Executive Summary

Overview

Childcare is often viewed as one of the biggest barriers to work, particularly among lone parents. All children in England are eligible to start part-time nursery education from the beginning of the academic term after they turn three, and most are eligible to start full-time primary education on 1 September following their fourth birthday. Both policies effectively provide parents with a number of hours of free childcare. Moreover, these rules mean that some children born only one day apart are eligible to start nursery up to four months apart and school up to one year apart. This report exploits these discontinuities to investigate the *causal* impact of a lone parent's youngest child being eligible for part-time nursery education or full-time primary education on welfare (benefit) receipt and employment outcomes.

The method used is called the regression discontinuity (RD) approach. This boils down to comparing the outcomes of lone parents whose youngest child is born just before a cut-off date (1 September, for example) with those born on or just after that date. The attraction of doing this is that the two groups of lone parents should be very similar to each other, except that the youngest child of one group of lone parents is eligible for nursery or school; this is similar to what would be achieved in a randomised experiment.

The report makes use of rich administrative data (the Work and Pensions Longitudinal Study) which records children's exact date of birth and home postcode (used to identify the admissions policy in each lone parent's local authority). It improves on previous studies by estimating the precise timing (relative to the date on which part-time nursery or full-time primary education begins) of any impact on labour supply, allowing an assessment of whether there are anticipation or experience effects. Moreover, it focuses on a group which previous studies have suggested are particularly responsive to this type of incentive.

Key findings, and lessons for policy

Having a youngest child who is entitled to full-time primary education (rather than part-time nursery education) increases the proportion of lone parents on Income Support who leave welfare

by a small, but significant, margin of around 2 percentage points, or 10 per cent. The impact on those who move into work is very similar. These effects do not start to emerge until some four to six months after entitlement to school begins, which suggests that lone parents may not start looking for work until this point. The impact peaks around eight to nine months after the child becomes eligible for school. There is weaker evidence of an even smaller effect of eligibility for part-time nursery education on lone parents' labour supply.

These effects are small in comparison to the proportion of lone parents with children around school-entry age who are leaving welfare and entering employment over time anyway, a finding which is pertinent to the new government's plan to remove entitlement to Income Support for lone parents whose youngest child is aged five or over. The results suggest that eligibility for full-time primary education (corresponding to a relatively large childcare subsidy) does not precipitate a large increase in labour market activity around age five. Moreover, they suggest that the expansion of public education programmes to younger disadvantaged children – such as the recently announced policy of extending free nursery education to disadvantaged two year olds – may not by itself encourage many low income lone parents into work (although, of course, this is not its primary aim).

It is interesting to compare the findings of this report to those of other programmes affecting lone parents, such as In Work Credit, New Deal for Lone Parents and Work Focused Interviews. Brewer et al (2009) report that, after 12 months of being potentially eligible for In Work Credit, an extra 1.6 percentage points of potentially eligible lone parents had left benefit. Cebulla et al (2008) calculated the impact of the New Deal for Lone Parents on all lone parents on benefit to be 1.7 percentage points after nine months. They also reported that, after 12 months, the impact of Work Focused Interviews (WFIs) was 2.0 per cent for lone parents with youngest children aged 9–12. Eligibility for full-time primary education seems, therefore, to have an impact *on lone parents' labour supply* broadly comparable to these three welfare-to-work programmes, but at vastly greater cost. (Of course, the main aim of universal education is to improve children's outcomes rather than to increase parents' labour supply.)

1 Introduction

The link between the availability or price of formal childcare and maternal employment is of considerable policy interest, but understanding it poses significant technical challenges.¹

The policy interest arises because most OECD countries provide significant financial support for childcare (as well as regulating care providers to ensure minimum standards), particularly of pre-school children, through direct provision of group childcare, subsidies to private and not-for-profit providers, or cash payments or tax breaks to parents using childcare.² The policy goals vary across countries, but will usually be a combination of promoting children's development and allowing parents to engage in paid work. So policy-makers need to know not just how childcare can affect children's development but also how the availability or price of formal childcare relates to parental employment.

But estimating the link between the availability or price of formal childcare and parental employment poses significant technical challenges. Brewer & Paull (2004), drawing on Blau (2003) and Blau & Currie (2004), argue that this is due to a combination of inadequate data (the quality of formal care is rarely observed in large-scale surveys, and the quality, cost and availability of informal care never observed), misspecification of parents' underlying choice set (many studies reviewed in Blau & Currie (2004) assume parents choose between freely-available informal care and formal care, whereas many childcare users use both formal and informal care, and some have no informal care options), and a lack of plausible instruments to overcome selection bias (wages are observed only for those who work, and childcare prices and quantities are observed only for those who choose to use formal childcare).

¹ By childcare, we mean what is referred to in the UK as "formal childcare", i.e. care provided by someone who is not a relative or family friend. This could be group care (or centre-based care), or care provided by a qualified carer in the carer's own home (or, in the UK, care provided by a qualified person in the child's own home).

² For example, the UK government provides financial support for childcare amongst working parents through the childcare element of its Working Tax Credit (see <http://taxcredits.hmrc.gov.uk/Qualify/WhatAreTaxCredits.aspx>), and also offers direct provision, particularly targeted at disadvantaged families, through Sure Start Children's Centres (<http://www.dcsf.gov.uk/everychildmatters/earlyyears/surestart/whatsurestartdoes/>). See Section 2.3 for more details.

Despite these difficulties, many studies have sought to estimate the elasticity of maternal employment with respect to the price of formal childcare, mainly using regional variations in the price of childcare as an instrument.³ Anderson & Levine (1999) report that “these studies do uniformly find a negative relationship between childcare costs and mothers’ employment”. But, reviewing much the same studies, Blau & Currie (2004) find that neither sample composition nor data sources can explain the considerable variation in the existing estimates, implying that “specification and estimation issues most likely play an important role in producing variation in the estimates”. They conclude that “it is risky to generalize from only three studies, but the fact that the studies that accounted for unpaid [i.e. informal] child care in ways consistent with the existence of an informal care option [Ribar (1995), Blau & Hagy (1998), Tekin (2003)] produced small elasticities [of mothers’ employment with respect to the price of childcare] suggests that the true elasticity may be small”. There is also little consensus as to whether such elasticities are greater for lone mothers or married women.

Given these difficulties, economists have tried to use policy variation as a way of generating instruments for the price or availability of formal childcare. For example, Lefebvre & Merrigan (2008) and Baker et al (2008) both study an expansion of universal, highly-subsidized childcare for pre-school children that took place in Quebec in the 1990s, using other provinces in Canada as a comparison group. Using different data sources, both find a significant impact on maternal employment.

A related strand of literature has sought to estimate the impact of children beginning full- or part-time education on maternal labour supply. This is of interest in its own right (for example, in estimating the costs and benefits of publicly-funded education systems, but also in thinking about when to apply work-search requirements to lone parents receiving welfare, as we discuss in the conclusion), but such impacts have also been seen as relevant to the question of whether formal childcare for pre-school children affects parental labour supply. Brewer & Paull (2004) note that “the sudden provision of free childcare during

³ Note that most studies refer almost exclusively to the effect of childcare on maternal (rather than parental) employment.

school hours should encourage mothers to enter work or extend their working hours...yet reality may not be so simple: suitable childcare to cover the remaining hours may not always be available or may create too many complexities in differing and irregular arrangements. In addition, a child starting school brings a new involvement in school life for the parent as well as the child, potentially generating new responsibilities for the mother outside the formal labour market” (p10). Despite these competing effects, the appeal of examining the impact of children beginning full- or part-time education on parental labour supply is that school (or pre-school) admissions policies can provide convincing natural experiments that can tell us about causal impacts; furthermore, as entitlement to public education tends to be universal, there are no selection problems of the kind that might arise by studying a means-tested programme (Gelbach, 2002).

While a number of studies make use of geographical or time variation in the introduction or expansion of pre-school or kindergarten programmes (see, for example, Schlosser, 2006, for Israel, and Cascio, 2009, for the US), the principle behind many of these studies is to make use of date-of-birth cut-offs that exist when schools or school districts determine when a child can or should begin full-time education. These administrative rules mean that a child’s birthday (or month or quarter of birth) or age can be used as an instrument for attending full-time education (as in Gelbach, 2002, as we explain below), or that researchers can use a regression discontinuity design (as in Berlinski et al, 2009, Fitzpatrick, 2010, and this study) exploiting the fact that admissions rules mean that children born a day apart are eligible to start school up to a year apart.

As we discuss in more detail in Section 3, our study builds on and develops the findings in Gelbach (2002), Berlinski et al (2009) and Fitzpatrick (2010). We examine the impact of eligibility for publicly-funded, free, full-time primary education (relative to publicly funded, free, part-time nursery education) on the labour supply of lone parents in England whose youngest child turns four between 2000 and 2004⁴. We make use of birth date cut-offs in eligibility rules: in the areas of England we focus on, most children are eligible to start school in the academic year which starts after they turn four. So, for example, a child born on 31

⁴ Full-time primary education is broadly equivalent to kindergarten, and part-time nursery education is broadly equivalent to pre-K in the US.

August 2006 will be eligible to start school on 1 September 2010 (aged 4 years and 1 day), but a child born just one day later on 1 September 2006 will be eligible to start school a whole year later on 1 September 2011 (aged 5 years). We also examine the impact of eligibility for publicly-funded, free, part-time nursery education, to which children in England become entitled from the beginning of the term after they turn three.

We examine the impact of this eligibility on lone parents (predominantly mothers) receiving welfare benefits who have no younger children using administrative data on welfare receipt and employment spells. Clearly we cannot claim that our results are informative about the likely response of all mothers with three or four year olds in England. But lone mothers with no younger children are the group that Cascio (2009) and Fitzpatrick (2009) identify as being the most responsive to starting (pre-)kindergarten in the US. And there are several advantages of using administrative (rather than survey) data: accurate measures of the children's date of birth and home address (which we use to determine the relevant school admissions policy), continuous (not point-in-time) measures of outcomes (whether receiving welfare and/or in employment), and a 100% sample. Indeed, the key advantage of our study compared to previous ones is that we can estimate the precise timing (relative to the date on which children become eligible) of the impact of eligibility for full- or part-time public education, including testing for anticipation effects, something that to our knowledge no other studies have been able to do.

The disadvantage of our study compared to previous ones is that we have no direct measure of school or nursery enrolment, which means that our estimates are of the intention-to-treat: we estimate the causal impact of being entitled to publicly-funded, free, full-time education (or publicly-funded, free, part-time nursery education), and not the causal impact of attending school or nursery, or being induced to attend school or nursery, as in Gelbach (2002) or Berlinski et al (2009). However, we argue that our estimates are close to the causal impact of attending full-time primary education (relative to part-time nursery education), or of attending part-time nursery education, because very few lone parents on welfare will be using private schools or private childcare facilities. Moreover, it is not at all common for parents in England to hold their children back a year, as can happen in other countries: the majority of children will therefore be in full- or part-time education of any

kind if and only if they are entitled to publicly-funded, free, full-time primary education or publicly-funded, free, part-time nursery education.

Using a regression discontinuity approach, we find that, amongst those receiving welfare when their youngest child is aged approximately three and a half, eligibility for full-time primary education (relative to part-time nursery education) increases the proportion of lone parents off welfare and in employment by a small but significant margin that peaks (at around 2 percentage points, or 10-15 per cent) eight to nine months after the child becomes eligible (aged approximately 4 years and 9 months). Moreover, we find that these effects do not start to emerge until some four to six months after eligibility, which suggests that lone parents may not start looking for work until their child enters school. This indicates that some previous estimates (notably those of Gelbach, 2002, and Fitzpatrick, 2010) may underestimate the effect of (pre-)kindergarten entry on mothers' labour supply, as they are only able to consider outcomes seven and five months respectively after the children have started school. Amongst those receiving welfare when their youngest child is aged approximately two and a half, we find some evidence of a slightly smaller effect of eligibility for part-time nursery education on the proportion of lone parents off welfare or in employment.

We make use of a number of placebo tests to verify our results. In particular, we compare outcomes amongst parents of children who are either too young or too old to be affected by the school or nursery entry discontinuity (including those turning two, six and ten). We also compare outcomes amongst parents of children turning four who are born either side of a discontinuity which has no bearing on school entry. As hoped, we find virtually no difference in welfare receipt or employment outcomes for any of these groups, which provides reassurance that our main finding – of a small but significant effect of entitlement to full-time primary education (relative to part-time nursery education) on welfare receipt and employment outcomes amongst low income lone parents – is valid.

This paper now proceeds as follows. Section 2 provides background information about the provision of childcare and public education in England, as well as some information about employment rates and childcare use amongst lone parents. Section 3 outlines our

identification strategy and modelling approach, and describes the datasets that we use and how we select our sample. Section 4 describes our results and compares them to those from previous studies. Section 5 concludes.

2 Institutional Background

Provision of full-time public education in England

The academic year in England runs from 1 September to 31 August, and is split into three terms (September to December; January to April; May to August). Parents are statutorily obliged to send their child to school (or provide alternative appropriate means of education such as home schooling) from the school term that begins after the child's fifth birthday, earlier than in most OECD countries. This is known as the statutory school age. However, the age from which children are entitled to attend publicly-provided, free-to-access primary education is not determined by the national government; instead, it is up to each local authority⁵ – and in some cases (as we discuss below), individual schools – to decide the age at which to admit pupils.

For the overwhelming majority of children, an entitlement to attend publicly-provided, free-to-access primary education is in place before the statutory school age. While parents are free not to take advantage of this entitlement while their children are below the statutory school age, anecdotal evidence suggests that it is difficult for parents to request alternative entry dates, and parents who do not use their entitlement at the earliest possible date may face a more restricted choice of schools, as there are legally-binding limits on class sizes for children in primary schools. Moreover, in contrast to the US – where it is common practice for parents of children who are young in their school year to hold them back (known as

⁵ There are around 150 local authorities in England.

academic “red-shirting”⁶) – parents in England appear to regard it as advantageous for their child to start school as early as possible.

The most common admissions policy adopted by local authorities in England (covering around 50% of school entrants) entitles all children to start school in the September after they turn four (we refer to this as Policy 1). So, for example, all children born between 1 September 2005 and 31 August 2006 will be eligible to start school on 1 September 2010. It is clear that such a policy gives rise to considerable variation in the age at which children start school: two children born only one day apart – on 31 August 2006 and 1 September 2006 – will be eligible start school one year apart (the former on 1 September 2010, the latter on 1 September 2011).

The second most common admissions policy (covering around 15% of school entrants) entitles children born between 1 September and 28/29 February to start school in the September after they turn four, and children born between 1 March and 31 August to start school in the January after they turn four (we refer to this as Policy 2). In this case, a child born on 31 August 2006 would be eligible to start school in January 2011, while a child born just one day later on 1 September 2006 would be eligible to start school in September 2011, a gap of eight months. A further discontinuity also exists under this policy: a child born on 28 February 2006 would be eligible to start school in September 2010, while a child born just one day later on 1 March 2006 would be eligible to start school in January 2011, a gap of four months.

Policy 2 areas are, on average, more deprived than Policy 1 areas, with lower average employment rates, higher Index of Multiple Deprivation scores⁷ and a lower proportion of lone parent owner occupiers. Lone parent welfare claimants living in Policy 2 areas tend to be older, have more children, are more likely to be from an ethnic minority background, and

⁶ <http://nces.ed.gov/pubs2006/2006064.pdf> suggests that around 6% of children start kindergarten a year late. These children are more likely to be male, white and from families with higher educational qualifications than those who start kindergarten on time.

⁷ This is a measure of deprivation available at Super Output Area (SOA) level (comprising approximately 700 households) in 2004 and makes use of information from seven different domains: income; employment; health and disability; education, skills and training; barriers to housing and services; living environment; and crime.

have typically spent a smaller proportion of the past three years in work than lone parent welfare claimants living in Policy 1 areas.⁸

Of course, not all children in England will attend public (state) schools (although the vast majority of children in our sample are likely to do so). Moreover, some state schools (non-community schools, catering for around 30% of primary school children in England⁹) operate their own admissions policy (independent of the local authority policy). We discuss below what this means for our empirical work.

Provision of part-time nursery education in England

Local authorities in England are obliged to offer free-to-access nursery education for all three and four year olds (usually in 2.5 hour sessions, five days a week, over the course of the school year).¹⁰ This entitlement has existed for all four year-olds since 2001, and was phased in for three year olds over the period covered by our study, with 63 of the most deprived local authorities (covering approximately 86% of our sample) given funding to provide free part-time nursery places for three year olds from 2000.¹¹ Parents could either make use of publicly-provided, free-to-access options, which were generally over-subscribed, or, if they did not want to use (or could not access) these places, they were entitled to a voucher of a (supposedly) equivalent value which they could use at centre-based childcare facilities run by private sector or not-for-profit organisations. This scheme is not limited to working families and is not subject to an income test; its primary aim is to

⁸ Source: authors' calculations based on a sample of lone parents whose youngest child turns four between 2000 and 2004, described in more detail in Section 3.4.

⁹ Source: authors' calculations based on school census data for all children attending state primary schools in England. Such schools exist within each local authority.

¹⁰ There are similar programmes in Wales, Scotland and Northern Ireland as well.

¹¹ These local authorities are: Durham, Gateshead, Middlesbrough, Newcastle Upon Tyne, North Tyneside, South Tyneside, Stockton on Tees, Sunderland, Blackburn with Darwen, Blackpool, Bolton, Halton, Knowsley, Liverpool, Manchester, Oldham, Rochdale, Salford, Sefton, St Helens, Tameside, Wirral, Barnsley, Bradford, Doncaster, Kingston Upon Hull, Kirklees, Leeds, North East Lincolnshire, Rotherham, Sheffield, Wakefield, Leicester, Nottingham, Birmingham, Coventry, Stoke on Trent, Telford and Wrekin, Walsall, Wolverhampton, Camden, Hackney, Hammersmith and Fulham, Haringey, Islington, Lambeth, Lewisham, Newham, Southwark, Tower Hamlets, Wandsworth, Westminster, Barking and Dagenham, Brent, Ealing, Greenwich, Hounslow, Waltham Forest, Brighton and Hove, Cornwall and Isles of Scilly, and Plymouth. Information derived from: <http://www.dcsf.gov.uk/rsgateway/DB/SBU/b000430/bulletintext2003final.pdf>.

promote child development and ensure that all children are ready to start formal schooling at the age of five, rather than to facilitate work amongst parents. Almost all four year old children either benefitted from a voucher, or were enrolled in a publicly-funded and free-to-access nursery or reception class during the period covered by our study, with the equivalent proportion of three year-olds rising from 59% to 93% between 2001 and 2004.¹²

Provision of and government support for childcare in England

To identify the relevant counter-factual for our analysis, it is important to understand the policy regime faced by those pre-school children who are not entitled to full-time primary or part-time nursery education. During the period covered by our data, there were two main options for formal childcare for pre-school children: 1) centre-based care, provided by private sector companies, not-for-profit organisations, and (rarely) directly by local authorities, and; 2) self-employed childminders, who provide non-relative care outside of the family home (almost always in the childminder's home), and who must be registered with a statutory authority to care for children under the age of 8. Many families, of course, use informal care from relatives and friends as well as or instead of formal childcare.

Aside from the provision of free part-time nursery education places (discussed above), there are two other programmes for supporting formal childcare in the UK. First, working families may be able to claim the childcare tax credit (from 2003, the childcare element of the working tax credit) which rebated up to 70% (from 2005, 80%) of spending on formal, registered, childcare (subject to a generous cap) for working families who passed an income test.¹³ Second, from April 2005, employers could pay their employees childcare vouchers of up to £50 a week free of income tax and payroll taxes: these could only be used to pay registered, formal, child carers; care by relatives or friends was not eligible.

¹² Source: <http://www.dcsf.gov.uk/rsgateway/DB/SFR/s000604/SFR43-2005.pdf>.

¹³ Entitlements to these childcare subsidies were added to a family's entitlement to the working families' tax credit (from 2003, the working tax credit), and then withdrawn in the same way as those credits. This means that characterising how much a particular family could receive in support for childcare depends upon family pre-tax income, the number of children and the amount spent on childcare: for further details, see <http://www.ifs.org.uk/budgets/gb2005/05chap9.pdf>.

Employment rates and childcare use amongst lone parents in England

To put our sample into context, 27 per cent of families whose youngest child turned four between April 2001 and March 2005 were headed by a lone parent. Amongst lone parents with children of this age, 43 per cent were in work and 54 per cent were receiving welfare benefits.^{14,15} This employment rate is low by international standards and may be partly explained by the absence of work requirements for the vast majority of lone parents on welfare: all the lone parents in our sample would have expected to be able to remain on welfare (if their private income remained sufficiently low) until their children reached the age of 16 with no obligations to look for work or do any other work-related activities.¹⁶

In 2005, a job of 30 hours a week at the minimum wage would give gross earnings of £7,878, but a lone parent with 2 children would have a net income including all benefits and tax credits of £13,987, just above the poverty line for a family of that type in 2005-06 of £260 a week (where the poverty line is defined as 60% of median equivalised income). This was almost always greater than the total income from welfare benefits received by non-working lone parents, but the actual financial incentive to work would depend upon whether lone parents were receiving help with rental housing costs (which most were) and the size of their rents, because the programme that helps with rental costs, called Housing Benefit, is strongly means-tested against earnings. With no rental costs, a non-working lone parent on welfare would receive £8,551 a year; with a rent of £60 a week, he or she would receive £11,671 a year. This means the participation tax rate (the fraction of gross earnings lost in tax and foregone welfare payments) for this 30 hour, minimum wage job would be 31% with

¹⁴ Based on our own analysis of the Family Resources Survey.

¹⁵ By “welfare benefits” we mean either Income Support, Jobseeker’s Allowance or Incapacity Benefit. Incapacity Benefit is designed for claimants who are too ill to work. The main difference between Income Support and Jobseeker’s Allowance is that recipients of Income Support were not required to undertake any work-related activities while they had children aged 16 or under, but recipients of Jobseekers Allowance – the key benefit for the unemployed – were. Given that lone parents could choose which to claim, and would usually be entitled to identical amounts of each, only a tiny fraction of those on welfare were receiving Jobseeker’s Allowance.

¹⁶ In other words, at the time of our sample, lone parents were allowed to remain on welfare until their children reached 16. But this age cut-off began to fall in 2008, and, by 2012, lone parents whose children are all aged 5 or over will be subject to similar work-search requirements as other unemployed or disabled people.

no housing benefit, but 67% with housing benefit (and it would be higher for those paying a high rent).

Figure 1 shows how the employment rate amongst lone parents in the UK varies by age of youngest child. There is a substantial difference in the employment rate between those whose youngest child is 2 and those whose youngest child is 4, but little discernible change around the age at which children are entitled to start school. Unsurprisingly, what does change dramatically as children age is the type of childcare used by working families: Figure 2 shows that there is a 30 percentage point difference in the use of childcare between children aged 2 with working lone parents and children aged 6 with working lone parents, almost all of which comes from a fall in the use of formal childcare.

3 Methods and Data

Relationship to previous studies

Our study builds on and develops the findings in Gelbach (2002), Berlinski et al (2009) and Fitzpatrick (2010), so we start by briefly outlining the methods and findings of those studies.

Gelbach (2002) sought to estimate the impact of public school enrolment (in kindergarten) on maternal labour supply, using US Census data from 1980. A straight-forward ordinary least squares (OLS) regression of measures of labour supply on enrolment in school would give biased results, as some parents used private schools, and others delayed their child's entry to public schools. Gelbach argued that quarter-of-birth acts as a valid instrument for whether a five-year-old child is enrolled in public school, and he then uses it in regressions of various measures of labour supply on enrolment in public school, finding that public school enrolment increases labour supply for married mothers, and lone mothers with no younger children. But, as Fitzpatrick (2010) argues, the issue with Gelbach's results is that maternal labour supply is measured on the same calendar date for all mothers, and so the children are all of different ages: this means that quarter of birth will be an invalid

instrument if a mother's labour supply is related to her children's age independently of the impact of being enrolled in public school.

Fitzpatrick (2010), in an approach very similar to our own, studies a related situation by exploiting date-of-birth cut-offs in eligibility for publicly-subsidised pre-kindergarten (pre-K). She argues that administrative rules create a sharp regression discontinuity, with children born on or before 1 September being different from those born on or after 2 September in that only the former are eligible for pre-K.¹⁷ Using information on the exact date-of-birth of children of mothers in the US Census, she is able to use the regression discontinuity to estimate the causal impact of eligibility for universal pre-K on pre-school enrolment and maternal labour supply. The approach adopted by Berlinski et al (2009) is very similar, exploiting the discontinuity caused by administrative cut-offs as an instrument in a regression relating pre-school attendance to maternal labour supply in Argentina.

The main difference between Gelbach and the subsequent two studies is that, with access to the children's exact date-of-birth, Fitzpatrick (2010) and Berlinski et al (2009) can relax the assumption in Gelbach (2002) that a child's age is not directly related to maternal labour supply.¹⁸ A disadvantage common to Gelbach (2002) and Fitzpatrick (2010) is that they record labour supply outcomes at only two particular points in time (and on the same calendar date for each mother): in a reference week before the Census interview (April 1980 in Gelbach, and February 2000 in Fitzpatrick), and in the calendar year before the interview (1979 in Gelbach, and 1999 in Fitzpatrick). The latter outcomes cover a period where the children are in kindergarten/pre-K for only around one third of the time (4 out of 12 months, assuming a 1 September start date), meaning any estimated impact understates the true impact of full participation in kindergarten or pre-K. The former outcomes are measured approximately 7 months after the child started in kindergarten (or approximately 5 months after starting pre-K). This is not invalid, but gives only a glimpse of the overall

¹⁷ She also uses states which did not offer universal pre-K as additional "controls", so that the impact of pre-K is estimated as the difference in the regression discontinuity estimates of an effect in the states running the program, and those which were not.

¹⁸ Fitzpatrick (2010) reports that a replication of Gelbach's study using more recent US Census data that also uses precise date-of-birth of the children – and which can therefore relax the assumption that a child's age is not directly related to maternal labour supply – finds that public school enrolment affects labour supply only among lone mothers with no younger children: see Fitzpatrick (2009).

impact on maternal labour supply during the entire year in which some children are in kindergarten/pre-K and some otherwise-identical children are not, and gives no indication of whether any impacts occur immediately after school entry or with a lag, and whether they persist.

Our aim is to build on the findings of these previous studies by exploiting the discontinuities in eligibility for part-time nursery education and full-time primary education described above to identify the causal impact of eligibility for these types of free public education on the labour supply of low income lone parents. One advantage of our study compared to previous ones is that we are able to estimate the precise timing of any impact of eligibility by comparing outcomes up to a year after children first become entitled. However, we are unable to observe school or nursery enrolment in our data. This means that we are in essence identifying the intention-to-treat effect of living in an area in which the local authority policy allows children to start part-time nursery or full-time school at a certain age. And, when considering the impact of eligibility for full-time primary education, it should be remembered that the relevant counterfactual for our population of interest is likely to be 2.5 hours of free nursery education per day throughout the majority of this period (as low-income lone parents are unlikely to be purchasing additional hours of formal childcare). Thus, these estimates should be regarded as the causal impact of living in an area in which the local authority policy offers children approximately 4 additional hours of free childcare per day during term time.

The regression discontinuity model

We adopt a regression discontinuity (RD) design (Imbens & Lemieux, 2008). In a model in which there is a sharp cut-off based on age, the principle is that, if the underlying relationship between the outcome and age is smooth (continuous), then individuals observed just above and just below the cut-off should have very similar observed and unobserved characteristics; within this group, then, the allocation of treatment status is almost as good as random (Hahn et al, 2001; Lee, 2008). Of course, age is not measured

strictly continuously, and so identification relies on a parametric specification of the underlying relationship between age and the outcome (Card & Lee, 2008).

Administrative date-of-birth cut-offs should lead to sharp discontinuities (Hahn et al, 2001), but, in this case, the discontinuity is fuzzy, mostly because of the 30 per cent of children who attend state schools that are responsible for their own admissions policies.¹⁹ However, the discontinuity is not that fuzzy: Figures 3a to 3c, based on school census data of the population of students eligible for free school meals²⁰ who joined public (state) schools in England between academic years 2001-02 and 2004-05, show that a very high proportion of children eligible for free school meals (78 per cent, on average) started school at the expected time, presumably because many non-community schools find it expedient to synchronise their admissions policies with that of the relevant local authority. Expected start date is also a strong and significant predictor of actual start date in a simple regression model.²¹

To justify the use of the RD approach, it is customary to present a number of graphical analyses. First, as parents have some influence over the date of birth of their children, and given that it is widely known that 1 September represents a discontinuity in school admissions policies, the distribution of births around the cut-off may not be continuous (McCrary, 2008). Figure 4 therefore shows the number of children in our sample born on each day in a 120 day window around our main cut-off. This figure suggests that while there are slightly fewer children born just before than just after the 1 September cut-off – which would be consistent with parents timing births so that their children start school later (as the oldest in their academic year)²² – this difference is small relative to the variation in birth rates in the sample as a whole.²³

¹⁹ Our data do not tell us which school children attended, so there is no way of dropping children who attend such schools from our sample.

²⁰ The children of Income Support claimants will be a subset of those who are eligible for free school meals.

²¹ Unfortunately, we cannot use the data from the school census to estimate a two-sample 2SLS estimator as the school census does not identify which children are in lone parent families.

²² Gans & Leigh (2009) show striking evidence that parents have some ability to time births even given the date of conception. Lalive et al (2010) is another example of a sharp regression discontinuity design based on a date of birth cut-off.

²³ Section 4.5 presents a variant of our analysis which omits children born up to a week either side of the cut-off.

Second, if some families are more likely to time conception or birth than others, then there may be differences in observed or unobserved characteristics amongst families with children born either side of the cut-off. Appendix A illustrates graphically how some of the key observable characteristics vary by date of birth, while Table 1 presents differences in the mean values of these characteristics between families with children born up to 60 days before and 60 days after the 1 September cut-off. None of the Figures exhibit any obvious discontinuity around 1 September, and Table 1 suggests that there are few significant differences in terms of average characteristics between these two groups.^{24,25} We account for these small differences in observable characteristics by including individual and local area controls in our regressions.²⁶

Econometric specification

To operationalise this RD approach, ideally, we would estimate a model relating parents' labour supply to child's enrolment in school:

$$Y_{ijcm} = \alpha S_{ijcm} + \beta_1 X_{1ijc} + \beta_2 X_{2ijcm} + \mu_j + \delta_c + \varepsilon_{ijcm} \quad [1]$$

where Y_{ijcm} is some labour supply outcome for parent i in local authority j in cohort c in month m ; S_{ijcm} is an indicator for whether the parents' youngest child is in school in month m ; X_{1ijc} is a vector of individual characteristics that do not vary over time, such as gender,

²⁴ There are some differences in terms of the age of the parent, presumably reflecting the fact that children born before 1 September are on average two months older than children born after 1 September when they are sampled, on 31 March. However, omitting controls for "age of parent" had no discernible impact on our estimates.

²⁵ These results are confirmed by estimating equations analogous to (3) in Section 3.3 using these characteristics as outcome variables (and no other regressors).

²⁶ The full set of controls in our models includes: gender, ethnicity, age, number of children, age of youngest child relative to cut-off, employment and welfare histories, an indicator for the amount of Income Support received (as a proxy for income), past participation in a particular voluntary welfare-to-work programme (the New Deal for Lone Parents), an indicator of disability, the proportion of formal childcare places available in the lone parents' local area, their local area deprivation score, their local unemployment rate, the proportion of lone parents in their local area who are professionals (as a proxy for their own socio-economic status), and the proportion of workless lone parents in their area with particular education levels (as a proxy for their own education level). We also include a set of local authority dummies and a set of cohort dummies.

ethnicity and employment and welfare history at the point of selection into our sample; X_{2ijcm} is a vector of characteristics that are allowed to vary over time, such as the local unemployment rate; μ_j is a set of local authority dummies; δ_c is a set of cohort dummies; and ε_{ijcm} is an error term.

However, S_{ijcm} may be endogenous (if, for example, parents choose to hold their children back, or choose to access the private sector). The challenge we face, as did Gelbach (2002), Fitzpatrick (2010) and Berlinski et al (2009), is thus to find an instrument which induces exogenous variation in S_{ijcm} but has no direct effect on Y_{ijcm} . As outlined above, our approach is to make use of several birth-date discontinuities that arise in the English education system, whereby children of approximately the same age start school several (up to 12) months apart. The main discontinuity we exploit compares children born either side of the academic year cut-off of 1 September. Let A_{ijc} define a child's day of birth relative to 1 September, such that it equals 0 on 1 September, 1 on 31 August, -1 on 2 September, and so on. A potential instrument for school enrolment is the indicator variable:

$$Z_{ijc} = 1 \{A_{ijc} > 0\} \quad [2]$$

where $Z_{ijc} = 1$ if the child is born on or before 31 August and 0 otherwise.

Berlinski et al (2009) use such an instrument to estimate a two-stage least squares estimate of α . But S_{ijcm} is not observed in our data, and so we estimate a reduced-form version of [1]:

$$Y_{ijcm} = \alpha_0 Z_{ijc} + \alpha_1 A_{ijc} + \alpha_2 A_{ijc} Z_{ijc} + \beta_1 X_{1ijc} + \beta_2 X_{2ijcm} + \mu_j + \delta_c + \varepsilon_{ijcm} \quad [3]$$

This estimates α_0 , the impact of eligibility for full-time primary education (relative to part-time nursery education) on parental labour supply.²⁷ Following Berlinski et al (2009) and Fitzpatrick (2010), we control linearly for child's age in days, allowing it to have differential

²⁷ Note that we run separate regressions for each monthly outcome. Our main findings still hold up if we use seemingly unrelated regressions to take account of the fact that the errors may be correlated over time. We have also experimented with an individual random effects model, although this was less successful (as we have few time varying characteristics), and in any case we might be concerned about the correlation between the individual effects and our characteristics of interest.

effects either side of the cut-off. Following Card & Lee (2008), we cluster standard errors by day of birth (as is also done by Fitzpatrick (2010) and Berlinski et al (2009)).

Data

We use a 100% sample of administrative records, held by the UK Department for Work and Pensions, which record information about welfare receipt and time spent in paid employment for all individuals who received a welfare payment or participated in a welfare-to-work programme in Great Britain between June 1999 and March 2007.^{28,29} This data allows us to construct detailed employment and welfare histories, as well as monthly outcomes. Being administrative data – collected for the purposes of administering welfare payments or paying income tax – it contains relatively limited information on personal characteristics, but does record information such as age, gender and ethnicity.

We supplement this data with a more detailed record of the personal circumstances of individuals who claimed a particular means-tested welfare payment – Income Support – over the same period. Income Support is available to individuals who are working no more than 15 hours a week, have sufficiently low levels of financial capital, and a sufficiently low weekly income.³⁰ Moreover, the level of Income Support available to a particular individual

²⁸ Technically, the employment data records spells where the individual was potentially liable to pay income tax, either through their earnings or receipt of a taxable state benefit, so may miss periods of part-time, low paid work (for example, an individual working 16 hours per week at the minimum wage in the UK would not be liable for income tax). This would suggest that we might underestimate the proportion of individuals in employment using this data. However, there is actually strong evidence that the data *overestimates* the number of people in employment, due to inaccuracies in recording employment start and end dates. If the tax year during which the job started (ended) is known, but the day is not, then the start (end) dates are coded as those of the start (end) of the tax year, 6 (5) April; if the end date is entirely unknown, then the job may be regarded as ongoing. Both issues lead to a significant overstatement of the number of individuals in employment at any given time. While we have cleaned the data to the best of our ability (for example, by using known welfare claim start dates to infer the end date of an apparently ongoing job), it is not possible to entirely correct for this issue. As we are primarily concerned with *differences* in employment rates, however, this type of measurement error will matter only to the extent that it varies systematically between parents of children born in different months. A priori, there is no reason to expect that it should. See Brewer et al (2009) for further discussion, including details of the data cleaning process and another example of the use of this data.

²⁹ The data is not publicly available, and this project was done under a contract with the data owners, the Department for Work and Pensions.

³⁰ Many of the income-related programmes in the UK welfare system use hours rules to enforce a dichotomy between welfare benefits which are aimed at families where no adult is in work, and tax credits which are

depends on their personal circumstances – including whether or not they have a partner, how many children they have and the age of their youngest child – with all changes in circumstances recorded in this file. Importantly, this means that we have access to full date of birth of youngest child for all lone parents claiming Income Support.³¹

This file also provides us with the home postcode of the claimant. We use home postcode for two purposes: firstly, to map in very local area information about the number of formal childcare places on offer, and the local unemployment rate, both of which we might expect to affect the likelihood of a lone parent finding a job and leaving welfare.³² Secondly, and more importantly, we use home postcode to map in local authority admissions policy information. This data was collected retrospectively by the authors for a previous study, and contains details of school admissions policies in England from 1989 to 2008: see Crawford, Dearden & Meghir (2010) for more details and another use of this data.

As we only observe information about admissions policies in England, we restrict our attention to welfare recipients who are resident in England. We further restrict ourselves to claimants of Income Support as these are the only individuals for whom we observe date of birth of youngest child, and to lone parents, as past studies have suggested that they are more responsive than mothers with partners.

To ensure that we have a reasonably lengthy period of employment and welfare history prior to sample selection, as well as a relatively long period over which to assess outcomes, we select individuals whose youngest child turns four between 30 November 2000 and 29 November 2004, and who were on Income Support on 1 March in the year in which their youngest child turned four: this allows us to observe, for all cohorts, 18 months of

aimed at families where at least one adult is in paid work. Non-working lone parents would be entitled to other cash payments, principally child benefit, (from 2003) child tax credit and support for rental costs and local taxes (through housing benefit and council tax benefit). Some examples of the financial incentives to work faced by lone parents can be seen in Brewer, Saez & Shephard (2010) or Bell et al (2007).

³¹ We do not observe the date of birth of older children.

³² Of course, there is no a priori reason to suppose that lone parents of children born in different months systematically locate in areas with different characteristics, but we include such information to improve the precision of our estimates.

employment and welfare history, and three years of monthly employment and welfare outcomes.^{33,34} This gives us a total of 214,305 individuals.

As a result of our regression discontinuity approach to identification, we restrict attention to individuals born immediately either side of each of our cut-offs of interest (primarily 1 September and 1 March). Table 3 provides some indication of the sample sizes we use when analysing particular admissions policies, using individuals born up to 14, 30, 60 (our main specification) or 90 days either side of each cut-off.

To estimate the effect of eligibility for part-time nursery education on the labour supply of low income lone parents, we compare children born either side of a 1 September, 1 January or 1 April discontinuity. As free part-time nursery places for three year olds were phased in over our period of interest, we do so using two samples: first, we select individuals whose youngest child turns three between 1 November 2000 and 31 October 2004, who were on Income Support on 1 March of the year in which their youngest child turned three and who live in one of the 63 local authorities given funding to provide free part-time nursery places ahead of schedule; second, we select individuals whose youngest child turns three between 1 November 2004 and 31 October 2005 and who were on Income Support on 1 March of the year in which their youngest child turned three. In both cases, we follow these individuals for a year after the older children become eligible for part-time nursery education (i.e. up to the point at which they become eligible for full-time primary education). Table 2 provides details of these sample sizes.

³³ For individuals born close to our main cut-off (1 September), this means we sample lone parents who are on welfare when their youngest child is approximately three years and six months old.

³⁴ When considering the outcomes of parents of children turning two, six and ten as part of our placebo tests, we choose our sample in exactly the same way, i.e. we select individuals whose youngest child turns two/six/ten between 30 November 2000 and 29 November 2004 and who were on Income support on 1 March of the year in which their youngest child turned two/six/ten. We discuss the samples we use to analyse the effect of eligibility for part-time nursery education on lone parents' labour supply in Section 4.3. Table 2 provides sample sizes for each of these groups.

4 Results

Policy 1 areas

Our identification of the effect of eligibility for full-time primary education (relative to part-time nursery education) on parents' labour supply in Policy 1 areas arises from a comparison of children born either side of a 1 September cut-off, where the older children (those born in July and August in our main specification) are eligible to start school 12 months earlier than the younger children (those born in September and October in our main specification).

Figure 5 plots the proportion of lone parents off welfare, monthly, from 6 months before the older children are eligible to start school to 18 months after the younger children are eligible to start school, separately for parents of children born either side of the 1 September cut-off. If there were no effect of eligibility for full-time primary education (relative to part-time nursery education) on off-flow rates from welfare (and no difference in characteristics between the two groups), then we would expect minimal differences between the lines. On the other hand, if eligibility for full-time primary education did have an effect (and there were no differences in other characteristics), then we would expect the lines to diverge during the period in which the older children are eligible and the younger ones are not, before coming together again when the younger children become eligible. (If there were anticipation effects, then we might expect the lines to diverge before the older children become eligible.) Figure 5 suggests that the welfare receipt rates amongst lone parents of older and younger children are almost identical until about three months after the older children become eligible to start school, at which point there is a (small) divergence, which begins to tail off around six months after the younger children become eligible. This suggests that there are no (or at least no differential) anticipation effects, and would be consistent with, for example, parents not starting to look for work until their youngest child starts school, giving rise to a lag before the rates of welfare receipt diverge.³⁵

³⁵ It would also be consistent with a scenario in which (some) children attend school part-time (rather than full-time) for the first few months while they "settle in". Authors' calculations based on the Millennium Cohort Study (which follows a cohort of children born in Great Britain who we would expect to start school in 2005-

Table 4 then shows estimates of α_0 from equation (3) based on the same sample, and Figure 6 plots these estimates graphically along with the 95% confidence interval. These results suggest that eligibility for full-time primary education (relative to part-time nursery education) has a small but significant effect on lone parents' welfare receipt from around six months after their youngest child becomes eligible, peaking at 1.9 percentage points (around 10 per cent) nine months after the child first becomes eligible, before falling away to approximately zero after 14 months: this is unsurprising, as all children are now eligible for full-time education (and suggests that there are no experience effects, at least in terms of welfare receipt).^{36,37}

Figures 7 and 8 and Table 5 repeat this analysis for employment outcomes. Figure 7 highlights the likely over-estimation of the proportion of lone parents in employment discussed in Section 3: around 13 per cent of lone parents were apparently in employment when sampled, when we know that they were also claiming Income Support, and therefore highly likely to be out of work.³⁸ It also shows that the effect of eligibility for full-time primary education (relative to part-time nursery education) on employment outcomes appears to kick in just after the lone parents' youngest child starts school. Moreover, this effect is larger – and lasts for longer – than the effect on welfare receipt discussed above. Table 5 and Figure 8 show that the effect of eligibility for full-time primary education

06) suggest that around 46% of children in Policy 1 areas in England start school part-time rather than full-time (25% do so in Policy 2 areas), with the vast majority (just under 75%) attending part-time for less than two months.

³⁶ Of course, after month 12, our estimates cannot be interpreted as the impact of eligibility for full-time education as all children are now eligible: instead, they estimate the difference between being entitled for $M+12$ and M months.

³⁷ We do not show the other coefficients, mostly because there are dozens of regressions each with dozens of regressors. Choosing the outcome with the largest estimated impact (nine months after eligibility for welfare receipt), the other coefficients suggest that lone parents with more than one child, those of Chinese or mixed ethnic origin (relative to whites), those who have spent a smaller proportion of the past three years in work and off benefit, those who receive relatively more Income Support, those who have never participated in the New Deal for Lone Parents (NDLP), those who are also claiming Incapacity Benefit, those who have been disabled in the past three years, and those who live in areas with high unemployment rates are less likely to be off benefit; conversely lone parents of Black ethnic origin are more likely to be off benefit than whites. A full set of coefficient estimates is available from the authors on request.

³⁸ While it is possible for lone parents to be in work and still entitled to Income Support, after a small earnings disregard (£20 a week), there is a 100% withdrawal rate. Jobs paying less than £20 a week are highly unlikely to be recorded in the administrative data as they are far below the personal allowance (and therefore not liable for income tax).

(relative to part-time nursery education) on the likelihood of a lone parent being in paid employment peaks at 2.4 percentage points (around 13 per cent) eight months after eligibility, before falling away to approximately zero a further five months later (as the younger children also become eligible).³⁹ This suggests that Gelbach (2002) and Fitzpatrick (2010) may have slightly under-estimated the effect of attending (pre-) kindergarten on mothers' labour supply by observing outcomes relatively soon (five and seven months, respectively) after school entry.

Policy 2 areas

There are two distinct cut-offs in Policy 2 areas. First, as in Policy 1 areas, there is a discontinuity around 1 September. In Policy 2 areas, however, the older children are eligible to start school eight months earlier than the younger children (in January rather than September of the previous year). Second, there is a discontinuity around 1 March, where the older children (those born in January and February in our main specification) are eligible to start school four months earlier than the younger children (those born in March and April in our main specification) – in September rather than the following January.

Tables 6 and 7 present estimates of the effect of youngest child being born just before rather than just after the 1 September and 1 March cut-offs in Policy 2 areas respectively on the proportion of lone parents off welfare and in employment. For these groups, we find no consistent or significant effects of eligibility for full-time primary education (relative to part-time nursery education) on either welfare receipt or employment rates. While it is disappointing that these results do not clearly support our findings from the Policy 1 areas, both the shorter period over which to observe any effects, and the considerably smaller sample sizes, may provide at least a partial explanation.

³⁹ Choosing the outcome with the largest estimated impact (eight months after eligibility for employment), the other coefficients suggest that older, male lone parents, those with four or more children, those of Asian or other ethnic origin (relative to whites), those who have spent a smaller proportion of the past three years in work, those who receive relatively more Income Support, those who have never been on NDLP, those who have been disabled in the past three years, and those who live in areas with a high claimant count are less likely to be in employment; conversely lone parents of black ethnic origin are more likely to be in employment than whites. A full set of coefficient estimates is available from the authors on request.

Effect of eligibility for part-time nursery education

Appendix B presents estimates of the effect on lone parents' employment and welfare receipt of their youngest child being born either side of the 1 September discontinuity in Policy 1 and 2 areas using our two samples. (Results for the 1 January and 1 March discontinuities are available on request.) While there is little evidence of an effect of eligibility for part-time nursery education on lone parents' labour supply using our first sample, there does appear to be a significant effect amongst lone parents in our second sample. For example, three months after their youngest child becomes eligible for part-time nursery education, parents of older children in Policy 1 areas are 1.7 percentage points more likely to be off welfare than parents of younger children in Policy 1 areas. There also seem to be some significant effects on employment outcomes amongst lone parents in both Policy 1 and Policy 2 areas, although it is not clear whether these are lagged effects of eligibility for part-time nursery education or anticipation effects of eligibility of full-time primary education.

Subgroup analysis

We now move on to assess whether the effects of youngest child's eligibility for full-time primary education (relative to part-time nursery education) on the labour supply of low income lone parents varies according to the characteristics of the lone parent. In particular, we consider whether it differs by: 1) length of welfare claim at sample entry; 2) past participation in a particular voluntary welfare-to-work programme, the New Deal for Lone Parents (NDLP); 3) local employment rate; 4) number of children; 5) ethnicity; 6) disability status. Results for the 1 September discontinuity in Policy 1 areas by claim length and NDLP participation can be found in Appendix C; all other results are available from the authors on request.

We find that lone parents who have previously been on NDLP and those whose welfare claim has lasted for less than 12 months at the point of sample entry are more responsive to the childcare subsidy provided by entitlement to full-time primary education (relative to

part-time nursery education) than lone parents who have never previously been on NDLP or whose welfare claim has lasted at least 12 months at sample entry. For example, nine months after eligibility begins, lone parents whose youngest child is born immediately before the 1 September discontinuity in Policy 1 areas are around 4.3 percentage points more likely to be off welfare than lone parents whose youngest child is born immediately after the 1 September discontinuity if they have ever been on NDLP, compared to only 1.6 percentage points if they have not. Similarly, eight months after eligibility, the effect on employment outcomes amongst lone parents who have ever been on NDLP is 5.7 percentage points, compared to 2.0 percentage points amongst those who have not. In both cases, the estimates are significantly different from each other, and the differences by claim length are broadly similar.

Brewer et al (2009) similarly found that the impact of a wage supplement was greater for lone parents who had previously participated in NDLP than those who had not. They suggested that this greater response could be because lone parents on NDLP were more likely to hear about the wage supplement, or that, since NDLP is a voluntary programme, those who sign up are lone parents with a greater underlying propensity to work and a greater responsiveness to financial incentives to work. In this case, it is not very likely that a lone parent could be unaware that their child was entitled to full-time primary education, and so the higher impact amongst lone parents participating in NDLP seems likely to be a selection effect. This would also be a plausible explanation for the differences by claim length.

By contrast, we do not find any significant differences in the effect of eligibility for full-time primary education (relative to part-time nursery education) on lone parents' labour supply by local employment rate, number of children, ethnicity or disability status.

Specification checks

We carry out specification checks on our choice of sample window, our choice of age specification and our decision to include children born up to a week either side of the discontinuity in our analysis.

To ensure that our choice of sample window does not affect our results, we have run the same analysis on welfare receipt and employment outcomes using children born up to 14, 30 and 90 days either side of the discontinuity (results for the 1 September discontinuity in Policy 1 areas are shown in Tables D1 to D3 of Appendix D; results for Policy 2 areas are available from the authors on request). These figures suggest that our finding of a small but significant effect of eligibility for full-time primary education (relative to part-time nursery education) on parental labour supply is not materially affected by our choice of sample window.

Similarly, to ensure that our choice of age specification does not affect our results, we have run the same analysis using age squared (allowing it to have different slopes either side of the discontinuity). Results for the 1 September discontinuity in Policy 1 areas are shown in Table D4 in Appendix D; results for Policy 2 areas are available from the authors on request. These figures suggest that our findings are not materially affected by our choice of age specification; while the standard errors increase (a common finding), the basic pattern remains the same, particularly for welfare receipt. (We have also run specifications using age and age squared without interacting them with the treatment effect, which makes very little difference to our findings.)

As discussed in Section 3, slightly more children are born immediately before than immediately after the 1 September discontinuity. To ensure that this discrepancy is not biasing our results, we run the same analysis omitting children born up to a week either side of the discontinuity. Results for Policy 1 areas are shown in Table D5 in Appendix D; results for Policy 2 areas are available from the authors on request. These figures suggest that our findings are not unduly biased by the inclusion of children born up to a week either side of the discontinuity.

Placebo tests

To check the validity of our results, we ran a series of placebo tests. First, we compared outcomes amongst parents of children who are either too young or too old to be affected by the school entry discontinuity: in particular, we sampled children about to turn two, six and ten (rather than about to turn four, as in our main specification). Those turning two are too young to be eligible for either full-time primary education or part-time nursery education, and those turning six or ten are already in full-time primary education, so there are no discontinuities caused by school admissions policies; we would therefore expect to see no difference in outcomes for these individuals.⁴⁰ Second, we compared outcomes amongst parents of children whose youngest child is turning four, but who are born either side of a discontinuity which has no bearing on school entry. For example, we examine the effects of being born either side of 1 March cut-off in Policy 1 areas (where it has no bearing on school entry).

Tables E1, E2 and E3 in Appendix E compare outcomes amongst parents whose youngest child is turning two, six or ten respectively, and who are born up to 60 days either side of the 1 September cut-off in Policy 1 areas⁴¹, while Table E4 compares outcomes amongst parents whose youngest child is turning four and is born either immediately before or immediately after 1 March cut-off in Policy 1 areas. We find virtually no difference in welfare receipt or employment outcomes for any of these groups.⁴² As such, these results provide reassurance that our main finding of a small but significant effect of entitlement to full-time primary education (relative to part-time nursery education) on welfare receipt and employment outcomes amongst low income lone parents is valid.

⁴⁰ Entitlement to benefits and tax credits for children is constant for children aged 1 to 16.

⁴¹ Results for Policy 2 areas are available from the authors on request.

⁴² The significant differences in employment rates towards the end of the period of interest amongst lone parents whose youngest child is turning two are likely to reflect differences in eligibility for full-time primary education, as these children will be turning four around this time.

Discussion

How do our findings compare to those of the handful of other studies that have sought to estimate the impact of children attending full-time education on parental (largely maternal) employment?⁴³

Gelbach (2002) studied the impact of children aged four to five starting full-time education in 1980 in the US on their mothers' labour supply. He found that free public schooling increased measures of labour supply amongst lone mothers with no younger children by between 6 and 24 percent, and reduced welfare receipt by 10 percent, but that there was no statistically significant impact on lone mothers with a younger child.⁴⁴ The estimated impact on the outcomes closest to ours suggest that employment in the week before the Census rose by 5 percentage points (equivalent to a 10 percent rise in the number of lone mothers in work) and that the fraction who received welfare in the previous year fell by 4 percentage points (also a 10 percent rise).⁴⁵ Fitzpatrick (2009) repeats this analysis using the 2000 Census and finds significant impacts on maternal labour supply only for lone mothers with no younger children.

Fitzpatrick (2010) studies the impact of universal entitlement to free pre-K on various measures of mothers' labour supply in Georgia and Oklahoma.⁴⁶ She finds that entitlement to pre-K increases pre-school enrolment by 7.2 percentage points, or 12-14 percent, but that it has little discernable impact on maternal employment; for both findings, there are no statistically significant differences between lone mothers and married mothers.⁴⁷ Berlinksi

⁴³ As we mentioned above, there are many papers which attempt to estimate the link between the price of formal childcare (usually for pre-school children) and maternal employment: see Blau & Currie (2004) for a review, and Brewer & Paull (2004) for a discussion of what these mean for the UK.

⁴⁴ The impact on married women was between 6 and 15 percent, and varied little with the presence of younger children.

⁴⁵ The fractions of lone mothers whose youngest child is aged 5 who are in work or on welfare in the US in 1980 are very similar to those of the same group in the UK in the mid-2000s.

⁴⁶ Pre-K or pre-kindergarten is part-time (2.5 hours/day) or full-time (6 hours/day) during the school year and is intended for four year-olds. A UK equivalent would be somewhere between the entitlement to nursery places for three and four year olds and reception classes in infant schools.

⁴⁷ She suggests two reasons for the smaller impact found in her study compared to Gelbach's: first, that mothers' employment decisions have become less responsive to financial incentives as the maternal employment rate has risen (she uses data from 1999/2000 rather than 1979/1980, as in Gelbach's paper); second, that government support for all forms of childcare has increased, meaning that there is less difference

et al (2009) study a similar set-up in Argentina, again exploiting date-of-birth cut-offs which mean that children aged around five and born 1 day apart will be entitled to free pre-primary school a year apart.⁴⁸ They find that entitlement to pre-primary education increases enrolment by just under 30 percentage points, and that it increases the proportion of mothers in work by just under 4 percentage points (the mean employment rate of the sample is 37%): this means that, for every 100 children who start pre-primary school because of this reform, around 13 (the ratio of these two estimates, or $0.038/0.299$) mothers move into work, although this is not significantly different from zero.

We are not aware of any studies that have attempted to estimate the impact of starting school using UK data. The study coming closest is Brewer & Paull (2006), which examined the impact of a child turning five on maternal labour supply and a wide range of employment characteristics. They used longitudinal data on children born in the 1990s and early 2000s to examine changes in maternal labour supply and a range of work characteristics as children aged. They find that the maternal employment rate rises by 3.4 percentage points (4.7 percentage points for lone mothers) over a 15 month period during which children start school, almost all of which is due to families whose last child is starting school (their Table 5.7). On the other hand, they also show that the maternal (and paternal) work dynamics around the time of school entry seem little different to those experienced by parents of slightly younger or slightly older children: in other words, the rise in maternal employment over this period could simply be a general response to the aging of the youngest child, rather than a specific response to the start of school.

It is interesting to compare the impacts reported in this paper to those of welfare programmes affecting lone parents or changes to the rules of welfare benefits for lone parents in the UK. A partial summary of the estimated impact of welfare reforms affecting lone parents is given in Cebulla et al (2008), and Brewer et al (2009) estimated the impact of a temporary wage supplement programme for lone parents (known as “In Work Credit”).

in the childcare available to children who were and were not eligible to free pre-K in 2000 than there was between that available to children who were and were not eligible to free public schooling in 1980.

⁴⁸ Berlinski et al (2009) report that these are generally part-time sessions (3.5 hours a day), available 5 days a week in the school year, and generally within existing primary schools. A UK equivalent would be nursery classes in state-run infant or primary schools.

We find that, amongst those receiving welfare when their youngest children is aged approximately three and a half, eligibility for full-time primary education (relative to part-time nursery education) increases the proportion of lone parents off welfare and in employment by a small but significant margin that peaks at around 2 percentage points (or 10-15 per cent) eight to nine months after the child becomes eligible (aged approximately 4 years and 9 months). Brewer et al (2009) report that, after 12 months of being potentially eligible for a wage supplement, an additional 1.6 percentage points of potentially eligible lone parents had left welfare, and after 24 months, the figure was 2.0 percentage points. Cebulla et al (2008) calculated the impact of the New Deal for Lone Parents – a voluntary programme featuring personalised support and advice – on all lone parents on welfare benefits to be 1.7 percentage points after nine months and 1.4 percentage points after two years. They also reported that, after 12 months, the impact of Work Focused Interviews (WFIs) was 0.8 per cent for lone parents with youngest children aged over 13 and 2.0 per cent for lone parents with youngest children aged 9–12.⁴⁹ Eligibility for full-time primary education seems, therefore, to have an impact broadly comparable to these three welfare-to-work programmes, but at vastly greater cost, not least because the full-time primary education places were provided to all (or almost all) of the lone parents on welfare, but only a small minority of lone parents on welfare actually moved into work and took up the wage supplement. (Of course, it should be remembered that helping lone parents into work is not the primary aim of the provision of free public education.)

⁴⁹ Cebulla et al (2008) discussed extensively the difficulties involved in making direct comparisons, given the different approaches taken by the original evaluations, but these results are as comparable as they can be given the published data. Importantly, all express the intention to treat: they are the estimated impact on those lone parents who were exposed to the treatment, where the treatments are: a child's entitlement to full-time primary education; eligibility for a wage supplement were they to enter work; eligibility to volunteer for the NDLP; and a requirement to attend an annual Work Focused Interview. However, the estimated impacts of the three programmes are all for slightly different populations: the IWC estimates are for all lone parents whose welfare claim reaches 12 months, the NDLP estimate is for all lone parents on IS in Great Britain, and the WFI estimates are for the stock of lone parents on IS with children of various ages.

5 Conclusions

In this paper, we have argued that we can identify the causal impact of youngest child's eligibility for part-time nursery education and full-time primary education on the labour supply of low income lone parents by comparing outcomes of lone parents whose youngest child is born either side of cut-offs which determine eligibility to start school or nursery. Using a regression discontinuity approach, we find that, amongst those receiving welfare when their youngest children is aged approximately three and a half, eligibility for full-time primary education (relative to part-time nursery education) increases the proportion of lone parents off welfare and in employment by a small but significant margin that peaks (at around 2 percentage points, or 10-15 per cent) eight to nine months after the child becomes eligible (aged approximately 4 years and 9 months). Moreover, we find that these effects do not start to emerge until some four to six months after school entry, which suggests that lone parents may not start looking for work until their youngest child is eligible for school. This indicates that some previous estimates (notably those of Gelbach, 2002, and Fitzpatrick, 2010) may slightly under-estimate the effect of (pre-)kindergarten entry on mothers' labour supply by considering outcomes measured seven and five months respectively after the children start school. Amongst those receiving welfare when their youngest child is aged approximately two and a half, we find weaker evidence of a smaller effect of eligibility for part-time nursery education on the proportion of lone parents off welfare or in employment.

It is worth noting, however, that both of these effects are small in comparison to the proportion of lone parents with children around school or nursery entry age who are leaving welfare and entering employment over time anyway. This is perhaps surprising, given that we are focusing on what might be regarded as a relatively responsive group (and a group for whom other authors – for example, Cascio (2009) and Fitzpatrick (2009) – have found the largest effects), although it is worth pointing out that there may be relatively few jobs available to lone parents that fall entirely within school hours. Nonetheless, our results suggest that the expansion of public education programmes to younger disadvantaged children – such as the policy of extending free nursery education to disadvantaged two year

olds which has just been announced by the UK government (in October 2010) – may only encourage a small number of low income lone parents to return to work (although, of course, this is not its primary aim).

As we were conducting this research, the new (from May 2010) UK government announced a plan to remove entitlement for Income Support from lone parents whose youngest child was aged 5 or over (compared with the previous government's plan to do this for lone parents whose youngest child was aged 7 or over); this will mean that non-working lone parents who are not eligible for disability benefits will have to claim Jobseekers Allowance, a welfare benefit with job-search requirements backed up with the threat of sanctions for non-compliance.⁵⁰ Our findings are clearly pertinent to this decision: eligibility for full-time primary education (corresponding to a relatively large childcare subsidy) does not precipitate a large increase in labour market activity amongst this group. On the other hand, proponents of the move to require lone parents to seek work as a condition of receiving welfare benefits when their children are of school age might well say that the relatively small impacts found in our study mostly result from the lack of obligation to look for work that existed at the time our data was collected.

⁵⁰ See paragraph 1.101 of HC 61 (2010-11).

Estimates from a series of linear probability models which also include controls for: gender, ethnicity, age, number of children, age of youngest child relative to cut-off, day of week of birth of youngest child, whether youngest child born on a bank holiday, employment and welfare histories, an indicator for the amount of Income Support received (as a proxy for income), past participation in a particular voluntary welfare-to-work programme (the New Deal for Lone Parents), an indicator of disability, the proportion of formal childcare places available in the lone parents' local area, their local area deprivation score, their local unemployment rate, the proportion of lone parents in their local area who are professionals (as a proxy for their own socio-economic status), and the proportion of workless lone parents in their area with particular education levels (as a proxy for their own education level). We also include a set of local authority dummies and a set of cohort dummies. Full details of all coefficient estimates are available from the authors on request. Standard errors are robust, clustered by day of birth and shown in parentheses. These estimates are plotted in Figure 6.

Figure 1 Employment rate amongst lone parent by age of youngest child 2001-02 to 2003-04

Source: authors' calculations based on Family Resources Survey, April 2001 to March 2004.

Figure 2 Childcare usage amongst children of working lone parents by age of youngest child, 2001-02 to 2003-04

Source: authors' calculations based on Family Resources Survey, April 2001 to March 2004.

Figure 3a Actual school start dates of children eligible for free school meals who we expect to start school in September in Policy 1 areas in England between 2001-02 and 2004-05

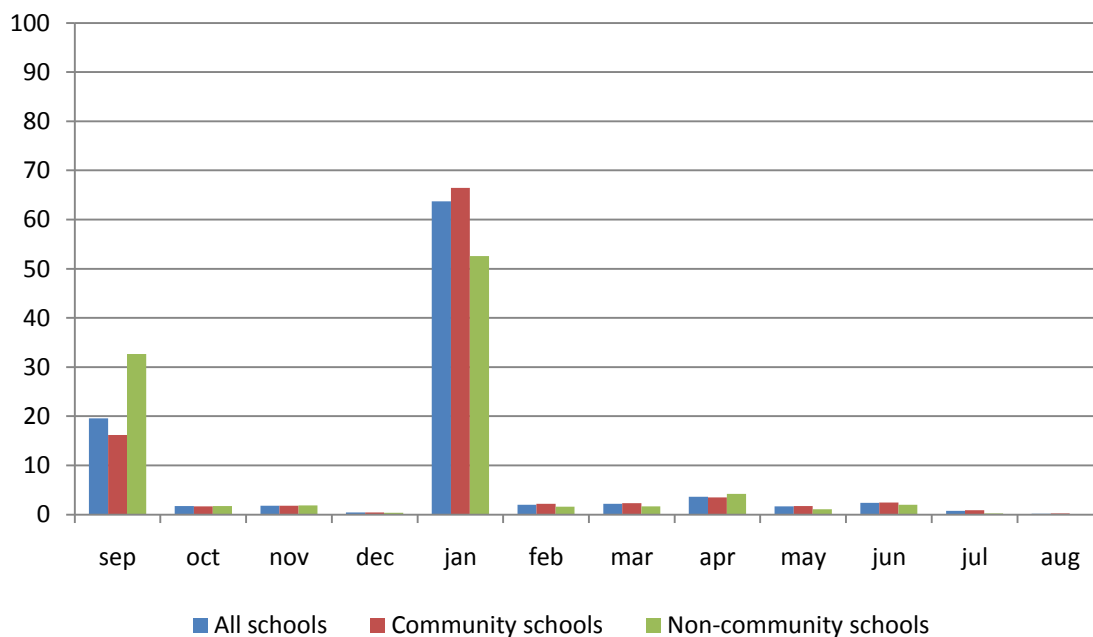

Figure 3b Actual school start dates of children eligible for free school meals who we expect to start school in September in Policy 2 areas in England between 2001-02 and 2004-05

Notes to Figures 3a-c: authors' calculations based on school census data from 2001-02 to 2004-05. Community schools (64% of the sample) are required to follow the local authority admissions policy, while non-community schools (36%) are not.

Figure 3c Actual school start dates of children eligible for free school meals who we expect to start school in January in Policy 2 areas in England between 2001-02 and 2004-05

See notes above.

Figure 4 Density of birthdates in our main sample

Figure shows number of children in our main sample born on each day relative to 1 September, accounting for the day of the week on which the child was born and whether they were born on a bank holiday (of which there is one at the end of August but none in July, September or October).

Figure 5 Proportion off welfare: comparing parents of children born up to 60 days before and after the 1 September cut-off in Policy 1 areas

Source: authors' calculations based on administrative data.

Figure 6 Effect on proportion of lone parents off welfare of youngest child being born immediately before (rather than immediately after) 1 September cut-off in Policy 1 areas

Source: estimates from a series of linear probability models which also include a full set of controls (see Table 4 for details).

Figure 7 Proportion in employment: comparing parents of children born up to 60 days before and after the 1 September cut-off in Policy 1 areas

Source: authors' calculations based on administrative data.

Figure 8 Effect on proportion of lone parents in employment of youngest child being born immediately before (rather than immediately after) 1 September cut-off in Policy 1 areas

Source: estimates from a series of linear probability models which also include a full set of controls (see Table 5 for details).

**Appendix A - Relationship Between Youngest Child's Date Of Birth And Other Characteristics
Amongst Main Sample Of Lone Parents**

Figure A1 Age of lone parent in our main sample

Figure shows age of lone parent when sampled for children in our main sample born on each day relative to 1 September (1=31 August). Figure also shows a linear trend estimated separately either side of 1 September cut-off.

Figure A2 Proportion of previous 18 months not on welfare in our main sample

Figure shows proportion of 18 months before sampling that lone parent did not spend on welfare for children in our main sample born on each day relative to 1 September (1=31 August). Figure also shows a linear trend estimated separately either side of 1 September cut-off.

Figure A3 Proportion of previous 18 months in employment in our main sample

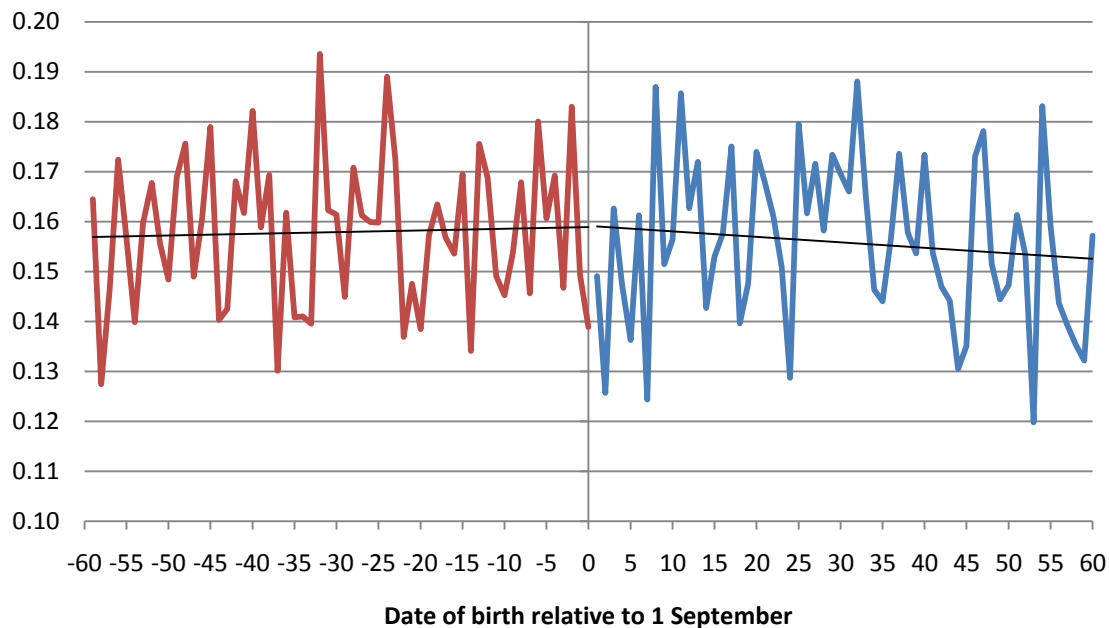

Figure shows proportion of 18 months before sampling that lone parent spent in employment for children in our main sample born on each day relative to 1 September (1=31 August). Figure also shows a linear trend estimated separately either side of 1 September cut-off.

Figure A4 Whether ever received a disability benefit in previous 18 months in our main sample

Figure shows whether lone parent ever received a disability benefit in 18 months before sampling for children in our main sample born on each day relative to 1 September (1=31 August). Figure also shows a linear trend estimated separately either side of 1 September cut-off.

Figure A5 Whether male in our main sample

Figure shows proportion of lone parents who are male for children in our main sample born each day relative to 1 September (1=31 August). Figure also shows a linear trend estimated separately either side of 1 September cut-off.

Figure A6 Whether non-white or missing ethnicity

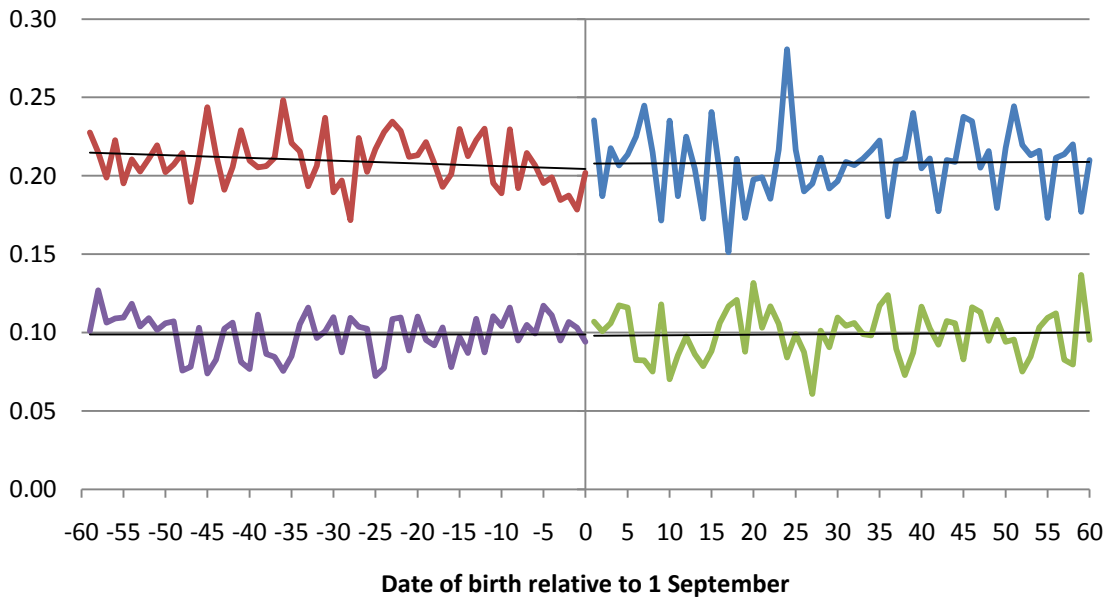

Figure shows proportion of lone parents with specified ethnicity for children in our main sample born on each day relative to 1 September (1=31 August). Top line is fraction whose ethnicity is not known; bottom line is fraction (of whole sample) with non-white ethnicity. Figure also shows a linear trend estimated separately either side of 1 September cut-off.

Figure A7 Local employment rate in our main sample

Figure also shows a linear trend estimated separately either side of 1 September cut-off (1=31 August).

Appendix B

Effect Of Eligibility For Part-Time Nursery Education

Table B1 Effect of youngest child being born before (rather than after) 1 September cut-off determining eligibility for part-time nursery education in Policy 1 areas, using sample of parents whose youngest child turns three between 2001 and 2004 and who live in local authorities given funding to provide places early

Month relative to cut-off	Approx. age	Effect on % off benefit	Effect on % in work	Month relative to cut-off	Approx. age	Effect on % off benefit	Effect on % in work
-6	2y, 6m	0.0004 [0.002]	-0.006 [0.003]	3	3y, 3m	0.009 [0.006]	0.00008 [0.006]

0	3y, 0m	0.005 [0.005]	0.004 [0.005]	9	3y, 9m	0.0007 [0.006]	-0.001 [0.005]
1	3y, 1m	0.007 [0.005]	0.001 [0.006]	10	3y, 10m	-0.002 [0.006]	-0.003 [0.005]
2	3y, 2m	0.010 [0.005]	0.002 [0.005]	11	3y, 11m	0.0004 [0.006]	-0.004 [0.006]

Estimates from a series of linear probability models which also include controls for: admissions policy area, gender, ethnicity, age, number of children, age of youngest child relative to cut-off, day of week of birth of youngest child, whether youngest child born on a bank holiday, employment and welfare histories, an indicator for the amount of Income Support received (as a proxy for income), past participation in a particular voluntary welfare-to-work programme (the New Deal for Lone Parents), an indicator of disability, the proportion of formal childcare places available in the lone parents' local area, their local area deprivation score, their local unemployment rate, the proportion of lone parents in their local area who are professionals (as a proxy for their own socio-economic status), and the proportion of workless lone parents in their area with particular education levels (as a proxy for their own education level). We also include a set of local authority dummies and a set of cohort dummies. Full details of all coefficient estimates are available from the authors on request. Standard errors are robust, clustered by day of birth and shown in parentheses.

Table B2 Effect of youngest child being born before (rather than after) 1 September cut-off determining eligibility for part-time nursery education in Policy 2 areas, using sample of parents whose youngest child turns three between 2001 and 2004 and who live in local authorities given funding to provide places early

Estimates from a series of linear probability models which also include controls for: gender, ethnicity, age, number of children, age of youngest child relative to cut-off, day of week of birth of youngest child, whether youngest child born on a bank holiday, employment and welfare histories, an indicator for the amount of Income Support received (as a proxy for income), past participation in a particular voluntary welfare-to-work programme (the New Deal for Lone Parents), an indicator of disability, the proportion of formal childcare places available in the lone parents' local area, their local area deprivation score, their local unemployment rate, the proportion of lone parents in their local area who are professionals (as a proxy for their own socio-economic status), and the proportion of workless lone parents in their area with particular education levels (as a proxy for their own education level). We also include a set of local authority dummies and a set of cohort dummies. Full details of all coefficient estimates are available from the authors on request. Standard errors are robust, clustered by day of birth and shown in parentheses.

Table D2 Effect of youngest child being born immediately before (rather than immediately after) 1 September cut-off in Policy 1 areas, using 60 day window (30 days either side of cut-off)

Estimates from a series of linear probability models, which also include controls for: gender, ethnicity, age, number of children, age of youngest child relative to cut-off, day of week of birth of youngest child, whether youngest child born on a bank holiday, employment and welfare histories, an indicator for the amount of Income Support received (as a proxy for income), past participation in a particular voluntary welfare-to-work programme (the New Deal for Lone Parents), an indicator of disability, the proportion of formal childcare places available in the lone parents' local area, their local area deprivation score, their local unemployment rate, the proportion of lone parents in their local area who are professionals (as a proxy for their own socio-economic status), and the proportion of workless lone parents in their area with particular education levels (as a proxy for their own education level). We also include a set of local authority dummies and a set of cohort dummies. Full details of all coefficient estimates are available from the authors on request. Standard errors are robust, clustered by day of birth and shown in parentheses.

Table E2 Effect of youngest child being born immediately before (rather than immediately after)
