remittances increase with the migrant's per capita income. This finding is reported in all microeconomic models. Therefore, we expect this variable to show a positive sign for the personal labor income of the migrant and foreigner.

Household size in Germany: One important determinant of the amount of remittances is the household size of the migrant in the host country. The more members of the household live in Germany, the more Germany can be considered the locus of family life. Therefore, and in line with the theoretical models and empirical findings, we assume that the amount of remittances decrease with increasing numbers of members in the migrant's household in Germany.

Relative duration of stay: The variable "relative duration of stay" is constructed as "years in Germany divided by age" and reflects the influence of the years spent in Germany on remittances. The variable ranges between 0 and 1 and takes the value of 1 if the migrant has spent his or her entire lifetime in Germany. This variable can be taken as a proxy for the influence of the duration of the stay in Germany (relative to the age of the migrant). According to the construction of the variable, we expect a negative sign, which is in line with the findings from several previous empirical studies showing that remittances decrease with the length of the stay abroad.

Remigration plans: In addition, the migrant's plan for return migration may influence the decision on remittances. Fortunately the SOEP data enable us to check for this. We assume that personal remigration plans are strongly linked to social networks abroad. Remittances are one important tie between the social network in the home country and the migrant. Therefore we expect a positive sign in the case of future return migration plans.

Social networks: In addition to these standard variables, we check for the existence of social networks in the home country. To analyze the network effects, we construct dummy variables for having (grand)parents, children, siblings, or other relatives or friends abroad. In line with the literature on remittances, we assume that in general the existence of social networks abroad will lead to higher remittances. Therefore we expect positive signs of all the network variables employed.

After excluding all observations with missing values on one of the variables used in the analysis, the panel data set contains 10 440 observations in the case of migrants and 6 627 observations in the case of foreigners (2001-2006). Because not all immigrants remit, the data set contains many

zeros. To deal with this issue, in analyzing the determinants of the amount of remittances we perform estimations of Tobit models, which enable us to analyze the determinants of the positive amount in relation to socio-economic variables. For all panel models, Hausman statistics were calculated to test the choice between random or fixed effects models. Although random effects models do not control for omitted characteristics of the individuals, our objective was to include stable covariates such as family network of the individual.

4 Empirical Results

The fact, that one person remits can be interpreted as an indicator of the existence of personal ties to the home country. As the descriptive statistic shows, about one-fifth of the migrants living in Germany send money home. What determines the amount of remittances? Here, we proceed in three steps. All the models are estimated separately for the broad group of migrants, for Germans with a migration background, and for foreigners (Tables 3, 4, 5). First, we estimate the “core” equation, which answers the question of how important the standard variables are in general. In doing, so we check for the importance of the variable “gender” (Model a). Second, since we want to attain further insights into network effects and gender-specific differences in remittances, we estimate an extended equation (Model b). In addition, we estimate Model b separately for males and females (Model c). Third, and foremost we introduce interaction terms and check for their explanatory power (Table 6).

4.1 The Core Model

Tables 3, 4, 5 present the results of the “core” model in all three cases: migrants, foreigners, and Germans with migration background (Column 1). Focusing on the broad group of migrants, our central findings are: female migrants remit significantly less than males. Remittances increase with the age of the migrant. However, this relationship is not linear. This is in accordance to the finding that with the duration of the stay, the amount remitted decreases significantly. Being married and plans for remigration lead to significantly higher remittances. The same holds true for higher personal income. Nevertheless, no significant influence of net household equivalent income on remittances is reported. In addition, better education leads to significantly higher remittances. All in all, the results reported support the view that remittances can be at least partly

considered as a tool for international insurance and risk diversification. This is totally in line with the existing literature on remittances from Germany (Merkle/Zimmermann 1995; Oser 1995; Sinning 2007).

Turning now to the subgroups of foreigners and Germans with a migration background, we find several differences in remittance behavior. While female foreigners remit significantly less than males, the variable “gender” has become insignificant in the case of Germans with a migration background. In addition, the household size in Germany has no significant effect on remittances of Germans with a migration background. In the case of foreigners, it becomes clear that there is no significant linkage between the level of education and the amount remitted.

4.2 Network effects

Now we check for the explanatory power of transnational (family) networks. Model b clearly reveals that networks are important for all three groups. However the effects of the different network variables on remittances vary widely between the three groups. Focusing on migrants, it becomes clear that having children, siblings, and friends abroad has a positive impact on the amount remitted (Table 3). Nevertheless, intergenerational transfers seem to go first and foremost to the younger generation. It appears noteworthy that after controlling for network effects, the gender variable becomes insignificant, indicating that the remittance decisions of men and women follow a similar structure. In addition, remigration plans are no longer significantly related to remittances. At first glance, there is little reason to assume that the gender-pooled estimation leads to misleading results. However, turning to Model c, which enables us to distinguish between the groups of women and men, we see that gender-specific differences in remittances do exist. Men and women send more money home if parents, grandparents, or children live abroad. Having friends living abroad indicates higher remittances only in the case of men. In contrast to earlier studies using a specific data set (Orozco/Lowell/Schneider 2006), there seems to be evidence that women’s remittances are concentrated on intergenerational transfers. In other words, men seem to have a wider network than women.

Similar patterns can be detected in the case of foreigners (Table 4). Again, after checking for network effects, the variable gender becomes insignificant. However, within the set of variables on social networks only the variable “children abroad” shows a significantly positive impact on remittances. Model c reveals that women and men differ concerning their remittance behavior.

While, men also seem to feel responsible for siblings and children abroad, women focus their remittances on children.

Turning now to the group of Germans with a migration background (Table 5, Model b) it can be shown that having parents/grandparents, siblings or friends abroad leads to higher remittances. Focusing on the gender-specific aspects of remittances (Model c), it becomes clear that females remit more if parents/grandparents, siblings, or friends are living in the home country. In the case of men, significantly higher remittances are reported if parents/grandparents, children, or friends are living abroad. All in all, remittances seem to depend on the relative position of the migrant within the transnational family.

4.3 What determines the gender-specific pattern of remittances?

Do our findings for the two separated groups of women and men also mean that the amount remitted depends significantly on gender-specific patterns? To check for significant differences, we use interaction terms (Table 6). For the broad group of migrants, we see that if parents/grandparents or children are living abroad, females remit less than males. Only by looking at the two subgroups of foreigners and Germans with a migration background we can identify different social network effects on the amount of remittances. First we see for foreigners with remigration plans that women remit less than men, an effect that is not significant for the group of German migrants. Second, in the case of foreigners with children abroad, women remit significantly less than men. This effect is also not significant in the group of Germans with a migration background. Third, in the group of foreigners with siblings abroad, women remit less than men. Here we find that just the opposite is true for Germans with a migration background: women remit even more than men. In the estimation for the broad group of migrants, this effect was not significant because the effects of the subgroups canceled each other out. All in all, these findings indicate that the relative position of the migrant within the transnational family seems to play an important role for remittances.

Table 3: Migrants, dependent variable: annual amount of remittances¹

	Core Model	Network Model	Network Model

5 Conclusions

The results presented show that gender-specific patterns of remittances exist. In addition, the study underlines the hypothesis that one important motivation of remittances might be the existence of transnational (family) networks. We have shown that female migrants tend to send support to their children first and foremost, while male migrants tend to support a wider network of more distant family members and friends. This finding is in sharp contrast to previous studies on remittances. It makes clear that there is little room for the assumption that remittances simply follow income-difference-based altruism or that women are more altruistic than men.

The gender-specific differences in remittance behavior identified here might be due to gender-specific migration patterns. However, they also might be due to the relative position of the migrant within the transnational network: in other words, whether or not the migrant is considered the major breadwinner for a broader range of family members living abroad.

This study can be considered a first step in the analysis of remittances from the perspective of gender economics. The analysis of linkages between the structure of transnational networks and gender-specific remittance behavior also shows a potentially interesting direction for future research. One natural extension of this paper would be a deeper investigation of the social determinants of remittances, possibly linking the social networks literature to the economic literature on remittances. Such a study should analyze how the quality of the transnational network influences the decision to remit. In addition, deeper investigation of the potential gender-specific motivations of migrants might be possible using the tools of experimental economics (Fehr/Fischbacher/Rosenblatt/Schupp/Wagner 2002).
