Growth and Equity Effects of Agricultural Marketing Efficiency Gains in India

Maurice R. Landes

Mary E. Burfisher

Abstract

Agriculture is the largest source of employment in India, and food accounts for about half of consumer expenditures. Moving agricultural products from the farm to consumers more efficiently could result in large gains to producers, consumers, and India's overall economy. This analysis uses a computable general equilibrium model with agricultural commodity detail and households disaggregated by rural, urban, and income class to study the potential impacts of reforms that achieve efficiency gains in agricultural marketing and reduce agricultural input subsidies and import tariffs. More efficient agricultural marketing generates economywide gains in output and wages, raises agricultural producer prices, reduces consumer food prices, and increases private consumption, particularly by low-income households. These gains could help to offset some of the medium-term adjustment costs for some commodity markets and households associated with reducing agricultural subsidies and tariffs.

Keywords: India, agriculture, policy reform, marketing efficiency, tariffs, subsidies, households, computable general equilibrium model.

Summary

Growth in India's economy and consumer buying power has accelerated sharply since the early 1990s, when a balance-of-payments crisis instigated major liberalizing reforms to exchange rate, trade, and domestic regulatory policies. As a result, India's food demand is expanding and diversifying, but India's farm sector has not shared in the benefits of policy reform, and growth in the sector has remained sluggish. Because the farm sector accounts for a large share of total output and employment in the Indian economy, this poor performance raises concerns about India's ability to sustain accelerated income growth, reduce pervasive rural poverty, and maintain food security.

What Is the Issue?

Despite the recent robust expansion of India's economy, lagging investment and growth in its agricultural sector are raising concerns about the need for a second round of reforms to stimulate the farm economy. Reforms of agricultural trade protection and producer subsidies are frequent topics of discussion and analysis, but strong evidence supports the idea that fragmented and inefficient domestic agricultural marketing chains seriously hinder agricultural competitiveness and growth. Measures to boost marketing efficiency by reducing regulatory barriers that have impeded investment in agricultural wholesale and retail trade services may also improve conditions for low-income producers and consumers, a priority for India's policymakers. This study examines the performance of India's agricultural marketing system and analyzes the economywide implications of improved marketing efficiency that might stem from future reforms to domestic market regulations and increased investment in agricultural markets.

What Are the Major Findings?

Measures to improve agricultural marketing efficiency in India can substantially and broadly benefit India's economy. Improved marketing efficiency has the potential to generate economywide gains in output and wages, raise agricultural producer prices, reduce consumer food prices, and increase private consumption, particularly by rural and low-income households.

The broad gains from improving agricultural marketing efficiency contrast significantly with the impacts of reducing agricultural subsidies and tariffs. Indian policymakers face domestic and international pressures to reduce input subsidies and tariffs in the farm sector. But reducing subsidies and tariffs, while conferring economywide benefits, may also, at least in the medium term, create adjustment costs for labor, land, and capital markets, some commodity sectors, and households. In contrast, improved agricultural marketing efficiency can benefit the overall economy (see chart), as well as low-income households. The results of this study suggest that policy measures to improve the efficiency of domestic agricultural markets may be a valuable complement to subsidy and tariff reforms by helping to mitigate the medium-term losses that may stem from such reforms.

Economywide effects of alternative agricultural and food marketing policy scenarios in India

Greater investment and efficiency in India's agricultural supply chains also have the potential to enhance agricultural growth over the longer term. Whether new policies lead to rapid investment by modern retailers and others in transforming India's markets or the process occurs gradually, more efficient agricultural marketing is likely to strengthen consumer demand for food and other goods. More efficient domestic marketing may also boost net agricultural exports, although this result does not account for the changes in demand likely to occur as higher income growth is sustained over the longer term or for constraints on crop and livestock production that may emerge.

This analysis also does not fully assess the adjustment costs, including potential employment and income losses in some areas of the traditional marketing system, that might result from transforming India's traditional wholesale and retail markets into a more efficient sector. This transformation could lead to fewer, but larger, vertically integrated, and more technologically advanced processing and marketing enterprises. Concerns with managing these adjustment costs are central to the current debate over regulating direct foreign investment in food retailing in India. This analysis suggests, however, that although some participants in the traditional marketing system would undoubtedly face adjustment costs, the impacts on economywide wages and welfare, as well as the welfare impacts on low-income households, are positive.

For the United States, these results suggest that increasing investment and efficiency in India's agricultural markets is an important potential driver of broad-based income and demand growth in India, likely bringing long-term benefits to its trade partners. The analysis of the potential impacts of reforms to agricultural input subsidies and tariffs suggests why these issues are sensitive for India in bilateral and multilateral negotiations. At least in the medium term, reducing input subsidies lowers output of food staples, leading to reduced welfare for low-income households, while reducing tariffs imposes adjustment costs on protected commodity sectors. But, the results also suggest that measures to improve agricultural marketing efficiency, perhaps including cooperation to strengthen India's market institutions and investment climate, can help mitigate the adjustment costs faced

by some households and commodity sectors from such reforms. Further, the substantial increases in agricultural output and food consumption that arise from improved marketing efficiency in this analysis suggest the potential for positive returns to private investment—including U.S. private foreign investment—in Indian agribusiness.

How Was the Study Conducted?

The authors constructed a computable general equilibrium (CGE) model of the Indian economy. The basic model structure was developed by the International Food Policy Research Institute (IFPRI), with expanded commodity coverage, disaggregation of marketing and trade costs, disaggregation of rural and urban households by expenditure class, and other extensions added by the authors for this study. Model data were supplied by the Global Trade Analysis Project (GTAP) and official Indian sources. Model structure, extensions, and data sources are described in detail in an appendix. The study also draws on data and results from studies of India's agricultural markets conducted recently by ERS, the World Bank, and other institutions.

Introduction

Growth in India's real income has accelerated sharply since the early 1990s, when a balance of payments crisis instigated major liberalizing reforms to exchange rate, trade, and domestic regulatory policies. But, despite the resulting expansion and diversification of food demand, growth in India's farm sector has been slowing. Because the farm sector accounts for large shares of total output and employment in the Indian economy, this poor performance raises concerns about progress in reducing pervasive rural poverty, the sustainability of India's higher growth path, and the maintenance of food security. The successful reforms of the early 1990s enhanced the competitiveness and growth of India's manufacturing and service sectors, but political consensus on a "second round" of reforms to stimulate the rural sector and more directly address the needs of India's rural and urban poor has remained elusive. A major package of credit concessions and outlays for agriculture announced in the 2008/09 government budget—in advance of national elections in early 2009—was evidence of continued concern with farm sector performance.

The government has been and continues to be heavily involved in India's agricultural sector through policy interventions in the production, marketing, and trade of most major farm commodities. Most obvious—and most studied—have been India's border measures, including relatively high bound and applied tariffs and export controls for farm products, and its burgeoning subsidies on farm inputs and on producer and consumer prices of wheat and rice.¹ Less obvious—and less studied—are India's extensive array of central and state regulations that affect the movement, storage, processing, and marketing of farm commodities and that have served as disincentives for private investment in agricultural wholesale and retail marketing. As a result, India's agricultural marketing system consists primarily of small-scale, nonintegrated, and inefficient marketing enterprises that tax both producers and consumers of farm products (Landes, 2008; Landes and Gulati, 2004).

A small but growing body of research on India's agricultural wholesale and retail markets has identified a range of developments that are increasing or could increase efficiency in the supply chains that move agricultural products from producers to consumers. Vertical integration,² led by the private sector, has significantly reduced marketing costs, reduced consumer prices, increased grower returns, and stimulated growth in India's broiler industry (Landes et al., 2004). Reducing the government's role in marketing wheat by fully decentralizing and privatizing procurement for government distribution programs could reduce producer wholesale markups for wheat, as well as sharply lower budgetary costs (Jha et al., 2007). Deregulating oilseed marketing and processing, which would allow the import of oilseeds, could improve efficiency in India's oilseed-processing industry and reduce consumer prices of edible oil while maintaining incentives for oilseed producers (Persaud and Landes, 2006; World Bank, 1997). Joseph et al. (2008) have recommended a package of reforms needed to improve the competitiveness and efficiency of India's agricultural supply chains, including the promotion of retailer cooperatives and associations to procure directly from farmers, developing professional standards and product branding, improving credit and banking services, and simplifying regulatory and licensing requirements in the marketing chain.

¹A bound tariff is the maximum tariff rate allowed by the World Trade Organization. An applied tariff is the actual tariff rate in effect at a country's border.

²One business controls or owns different aspects of buying, processing, selling, and delivering products and services.

The widespread underinvestment and inefficiency in India's agricultural marketing system, coupled with the high priority given to boosting agricultural growth, makes it important to explore the potential impacts of improvements in marketing efficiency that may occur as a result of reduced regulation and increased investment in domestic markets. This study reviews and builds on industry studies of agricultural marketing efficiency to provide an economywide assessment of the impacts of potential increases in marketing efficiency. The analysis uses a computable general equilibrium (CGE) model to estimate the effects of increased agricultural marketing efficiency on economywide production, consumption, prices, and welfare. Because the equity implications of policy reform are a key consideration for Indian policymakers, the framework also accounts for the distribution of impacts on 10 representative household types classified by rural and urban location and by income class. The impacts of increased marketing efficiency are then contrasted with those for two controversial and more commonly addressed areas of agricultural reform: liberalization of agricultural trade and removal of agricultural input subsidies.

The results indicate that, when marketing costs are reduced, impacts include higher agricultural producer prices, lower consumer food prices, and increased real consumption for all households—high and low income, rural and urban. Increasing the efficiency of agricultural marketing tends to have greater positive impacts on consumers and producers—particularly on lower income households—than do other more “traditional” reforms, such as reducing agricultural input subsidies or removing barriers to agricultural trade. A key implication is that measures to improve marketing efficiency offer a potentially valuable complement to agricultural subsidy and trade reforms.

Agricultural Policy, Investment, and Marketing Efficiency in India

Marketing services are the wholesale and retail trade services used to bring domestically produced goods from the producer to the point of sale for intermediate and final demand. In India's agricultural and food markets, the marketing chain typically consists of a primary market where farmers sell their product, wholesale markets where wholesalers who purchase from primary markets sell to processors and retailers, and retail markets where retailers sell to consumers. In many cases, additional intermediaries may be present in supply chains, including village collectors who purchase from farmers and sell in primary markets or subwholesalers who operate between wholesalers and retailers. Many, if not most, of the intermediaries in India's agricultural supply chains are small-scale, nonintegrated marketing enterprises operating in the "unorganized" sector, for which little official data are available.

Inefficient marketing systems tax producers by placing downward pressure on farm gate prices and tax consumers by raising retail prices, thus representing a potentially important target for reform. In India, agriculture accounts for about 18 percent of gross domestic product (GDP) and 58 percent of employment, and food accounts for about 47 percent of consumer expenditure (Reserve Bank of India, 2007; Government of India, Ministry of Statistics and Programme Implementation, 2005, 2008). Thus, in India, like other developing countries, the economywide impacts of improved marketing efficiency on food demand, output, and trade are potentially larger than in more developed countries where agriculture and food account for smaller shares of the economy. Improved performance of agricultural marketing may also have desirable equity outcomes by reducing food costs for low-income rural and urban consumers, who tend to allocate the largest budget shares for food.

The significance of high marketing costs as a tax on farm output is evident in studies that have quantified government intervention in Indian agriculture, in which the combination of trade restrictions and high marketing costs often result in producer prices below import parity prices for many of India's major farm commodities (U.S. Department of Agriculture, 1994; Mullen et al., 2005). There is also strong evidence that an array of central and state government policies have tended to undermine incentives for private investment by farmers and agribusinesses. These policies may have contributed to an inefficient marketing system characterized by small-scale, nonintegrated marketing service enterprises (Landes, 2008; World Bank, 1999, 1997). These policy measures include the following:

- *Movement, storage, and pricing restrictions on food commodities.* The Essential Commodities Act allows central and state governments to administratively impose movement, storage, pricing, and quality restrictions on most food commodities. These restrictions are a major source of policy risk for agribusiness investment, particularly in larger scale firms that hold relatively large stocks or operate across state borders.

- *Agricultural marketing restrictions.* State agricultural marketing laws have historically required all farm produce to be sold in government-regulated markets and prohibited private investment in markets and vertical coordination or integration between agribusinesses and farmers. These rules are now in the process of reform but with full implementation in just a few states. Government-regulated markets continue to dominate agricultural marketing in most of the country.
- *Land tenure policies.* In addition to ceilings on land ownership, many states either prohibit farm land rental or provide insufficient legal protections to either party to a rental agreement to support an active rental market. These policies impede formation of larger operational holdings and farmer access to investment credit and complicate vertical coordination between growers, processors, and traders.
- *Scale limitations on agricultural processing firms.* Until the late 1990s, most agricultural processors were required to be “small-scale industries,” restricted to fixed capital assets of no more than 10 million rupees (Rs) (about \$247,000). Although most scale restrictions have been removed, agricultural marketing and processing remain dominated by small-scale firms.
- *Credit policies.* The high cost and limited availability of credit likely restricted new investment in agriculture and agribusiness during the 1990s. Terms and availability for institutional credit have improved significantly since 2000, but a large share of farmers and agribusinesses still depend on high-cost credit from traditional moneylenders.
- *Tax policies.* Until 2000, high excise tax rates of 8-16 percent on most processed agricultural products raised costs and deterred investment in food processing. These tax rates have been reduced sharply since 2001.

This policy environment, although changing since the late 1990s, has continued to be unfriendly to private investment in agricultural marketing and processing firms, particularly larger, integrated agribusinesses, and has corresponded with sluggish investment in Indian agriculture and agribusiness. During 2003-05, the share of investment in India’s GDP was 27 percent for the economy as a whole. The share of agricultural investment in agricultural GDP was just 6 percent for investment in production agriculture and 15 percent for investment in production agriculture and agricultural marketing infrastructure (fig. 1).³ Further, while total investment in the Indian economy has been accelerating and grew about 6.5 percent annually in real terms during 1997-2004, investment in agriculture has been slowing and grew just 2.2 percent annually during the same period. Additional evidence of the low levels of investment in Indian agribusiness includes the following:

- Although more than 90 percent of India’s food grains receive primary processing, mostly in medium- or small-scale mills, relatively small shares of other food products are processed. About 2.2 percent of fruit and vegetable production receives any processing, about 35 percent of milk is processed (mostly as packaged fluid milk), and between 6 and 21 percent of poultry and meat is processed (U.S. Department of Agriculture, 2008).

³Intercountry comparisons are complicated by data limitations and differences in definitions. If one uses comparable broad definitions of investment in agriculture, India’s agricultural investment-to-GDP ratio of 15 percent for 2003-05 falls well below Brazil’s 48 percent. If one uses comparable narrow definitions, India’s investment-to-GDP ratio of 7 percent also falls below China’s 10 percent (Landes, 2008).

Figure 1

Gross fixed capital formation (GFCF) in India as share of gross domestic product (GDP)

¹Includes onfarm investment and off-farm investment in agriculture-related infrastructure.

²Includes only on-farm investments.

Source: Reserve Bank of India, *Handbook of Statistics on the Indian Economy*, Government of India, Ministry of Agriculture, 2003.

- The scale of most of India’s soybean-processing plants is in the range of 170 tons/day, far below the average capacity of U.S. plants (2,700 tons/day) and the even larger average capacity of new plants in Brazil and Argentina (Reca, 2003).
- Only 1-2 percent of food products are sold through modern chain retail establishments (U.S. Department of Agriculture, 2006).

The strong expansion of consumer food demand, along with improved national tax and credit conditions and implementation of agricultural marketing reform in some states, has improved the climate for investment in Indian agriculture since 2001. There is evidence of increased investment in modern food retailing by domestic and multinational firms (Landes, 2008; Reardon and Gulati, 2008). Findings from research on Indian agricultural markets indicate that these new private-sector initiatives could significantly improve marketing efficiency:

- Vertical integration in India’s broiler industry is improving efficiency in production and, particularly, marketing. Variable production costs averaged 10 percent lower and producer-to-retail marketing margins 60 percent lower in regions where vertical integration accounted for the largest shares of production (Landes et al., 2004).⁴
- Domestic markets for wheat and rice are inefficient because of large numbers of intermediaries, high physical losses, and disincentives for private investment (World Bank, 1999). The average producer-to-retail markup for unprocessed, ungraded, bulk wheat is estimated at 52 percent of the producer price in the private sector, with the producer-to-wholesale markup for the public-sector Food Corporation of India (FCI) estimated at 51 percent of the producer price (Gandhi and Koshy, 2007). Reducing the role of the FCI and increased investment by the private

⁴The marketing margin is the difference between the retail and farm price.

sector have the potential to increase marketing efficiency and reduce costs (Jha et al., 2007).

- Oilseed and product marketing costs in India are inflated because the scale, technology, and capacity utilization rates of oilseed-processing plants are well below international standards. Efficiency gains associated with deregulation of marketing and processing of India's major oilseeds have been estimated at 22-44 percent (World Bank, 1997).
- The efficiency of India's horticultural product markets is impeded by high logistical costs, produce wastage rates of 20-40 percent, and low domestic quality standards. Indian growers, on average, receive 12-15 percent of the retail price of horticultural produce, compared with 30-40 percent in the United States, despite the little value that is added in the Indian market (Matoo et al., 2007).

Potential Implications of Marketing Efficiency Gains

The relatively low levels of efficiency in India's agricultural marketing chains tax the output of Indian producers and the consumption of Indian consumers, but also offer a potential source of improved agricultural competitiveness and income growth over the longer term. Deregulation of agricultural markets, such as removal of private movement and storage restrictions, can benefit both producers and consumers by improving incentives for private investment in market infrastructure, new technology, and more efficient horizontally or vertically integrated agribusinesses. Producers stand to gain when improved marketing efficiency increases demand and prices for their products. Consumers can gain if more efficient wholesale and retail trade services reduce consumer prices.

The net effect of improvements in marketing efficiency on agricultural producer prices is, however, not clear cut. For producers, an efficiency-induced fall in the retail cost of food should increase quantity demanded and create upward pressure on producer prices. At the same time, this price increase could be offset by declines in producer prices as gains in marketing efficiency reduce the prices of intermediate agricultural inputs and therefore lower the costs of production. For consumers, purchase price declines associated with more efficient marketing could be offset by upward price pressure from increased quantity demanded, particularly if demand is highly responsive to changes in price (price-elastic demand) and/or expanding supply through production or trade is inhibited by technical or resource constraints (price-inelastic supply). Across commodity sectors, marketing efficiency gains are likely to affect prices, output, and demand differently, depending on the sectors' use of marketing services and potential for efficiency gains.

The total—or economywide—impacts of increasing the efficiency of agricultural and food marketing may be substantial in a developing country like India because the agricultural sector accounts for a large share of economic activity and food accounts for a large share of household budget expenditures. Gains in farm output associated with higher farm prices may significantly affect aggregate supply of agricultural goods as well as all other goods and services and agricultural trade. Lower food prices for consumers can lead to potentially large economywide changes in consumption expenditures for food and other goods and in household savings and investment.

In addition to the potential for important impacts on aggregate production, consumption, and investment, more efficient agricultural and food marketing services also have the potential to benefit low-income consumers in particular. The distribution of benefits across income groups depends on differences in food budget shares across low- and high-income households, whether their food basket is composed of commodities associated with more or less use of marketing services, and differences in household income sources. A relatively large number of India's poorest households are in rural areas, spend a relatively large share of income on food, and earn most of their income as either farmers or farm laborers. To the extent that improved marketing efficiency boosts farm prices and farm output, net sellers of food tend to gain. All net buyers of food tend to gain as consumer prices of food fall and labor demand and wages rise. Lower income rural and urban households, which tend to allocate the largest shares of income to food and depend on wage income, stand to benefit more from marketing efficiency gains than higher income households. However, higher income households can also benefit from more efficient food marketing because they tend to purchase more of the types of foods associated with intensive use of marketing services, such as processed or retail convenience foods.

Estimated Costs of Marketing Agricultural and Food Products

The costs of wholesale and retail marketing services are embedded in the purchase prices paid by firms for intermediate inputs, by households for private consumption, by government and investors for purchases of agricultural goods, and for exports. We use multiple sources to develop a dataset of estimated current agricultural and food marketing costs for domestic and export sales on a commodity basis.⁵ For the purpose of general equilibrium economic modeling, it is necessary to have comprehensive, internally consistent data that describe the input and output relationships of firms' technologies and the economywide flows of income and expenditures. In this case, we also require consistent data on the supply and demand for wholesale and retail trade services for major agricultural products. We drew primarily on the internally consistent data on the Indian economy—including total expenditures on wholesale and retail trade services by each category of demand—from the 2001 India database (version 6) of the Global Trade Analysis Project (GTAP).⁶

In the GTAP data, as in the Indian national accounts on which they are based, purchasers' expenditures on each good are reported net of marketing costs and only total trade marketing service expenditures are reported for each category of demand (intermediate, households, government, investment, and exports). These trade service data cover the full range of marketing formats in both urban and rural areas. They include the public sector's role in marketing some food products; the small, private, "organized" sector composed of relatively large-scale retail outlets, such as supermarkets; and the marketing services provided by India's large, private "unorganized" trading sector composed of myriad small shops, stalls, open markets, and bazaars (Government of India, Ministry of Statistics and Programme Implementation, 2000, 2007). Note that, within the dataset, private-own-consumption of agricultural goods—which accounts for the largest share of the goods produced and consumed by Indian farm households—is assumed to have no associated marketing costs. India has many small farmers—about 81 percent of all operational holdings, accounting for about 39 percent all farmland, are 2 hectares or less—and home consumption is estimated to account for significant shares of total use of most crops (Government of India, Ministry of Agriculture, 2008).

To disaggregate total expenditures on marketing services by each purchaser into marketing margins paid for each commodity, we relied on a combination of judgment and findings from recent studies of India's food grain, oilseed, poultry, and horticultural product markets. A major inconsistency had to be reconciled, however, between the data on total expenditures on marketing services reported in the GTAP data (and the Indian national accounts) and the much larger expenditures on marketing margins reported in the commodity market studies. One reason for the inconsistency is that the Indian national accounts data implicitly average in the zero margins for on-farm consumption—goods that do not enter the marketplace. A second reason may be the inaccuracy of the marketing cost data from the various marketing studies that are often based on available data for a few markets or regions that may not represent national average data. A third reason could be a possible tendency

⁵Author calculations to develop estimated marketing margins are described in further detail in Appendix 1.

⁶GTAP database development for each country or region combines current international data on trade flows, applied tariffs, agricultural subsidies, macroeconomic indicators, and energy use with contributed national input-output tables to create a balanced, internally consistent global database for a specified base year. The GTAP v6 database used in this study incorporates India's 1993-94 national input-output table contributed by Chadha and Pratap (2006) in a balanced global database for 2001.

for the Indian national accounts data to undercount the expenditures of trade services provided by small, rural and urban, unorganized sector firms that market most agricultural products in India.

The discrepancy in the size of marketing margins between the available sources is too large to be accommodated in the model database without a significant revision of the Indian input-output tables, which would in turn necessitate introducing numerous new assumptions and sources of error. Therefore, the approach used is to maintain the internal consistency of the model database but, to the extent possible, allocate the expenditures on agricultural marketing services to various commodity sectors in a manner that reflects the relative sizes of margins found in the marketing studies.

The data on marketing margins developed from various market studies, along with the margins used for economywide model analysis, are provided in table 1. Also reported (in the final two columns of table 1) are estimates of

²ERS estimates.

³Government of India, Ministry of Agriculture, 2008 Agricultural Statistics at a Glance; ERS estimates.

⁴Model estimates include the portions of the study-based commodity-specific estimates that are consistent with the trade service expenditure data included in India's national input-output accounts and the Global Trade Analysis Project (GTAP) database. In most cases, the expenditures implied by the marketing cost studies exceed the corresponding trade service totals in the GTAP input-output accounts and have to be scaled down to maintain consistency with the input-output accounts.

conversion factors and marketable surplus ratios used to adjust the market study data for processing and on-farm consumption. For all commodities, the marketing margins that are consistent with the findings of various market studies were scaled down to meet the constrained totals in the balanced economywide database. Margins are estimated separately for domestic sales and exports. Overall, the estimates for the domestic commodity marketing margins used in this analysis—constrained by the level of total market service expenditures in Indian national accounts—average about 21 percent of those based on the findings of commodity market studies. The estimated marketing margins for export sales, scaled to the control total in the model database, are smaller than those for domestic sales and reflect that marketing margins for export sales do not span the full farm-to-retail supply chain. Because of the downward scaling, the model data may understate the size of India’s actual agricultural marketing margins and the impacts of improved marketing efficiency.

The marketing margin estimates are marketing services costs as a percentage of the retail price. Estimated margins are relatively low for primary agricultural products, such as rice and wheat, which are often consumed on farm and often minimally processed (fig. 2). Estimated marketing margins for domestic sales are highest for dairy, fresh fruits and vegetables, processed foods, and sugar. The export margins are highest for fresh fruits and vegetables, other processed foods, pulses, and crops not elsewhere classified.⁷

Although the available data provide a basis for differentiating marketing margins across the commodity sectors, they do not permit differentiating marketing costs and margins for the various categories of consumers, such as rural or urban location and high- or low-income. We, therefore, assume a uniform marketing margin across domestic demand categories for each commodity. As a result, to the extent that urban and/or higher income consumers tend to purchase relatively more marketing services, the data may understate those expenditures. Similarly, to the extent that low-income and/or rural consumers tend to buy fewer marketing services, the data may overstate their expenditures.

⁷See appendix 1 for more detail on how these marketing costs by commodity were estimated.

Household Income and Expenditure Patterns

In the context of the recent poor performance of India’s rural sector and the implications for poverty reduction, policymakers are likely to be particularly concerned about how various types of households, particularly rural and low-income households, are likely to gain or lose from a policy change. The distribution of outcomes across households is determined by the diversity in their sources of income and by the composition of their spending. To explore the impacts of marketing efficiency gains across households, we use a database developed by Saluja and Yadav (2006) to disaggregate the GTAP data—which describe a single aggregate household—into multiple households defined by rural or urban location and by income class. The Saluja and Yadav database describes 10 household types in India, 5 urban (U) and 5 rural (R), each with 5 expenditure classes: abject poverty (R1, U1); poverty (R2, U2); middle income (R3, U3); upper income (R4, U4); and high income (R5, U5). We use the income classes defined by Saluja and Yadav to disaggregate the single aggregate household in the GTAP data to the same 10 household types.⁸

In the model database, expenditures on food, comprised of primary agricultural products and processed foods and their related marketing margins, account for 47 percent of India’s private consumption expenditures on goods and services (excluding expenditures on savings and taxes). In general—and as expected in a developing country like India—food accounts for a larger share of expenditure by rural households than by urban households, and poorer households spend proportionately more on food than do wealthier households, in both rural and urban areas (fig. 3). Also as expected, the composition of food expenditures varies across income. In general, poor households consume more whole grains and other unprocessed agricultural products than do high-income households. At higher incomes, households consume more dairy, poultry, and other processed foods, as opposed to primary agricultural products (fig. 4).

⁸See appendix 1 for a detailed discussion of how the household data were disaggregated.

Figure 3

Source: Saluja and Yadav, 2006; Global Trade Analysis Project Version 6 database.

Marketing costs for agricultural and food products in India account for a substantial proportion of household expenditures—about 5 percent of total Indian household spending on all goods and services. For all households, expenditures on marketing services are about 11 percent of the food budget. Across households, the share of total household expenditures on food marketing services tends to fall as household incomes rise, a pattern that reflects the declining share of food expenditures in the household budget as incomes rise (fig. 5). Within the food expenditure basket, however, the share of spending on marketing services rises as household incomes rise (fig. 6).⁹ This pattern reflects the shift toward consuming goods with higher marketing costs as household incomes rise. Lower income households, in contrast, tend

⁹The exception to this pattern is the highest income urban households (U5), where the share of household food expenditures spent on food marketing services is relatively low. The likely explanation is that these, generally larger, households purchase relatively large amounts of food that require little processing or other marketing services, perhaps to meet the requirements of large extended families and/or household servants.

to consume unprocessed agricultural products with relatively low marketing costs.

Indian households also differ in their sources of income—returns from land, labor, and capital. Wages are the more important income source for poorer households in India, with the role of capital and land-based earnings rising with income (fig. 7). Any changes in wage incomes are therefore likely to have the most impact on lower income rural and urban households, whereas changes in returns to capital—and to land—will be felt mostly by higher income households.

Figure 6
Food marketing costs in India as share of household food consumption expenditures by household type

Household savings and tax rates differ substantially across Indian households. Savings rates are either negative or negligible in lower income rural and urban households but rise with income: The highest income rural (R5) and urban households (U5) save 33 percent and 23 percent of their respective after-tax incomes (fig. 8). Tax expenditures are relatively low for all Indians but tend to be highest in middle-income rural and urban households.

Impacts of Potential Marketing Efficiency Gains

The analytical framework used in this study is a single-country, computable general equilibrium (CGE) model developed by the International Food Policy Research Institute (Löfgren et al., 2002). The model explicitly accounts for marketing margins as a fixed input-output quantity ratio between wholesale and retail marketing services and the sale of domestically produced food and agricultural goods in domestic and export markets. The purchase price for food and agricultural commodities in domestic and export markets is defined as the sum of the producer price plus the cost of the marketing service, plus any sales tax. Any change in the cost of marketing services directly affects the commodity purchase price, and through the demand response and changing intermediate input costs, may also affect the producer price.

The potential impacts of efficiency gains are analyzed in the model by imposing a 50-percent increase in total primary factor productivity in the production of wholesale and retail trade services used for food and agricultural commodities. This 50-percent increase implies that the same quantity of labor and capital inputs used to produce marketing services now generates 50 percent more output, thus reducing the costs of wholesale and retail marketing services. These efficiency gains are assumed to result from increased investment, improved technology, and enhanced integration in agricultural supply chains as rising consumer demand and domestic regulatory reform improve the climate for agribusiness investment and productivity growth.

We impose a relatively large increase in marketing productivity because of the evidence that the scope for efficiency gains is substantial and because the model data may understate existing marketing costs in the farm sector. The 50-percent productivity increase is equivalent to a compound annual productivity growth of about 4.5 percent over about 10 years, a timeframe compatible with a medium-run outcome in which land, labor, and capital markets fully adjust to the productivity gain. Although we expect the scope for marketing efficiency gains to vary by commodity, for simplicity—and due to lack of good detailed information by sector—we assume the same productivity gain across all food and agricultural commodities. A 50-percent increase in productivity may not be feasible in all sectors, but the anecdotal information derived from studies of India's food grain, oilseed, poultry, and fruit and vegetable industries suggests that it is a plausible overall average.

Economywide Impacts

The assumed improvement in marketing efficiency raises real GDP by 1 percent, reflecting the increased productivity of India's fixed aggregate factor supplies in providing marketing services (table 2). The scenario also generates a 1.4-percent increase in real household consumption—a welfare indicator that accounts for changes in the quantities of household consumption valued at base period prices. Additionally, improved marketing efficiency generates increases in investment that could increase future economywide output and consumption, although these dynamic impacts are not captured in the model. At the economywide level, the scenario has a small but positive impact on the producer price index, but implications for prices become more important when the focus shifts to the agricultural commodity sectors.

Table 2

Aggregate impacts of efficiency gains in agricultural and food marketing in India

Variable	50% increase in total factor productivity in agricultural and food marketing
Percent change from base	
Real gross domestic product	1.0
Real household consumption	1.4

Wages	1.6
Capital rents	0.1
Exports	0.7
Agricultural exports	3.9
Imports	0.7
Agricultural imports	-0.9
Exchange rate - rupees/U.S. dollar	0.7

Source: ERS model results.

Other economywide impacts include more government tax revenues associated with increased GDP and a small increase in the aggregate demand for imports (although demand for agricultural imports falls). Import growth leads to a small depreciation of the real exchange rate and an increase in aggregate exports. Wages and rental rates for land and capital increase in the scenario, driven by higher factor demand and the model assumption that labor and the other primary factors are fully employed. In the India case, however, labor unemployment and underemployment are substantial. Therefore, an alternative interpretation of the labor market result is that the upward pressure on wages in the labor market could increase employment and/or reduce underemployment instead of increasing wages. In this event, the increase in GDP would be even larger as more of India's productive factors are put to use.

Agricultural Sector Impacts

Increased efficiency in wholesale and retail marketing of agricultural and food products significantly affects producer and sales prices of domestic agricultural and food products (table 3). The reduction in marketing costs between producers and consumers reduces consumer prices and raises demand for most agricultural and food products. Greater demand increases production and producer prices for most agricultural and food products; the gains in marketing efficiency, therefore, are shared between producers and consumers. The largest production gains tend to be in such categories as oilseeds and products, sugar, dairy, and processed products (food, not elsewhere classified), which mostly have relatively high marketing costs (fig. 9).

Table 3

Price effects of efficiency gains in agricultural and food marketing in India

Figure 9

Production impacts of agricultural and food marketing efficiency gains in India

Percent change from base

nec = Not elsewhere classified.

Source: ERS model results.

The rise in farm output associated with marketing efficiency gains further increases India's normally substantial positive agricultural trade balance. Agricultural exports, which include a broad array of grain, oilseed, horticultural, and animal products, rise about 4 percent, whereas imports—dominated by edible oils and pulses—fall about 1 percent. Note that these results for trade, as well as for other variables, account only for medium-term adjustments to greater marketing efficiency and not for the longer term impacts of higher, sustained economic growth on food demand and trade.

Household Impacts: Income and Rural/Urban Distribution

How the impacts are distributed across households hinges on how price changes affect the costs of the bundles of goods and services purchased by households and how changes in returns to land, labor, and capital affect earnings by rural and urban households at different income levels. The results indicate that all households benefit from marketing efficiency gains, which reduce consumer prices of most food items. Lower income households benefit primarily because they allocate a larger share of their expenditures to food (fig. 10). Higher income households also benefit because they tend to spend more than lower income households on foods, such as dairy products, that use larger amounts of marketing services.

Income gains tend to favor rural households and poor households in both urban and rural areas because wages rise more than do returns to capital. And, for rural households—whether low- or high-income—higher earnings are driven by increased returns to land associated with higher farm output.

The gains to rural households may be overstated and the gains to urban households understated by the model because the underlying data on marketing margins are an average of on-farm consumption, which does not incur marketing costs, and marketed consumption, which does incur marketing costs. To the extent that lower income rural—but not urban—households spend less than the average marketing costs on goods in their expenditure baskets, their estimated gains are overstated. Similarly, the impacts on higher income households, both rural and urban, are understated to the extent that they purchase products with higher-than-average marketing costs for a given product category. Although it is important to realize these potential biases in the results, the size of the estimated gains for both rural and urban low-income households suggests that the gains would remain substantial even if these data deficiencies could be corrected.

Comparing the Impacts of Increased Marketing Efficiency With Agricultural Input Subsidy and Tariff Reform

Reform of India's agricultural subsidy and tariff policies have been topics of debate by Indian policymakers and trade partners since at least the early 1990s. Rising input subsidy outlays are often criticized for causing factor market distortions and diverting public resources from productive investments, but they have been sustained and even enlarged because of concerns for the welfare of India's many small-scale farmers. India's high agricultural tariffs are challenged in the current multilateral negotiations and elsewhere for imposing high costs on consumers and hindering longer term competitiveness, but liberalizing reforms are also strongly resisted largely because of concerns with farmer welfare.

The goal of comparing subsidy and tariff reform with increased agricultural and food marketing efficiency is to assess and compare their effects on the economy, commodity sectors, and households. These broad areas of agricultural policy reform offer a general representation of the policies that might be adopted in India, but they are not necessarily comparable in terms of the magnitude of their impacts.

India's Agricultural Subsidies

The cost of India's major agricultural input subsidies for electrical power, fertilizer, and irrigation water has grown about 6 percent annually in real terms since 1990, reaching nearly Rs500 billion (about \$10 billion) in 2002/03 (fig. 11) (Mullen et al., 2005; Gulati and Narayanan, 2003). The cost of providing free or subsidized (depending on the state) electricity for agriculture accounts for more than two-thirds of total input subsidies, as well as most of the growth since 1990. Irrigation is a key factor in boosting crop yields, but the policy of subsidizing electricity is also now widely acknowledged to be promoting inefficiency in water use and overpumping of groundwater. Fertilizer subsidies are provided to farmers in the form of price subsidies for domestic and imported fertilizers and to the fertilizer industry in the form of preferential prices to offset the losses of higher cost plants. For this study, we include only subsidies going to farmers, which amounted to about Rs70 billion (\$1.4 billion) in 2002/03 and have tended to decline since the mid-1990s. Subsidies for canal irrigation water were about Rs60 billion (\$1.2 billion) in 2002/03 but have shown little growth.

The rising outlays for input subsidies, which were equivalent to about 11 percent of total agricultural output in 2002/03, are of growing concern for Indian policymakers. By comparison, public investment in agriculture and agricultural infrastructure amounted to just 5 percent of agricultural GDP in 1999-2000 (the most recent period available) and has shown relatively sluggish real annual growth of less than 1 percent since 1990. Although reform of India's subsidy policies would potentially make available more public resources for productive investments in irrigation, research, market services, and infrastructure, withdrawing the subsidies has proven difficult because of their popularity with rural voters and, in the case of power and water subsidies, the state governments that administer them.

Figure 11

Major Indian agricultural input subsidies, 2001

Source: Global Trade Analysis Project Version 6 database; author calculations.

The Government of India has also been incurring substantial and rising budgetary costs for operating the system of minimum support prices (MSPs), public distribution, and storage for wheat and rice. The real cost of what is called the “food grain subsidy” has climbed steadily since the late 1990s, reaching an average of Rs242 billion (\$5.5 billion) during 2004/05-2006/07 (Government of India, Ministry of Finance, 2008). Rising costs have stemmed from increased government procurement and storage costs associated with defending higher support prices and with introducing new and more highly subsidized distribution programs for poor and disadvantaged groups.

Despite these substantial and rising costs, the food grain subsidy is not specifically included in the data and subsidy-reduction scenario used in this study for two reasons. First, the system of supporting MSPs is combined with border policies, such as export restrictions, and domestic measures, such as levies on rice millers and grain movement restrictions, that can also tax producers. Calculations of producer subsidy equivalents (U.S. Department of Agriculture, 1994) and producer support estimates (Mullen et al., 2005) that incorporate careful comparisons of world prices and Indian domestic prices show that these policies net out as subsidies in some years and taxes in others. According to this evidence, there is no clear rationale for characterizing the bundle of expenditures and policies called the food grain subsidy as a subsidy (or tax) on producers. Second, India’s domestic marketing costs are an important factor in assessing levels of market price support, and the impacts of these costs are already being studied separately.

India’s Agricultural Tariffs

India completed the elimination of quantitative restrictions on agricultural imports in 2001 but maintains relatively high bound tariffs on most agricultural commodities (fig. 12). Reductions in India’s agricultural tariffs have

Figure 12

Indian applied agricultural import tariffs, 2001

Percent ad valorem

nec = Not elsewhere classified.

Source: Global Trade Analysis Project Version 6 database.

been an important target of the United States and other trading partners in bilateral and multilateral settings, including the current Doha Round.

India remains reluctant to commit to reducing bound agricultural tariffs that afford protection to its large number of small-scale farmers and agribusinesses. However, the government has made unilateral reductions in applied rates to facilitate imports and contribute to increased price stability for commodities in short supply, including pulses, vegetable oils, and, most recently, wheat (Landes, 2008). There is evidence that reductions in at least some currently prohibitive tariffs could yield a significant boost to industries, such as oilseed processing, that lack access to raw materials and to producers who are now isolated from world market prices (Persaud and Landes, 2006). However, in a number of cases, such as rice, oil meals, fruits and vegetables, and poultry meat, India has high applied tariffs on goods for which domestic prices are typically competitive in regional or global markets in order to assure adequate protection and bargaining strength with trading partners. In these cases, tariff reductions would have little or no impact on import demand. The model addresses the impacts of tariff changes by treating imported and exported products separately from domestic goods, thus limiting the impact of tariff reductions on the Indian goods, which, despite high tariffs, tend to have relatively low internal prices and import demand.

Recent studies by Ganesh-Kumar et al. (2006) and Polaski et al. (2008) of the potential impacts of agricultural trade liberalization on the agricultural sector as a whole have indicated that, in the short run, the benefits to India from participating in a global agricultural reform agenda would be positive but modest. Polaski et al. stress the importance of setting negotiating terms that balance the interests of India’s poor households with the benefits of improved efficiency and market opportunities.

Scenario Comparisons

The subsidy reform scenario simulates removal of all agricultural input subsidies, and the tariff reform scenario simulates the removal of all agricultural tariffs. Because the effects of the subsidy and tariff reform scenarios and the increased marketing efficiency scenarios are not necessarily comparable in terms of magnitude, our discussion focuses on the patterns of their effects on the economy and across commodities and households.

The removal of agricultural input subsidies leads to a relatively small increase in real GDP (fig. 13), but higher producer and consumer prices for staple food commodities, particularly for grains and fibers, which receive the bulk of input subsidies (figs. 14 and 15), cause aggregate real household consumption to fall.¹⁰ Producer and consumer prices of nonsubsidized commodities fall because of an overall decline in consumer expenditures and a shift in land use away from crops that lose subsidies.

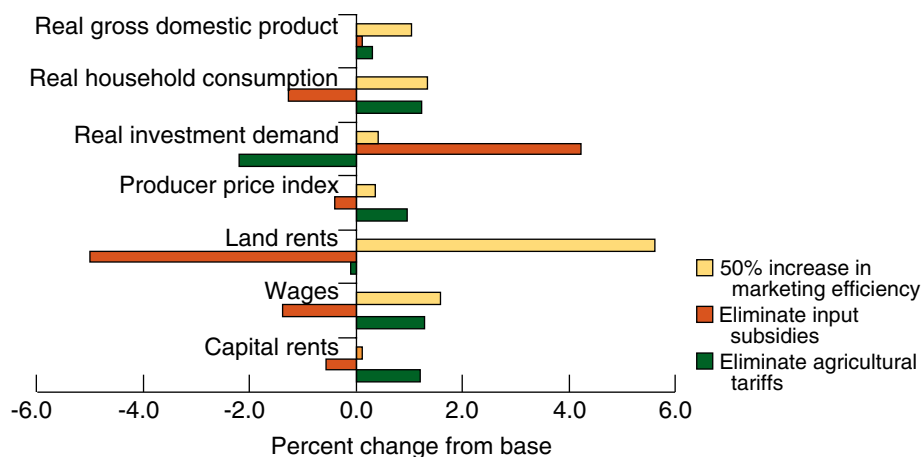

The decline in agricultural production reduces agricultural employment and economywide wages. However, the substantial government savings from eliminating subsidies boost national savings and investment, thus improving prospects for future growth in output, employment, and consumption—dynamic effects that are not accounted for in our static framework. With lower factor returns and higher prices for food staples (wheat and rice), at least in the near term, real consumption declines for all household types (fig. 16). Consumption losses are greatest in poorer and rural households, reflecting the combination of lower returns to land and labor and substantially higher prices for food staples.

When agricultural tariffs are removed, the more efficient allocation of resources leads to growth in real GDP and increases in the returns to labor and capital and in aggregate real household consumption. But, the decline in government tax revenue in this scenario causes aggregate savings and investment to fall. The removal of agricultural tariffs has minor impacts on overall producer and consumer prices and farm output, reflecting relatively

¹⁰See appendix 3 for complete numerical results from the scenarios.

competitive domestic prices and generally small amounts of trade in such sectors as food grains, fruits and vegetables, fibers, and dairy. However, more heavily protected sectors with less competitive domestic prices, including fats and oils and poultry, face potentially significant producer

Figure 16

Source: ERS model results.

price and output shocks when tariffs are removed. Higher returns to labor and capital lead to increased real consumption by all rural and urban households. Consumption gains are largest in lower income households, driven by higher wages, relatively small increases in staple food prices, and significant consumer price declines for highly protected items, particularly fats and oils.

Comparisons across the three scenarios suggest that improved agricultural and food marketing efficiency can increase returns to land and labor and significantly boost aggregate real consumption relative to the other scenarios. The magnitude and distribution of household consumption gains associated with improved marketing efficiency are similar to those in the tariff removal scenario but in sharp contrast to the potentially adverse consequences of subsidy removal, at least in the near term. Unlike the subsidy and tariff reform scenarios, improvements in marketing efficiency have the potential to provide price benefits to both producers and consumers, particularly lower income and rural households. In contrast, the results suggest that removing subsidies could substantially raise consumer prices for food staples, while lowering tariffs could substantially reduce production in currently protected sectors, such as oilseed products, poultry, and processed foods.

Finally, although the model does not account for dynamic changes in savings and investment over time, the scenarios differ substantially in their implications for economywide savings, investment, and future growth. The marketing efficiency scenario suggests modest increases in savings and investment, tariff elimination reduces savings and investment, and the removal of subsidies generates substantial gains in government savings and investment. A dynamic framework that accounts for the effects of investment on economic growth would likely indicate stronger growth benefits from improved marketing efficiency and reduced subsidies compared with that arising from the removal of trade-distorting tariffs.

Conclusions

The results suggest that measures to improve agricultural marketing efficiency in India, perhaps including strengthening public and private marketing institutions and improving the regulatory climate for private agribusiness investment, may substantially and broadly benefit India's economy. Advances in marketing efficiency are shown to have the potential not only to increase income and employment economywide, but to provide positive price impacts for both agricultural producers and consumers and benefits to all households—particularly for rural and low-income households.

In a broader sense, the results also suggest the potential for greater investment and efficiency in India's agricultural markets to be a source of enhanced agricultural growth, trade, and competitiveness over the longer term. Whether new policies lead to rapid investment by modern retailers and others in transforming markets or the process occurs gradually, the results suggest that improvements in domestic marketing efficiency, although boosting food demand, may also strengthen agricultural exports and reduce imports. However, these results neither account for changes in food and feed demand that are likely to occur as higher income growth is sustained over the longer term nor account for constraints on crop and livestock production that may emerge with increased land use intensity, yields, and feed demand.

Finally, this analysis highlights the dilemma of Indian policymakers as they face domestic and international pressures for subsidy and tariff reform. Despite any economywide benefits from subsidy and tariff reform, particularly in a more dynamic and longer term framework, these measures have the potential to create adjustment costs for some commodity sectors and households—at least in the medium term. These potential costs may make implementing subsidy and tariff reform more difficult given the large share of rural and low-income households in India. In contrast, the effects on the economy and on households of increased efficiency in agricultural marketing suggest that this approach may be a valuable complement to subsidy and tariff reforms because of the potential to help mitigate the adjustment costs associated with those measures.

The modeling framework used here does not permit full analysis of the adjustment costs that might be incurred if India's traditional marketing system were transformed into a more efficient sector. This transformation likely would lead to losses in employment and income in some traditional firms. But, there would be more, larger scale, vertically integrated, and more technologically advanced processing and marketing enterprises that would provide new employment and investment opportunities. Concerns with these adjustment costs are an important part of the current debate over whether to permit foreign direct investment in multibrand retail marketing in India (Mukherjee and Patel, 2005). The results of this study indicate that improvements in agricultural marketing efficiency that explicitly entail reduced labor and capital inputs in providing marketing services still put upward pressure on economywide returns to labor and capital. Although some participants in the traditional marketing system will undoubtedly face adjustment costs, the economywide employment and consumption impacts are shown to be positive.

For the United States, these results suggest that the process of increasing investment and efficiency in India's agricultural markets could moderate growth in India's future agricultural imports, but also act as an important driver of India's economywide income and demand growth. The results of the analysis for various commodity sectors and households indicate why domestic support and market access issues are sensitive for India in bilateral and multilateral negotiations. The results also suggest avenues for addressing these concerns through cooperation and investment, which could contribute to more efficient domestic marketing chains. Further, the gains in output and consumption associated with introducing improvements in marketing efficiency suggest the potential for returns to private investment in India's agricultural markets.

Analytical issues that would be useful to address in future work include improved data on wholesale and retail marketing costs in Indian food and agriculture, not only by commodity, but also by purchaser. Recent sector studies of India's agricultural markets conducted by the World Bank, USDA's Economic Research Service, and others indicate producer-to-retail marketing costs that are substantially higher than those implied by the available input-output data for the Indian economy used for this study. If this is true, then the current study likely underestimates the potential economywide gains from improved agricultural marketing efficiency. In addition, as noted, the use of a dynamic framework would better capture the potentially significant, long-term growth implications of marketing efficiency gains in Indian food and agriculture.

Appendix 1: Model and Database

We use the single-country, International Food Policy Research Institute (IFPRI) standard computable general equilibrium model (CGE), which explicitly describes the wholesale and retail transaction services that link production to sales and create a price wedge between producer and purchaser prices.¹¹ Production is described by a constant elasticity of substitution (CES) value-added production function with Leontief intermediate technology. Consumer demand is described by a Cobb-Douglas utility function. Three factors of production—labor, capital, and land—are fully mobile within the country and fixed in aggregate supply. India is linked to the rest of the world through trade flows that are described by Armington import demand and constant elasticity of transformation (CET) export supply functions. The model’s macroeconomic closure was chosen to realistically represent the Indian economy. Investment is savings driven, with private savings changing as household incomes change, given fixed private savings rates. Public savings (the fiscal deficit/surplus) adjust with changes in tax revenues and subsidy and transfer payments, given fixed real government expenditures and fixed tax and subsidy rates.¹² We assume a flexible exchange rate that adjusts to maintain a fixed current account balance. The consumer price index is used as numeraire. The model is implemented in the General Algebraic Modeling System (GAMS) software documented in Rosenthal (2007).

The database for the model is the Global Trade Analysis Project (GTAP) Version 6 with a base year of 2001. We use the data-download program developed by McDonald and Thierfelder (2004) to organize the GTAP data for India and its world trade flows into a 23-sector Social Accounting Matrix (SAM) that is compatible with the IFPRI standard CGE model. We develop a model database with 30 sectors, of which 12 are crop and livestock sectors in primary agriculture. Seven sectors encompass processed foods, beverages, and tobacco. The five remaining commodity sectors are natural resources, textiles, apparel, and light and heavy manufacturing. There are two trade services sectors: (1) the wholesale and retail trade services required for domestic and export sales of domestically produced agriculture and food, and (2) all other trade services in the economy. Armington and export supply elasticities have a value of 2; the factor substitution elasticities have a value of 0.8. Households’ Cobb-Douglas utility functions imply, for each good, a unitary income elasticity, a negative own-price demand elasticity of one and zero cross-price demand elasticities.

For this analysis, the GTAP SAM for India was extended in three ways: (1) commodity disaggregation, (2) trade services sector disaggregation, and (3) household disaggregation. We disaggregated three of the agricultural and processed food sectors in the GTAP database to support a more detailed analysis of several important Indian commodities: (1) corn was separated from GTAP “other grain” to create corn and other grain, (2) pulses were separated from GTAP “fruits and vegetables” to create fruits and vegetables and pulses, and (3) GTAP “oils and fats” were separated into oils and fats and oilmeals.

To disaggregate the subsectors, activity columns were added to the SAM to describe subsectors’ intermediate inputs, factor demands, and taxes. Commodity columns were added to describe subsectors’ domestic produc-

¹¹The model is fully documented in Löfgren et al., 2002.

¹²For a detailed discussion of the implications of model macroclosure rules, see Löfgren (2002) and Robinson (1991). The use of the CET function contributes to the limited response of export supply to changes in import tariffs. The use of Armington import demand functions constrains the import demand response to tariff elimination. The import response in the model to tariff reform may still be overstated in cases where domestic prices are below tariff-adjusted world prices and tariffs are not the binding constraint on imports.

tion, imports, and commodity taxes. Corresponding activity rows and commodity rows were also added. The activity rows report the sale of total domestic production of the subsectors to the commodity accounts. The commodity rows report intermediate and final demand for each new subsector. The newly disaggregated rows and columns of the SAM sum to the original rows and columns. Data used for the agricultural sector disaggregation are drawn from multiple USDA data sources.

The trade services sector in the SAM is disaggregated into (1) trade services used in wholesale and retail sales of domestically produced food and agricultural commodities to domestic and export markets, and (2) all other trade services. The objective of the disaggregation of the agricultural and food trade services sector is to create a link between total expenditures by firms and final demand (households, government, investment, and exports) on trade services reported in the GTAP database and the commodity composition of those wholesale and retail trade services. As a first step in creating this link, we create control totals for aggregate domestic and export agricultural marketing expenditures by assuming that the trade services required for all domestically consumed goods are of equal proportion and that those provided for exports are of equal proportion. The control total for trade services used for domestic sales of agricultural and food goods is then assumed to equal the share of these goods in aggregate domestic expenditure multiplied by total domestic trade service expenditure in the economy. The control total for marketing expenditures on exports of agricultural and food goods is assumed to equal the budget share of these goods in total export sales multiplied by total export trade service expenditure. Next, to capture variation in marketing costs across agricultural and food commodities, we estimate trade margin costs for each commodity by applying to the domestic and export control totals the trade and marketing margins based on farm-retail price spread data and data from various studies of Indian commodity markets. Finally, the trade service margins for domestic and export sales are uniformly scaled so that the sums of trade service expenditures are equal to the control totals for domestic and export trade service expenditures and meet the constraint that, for any production activity or agent, agricultural trade expenditures cannot exceed total trade expenditures by commodity reported in the GTAP data. For sectors in which base exports are a negligible share of production, trade and marketing costs on export sales are assumed to be zero.

The category “other trade services” becomes a residual of the trade service sector in the GTAP data. It is defined as total trade service expenditures minus trade services produced and consumed in marketing domestic production of agricultural and food goods.

We follow Arndt et al. (1999) in restructuring the India SAM to include one production activity row and one activity column to describe the production and sale of margin services used for agricultural and food products. The activity column account reports the production technology as a proportion of, and identical to, the production of trade services in the original SAM. One commodity row account and one commodity column account is added to the SAM to describe the supply of and demand for margin services used for agricultural and food products. The commodity column account describes the supply of margin services, which are only produced domestically. The commodity row account describes the intermediate input demand

for the margin service in the production of margin services and the allocation of margin services for marketing domestic sales and exports. Two trade margin accounts (a column and row for each) are added to the SAM—one for domestic sales and one for export sales. The trade margin row accounts report demand for trade margin services for the sale of agricultural and food products in the domestic market and as exports. These margins are demanded by each agricultural and food commodity, in their column accounts, so that the value of each agricultural and food commodity purchase reported in the SAM now includes its trade margin on the domestic variety. Nonfood and nonagricultural commodity purchases are reported net of marketing costs.

Expenditures by firms, households, government, investment, and exports are adjusted so that expenditures on food and agricultural commodities are reported in purchaser prices that include the wholesale and retail trade and marketing costs. These trade service expenditures, now embedded in commodity prices, are then subtracted from each agent's total expenditures on trade margin services.

Finally, we extend the India SAM by disaggregating the single household into 10 representative households. Household income and expenditure data are from the 2003/04 India SAM developed by Saluja and Yadav (2006). Using 1999-2000 data from the National Sample Survey Organization (Government of India, Ministry of Statistics and Programme Implementation, 2001), Saluja and Yadav disaggregated 10 household types that characterize 5 income and expenditure classes each for rural and urban households: abject poverty, poverty, middle income, upper income, and high income. The middle household classes have national average per capita expenditures in urban and rural areas. Saluja and Yadav draw data on sources of factor income by household type from Pradhan and Roy (2003).

The 73-sector data in the Saluja and Yadav SAM are aggregated into the sectors of the GTAP India SAM, and the household income and expenditure shares of the 10 household types are then applied to disaggregate the single household in the GTAP SAM. Because the Saluja and Yadav SAM includes only labor and capital, whereas the model used here also includes land, we assume that land income has the same distribution as capital income in the Saluja and Yadav database. Furthermore, we assume that land returns accrue only to rural households.

Appendix 2: Sector Aggregation From GTAP Database: Mapping GTAP Sata Into the India SAM

No.	Sector name	GTAP sector
1	Rice	pdr pcr
2	Wheat	wht
