January 2011

Abstract

We investigate the role of differences in TFP growth between the construction sector and the general economy in the evolution of real housing prices. We find evidence of a strong positive contribution of relative TFP to housing prices in the U.S. and Germany but not in Spain and the U.K.

JEL Classification: E01, E23, E25, E32.

Keywords: House prices, TFP, growth accounting, Cobb-Douglas.

*We would like to thank Henrique Basso, Joel Lopez-Real, Anton Nakov, and seminar participants at the Bank of Spain for the useful comments. The views expressed are those of the authors and do not represent the views of the Bank of Spain or the Eurosystem.

1 Introduction

We investigate the role of differences in TFP growth between the construction sector and the general economy in the evolution of real housing prices in four major countries. We first compare housing prices with construction prices in the U.S., the U.K., Spain and Germany. We find that housing prices closely follow construction prices during the pre-1997 period while they diverge afterwards in all countries, although to a different extent. Only in the U.S. the two prices are back to a common level in 2007.

Secondly, we use a growth-accounting framework, based on Solow (1957) and Jorgenson, Gollop and Fraumeni (1987), to assess the contribution of the TFP growth differential between the construction sector and the general economy on construction prices. Our results suggest that the surge in construction prices in the U.S. is the consequence of an increase in relative TFP growth between the general economy and the construction sector, especially since the mid-90s.¹ Relative TFP also drives construction prices in Germany. However, we find that the rise in construction prices in both the United Kingdom and Spain is not due to TFP differences but to relative rental prices of labor and capital between the construction sector and the general economy.

2 Housing Prices versus Construction Prices

Figure 1 displays construction and housing prices for the U.S., the U.K., Germany and Spain. In the U.S., housing prices track construction prices until 2001. During the “housing boom”, from 2002 to 2006, house prices rise faster than construction ones. In 2007, housing prices fall to the same level as construction prices. Overall, construction prices grow around 70% since 1987, a magnitude similar to the increase in housing prices. In the U.K. and in Spain, instead, house prices more than double in the decade 1997-2007 whereas construction prices only grow around 40%. In Germany, house prices fall more than 10% after 2003 whereas construction prices slightly grew. Thus construction prices seem to play a pivotal role in the evolution of house prices in the U.S., whereas the relationship between both prices is feebler in the other countries.

3 Growth Accounting Methodology

We assume that the production in the construction sector c and in the general economy g at time t , $Y_{i,t}$, follows a Cobb-Douglas function:

$$Y_{i,t} = A_{i,t} K_{i,t}^{\alpha_i} L_{i,t}^{1-\alpha_i}, \quad i = \{c, g\}, \quad (1)$$

where $K_{i,t}$ and $L_{i,t}$ are, respectively, the sector-wide capital and labor services and $A_{i,t}$ is total factor productivity (TFP). Capital and labor services in the two sectors are not required to be homogenous. Given (1), TFP can be computed using data on sectoral output, capital services and labor services.

With competitive markets, the price of one unit of $Y_{i,t}$ is, in equilibrium,

$$P_{i,t} = \frac{W_{i,t}^{1-\alpha_i} R_{i,t}^{\alpha_i}}{\alpha_i^{\alpha_i} (1-\alpha_i)^{1-\alpha_i}} \frac{1}{A_{i,t}}, \quad (2)$$

¹Iacoviello and Neri (2010) and Khan (2008) find a similar result in the context of dynamic general equilibrium models. For the acceleration of aggregate TFP in the U.S. see Jorgenson and Stiroth (2000).

where $R_{i,t}$ is the rental rate of capital and $W_{i,t}$ is the wage rate in sector i . Equation (2) implies that

$$\frac{(\dot{P}_{c,t}/P_{g,t})}{(P_{c,t}/P_{g,t})} = \underbrace{\alpha_c \frac{\dot{R}_{c,t}}{R_{c,t}} - \alpha_g \frac{\dot{R}_{g,t}}{R_{g,t}} + (1 - \alpha_c) \frac{\dot{W}_{c,t}}{W_{c,t}} - (1 - \alpha_g) \frac{\dot{W}_{g,t}}{W_{g,t}}}_{(a)} + \underbrace{\frac{(A_{g,t}/A_{c,t})}{(A_{g,t}/A_{c,t})}}_{(b)}. \quad (3)$$

Equation (3) allows us to decompose the growth in the relative price of construction into two components: (a) that depends on the growth in the price of capital and labor services in the two sectors weighted by the intensity of capital and labor services in production, α_c and α_g ; and (b) that depends on the TFP growth differential between the two sectors. By using (3) it is possible to separate the increase in the relative price of construction due to market conditions (changes in the prices of capital and labor) from that due to different TFP growth in the two sectors.

4 Results

The EU KLEMS database, November 2009, provides time series of $Y_{i,t}$, $K_{i,t}$, $L_{i,t}$, $P_{i,t}$, $W_{i,t}$, $R_{i,t}$ for the construction sector and the general economy for the U.S., the U.K., Germany and Spain. If the Cobb-Douglas is a good approximation of the production technology, the price of output measured in the data should be close to the theoretical price given by (2), and (3) can be used to decompose the relative price of construction.

To test whether the Cobb-Douglas assumption is supported by the data we first compute TFP $A_{i,t}$ in construction and in the general economy using data for $Y_{i,t}$, $K_{i,t}$, $L_{i,t}$ and (1). Next, by taking logarithms of (2) we obtain

$$\log(P_{i,t}) = \beta_i + \beta_{i,r} \log(R_{i,t}) + \beta_{i,w} \log(W_{i,t}) + \beta_{i,a} \log(A_{i,t}), \quad (4)$$

where $\beta_i = -\log[\alpha_i^{\alpha_i} (1 - \alpha_i)^{1 - \alpha_i}]$, $\beta_{i,r} = \alpha_i$, $\beta_{i,w} = 1 - \alpha_i$, and $\beta_{i,a} = -1$. Equation (4) can be estimated by using data on $P_{i,t}$, $W_{i,t}$, $R_{i,t}$ and the series of $A_{i,t}$. If the estimated coefficients are statistically significant and close to their theoretical counterparts, then the Cobb-Douglas function represents a good approximation of the production technology. This is true because all series $Y_{i,t}$, $K_{i,t}$, $L_{i,t}$, $P_{i,t}$, $W_{i,t}$, $R_{i,t}$ in the EU KLEMS dataset are not constructed subject to the Cobb-Douglas assumption.

Table 1 reports the results of estimates of regressions based on (4) for both construction and the general economy.² All estimated coefficients are close to their theoretical values and statistically significant.³ We also run an F -test for constant returns to scale in production and find that the null hypothesis cannot be rejected at 1% significance level in all estimations apart from the German general economy. Figure 2 reports the relative price of construction measured in the data (solid blue line) and the theoretical one (circle blue line) constructed using EU KLEMS data and the right hand side of (3). The two series almost perfectly overlap in the graph for all countries.

Finally, we use (3) to decompose the growth in the relative price of construction. Results appear in table 2. For each country, the first three rows report the average yearly growth rate of the relative price P_C/P_G , of relative TFP A_G/A_C and of relative rentals $(R_C^{\alpha_C} W_C^{1 - \alpha_C}) / (R_G^{\alpha_G} W_G^{1 - \alpha_G})$

²Equation (2) implies a stable relationship among the variables $P_{i,t}$, $W_{i,t}$, $R_{i,t}$, and $A_{i,t}$. This implies that the corresponding time series in the data should be cointegrated. Although we do not perform a complete cointegration analysis, we test the stationarity of the residual series of each regression using the Augmented Dickey Fuller test. The residual series are stationary in each regression.

³All price series are normalized to one in the first period, so that $\beta_c = \beta_g = 0$.

while the fourth and the fifth rows report the contribution of relative TFP and relative rentals to the growth of P_C/P_G , for four subperiods.⁴

In the U.S., 95% of the increase in the relative price of construction during the 1980-2007 period is explained by the increase in relative TFP. In particular, the acceleration of TFP growth in the general economy occurred in the nineties is responsible for the steep increase in relative TFP measured in the last part of the sample. In the U.K. instead, changes in relative TFP contribute negatively to the relative price of construction, which increased due to the rise in relative rentals. The case of Germany is similar to the U.S.. Relative TFP growth accounts for 125% of the growth in the relative price of construction. Finally, in Spain, relative TFP is not responsible for the increase in the relative price of construction during the 1980-2007 period. During the 1998-2007 period, characterized by large increases in housing prices in most countries, relative TFP displays a positive contribution to the growth in the relative price of construction in all countries: in the U.S. relative TFP explains all of the increase in the relative price of construction, in the U.K. 23%, in Germany 93% and in Spain 32%. To conclude, figure 2 reports relative TFP and relative rentals in all countries.

5 Conclusions

We have shown that technological differences between the general economy and the construction sector can account for the evolution of housing prices in the U.S. In the U.K. and Spain, instead, the evolution of construction prices and technological factors accounts for a small part of the surge in housing prices in the last decade. We conclude that, although the timing of the steep increase in housing prices is similar in all countries, the driving forces of this surge are different across countries.

⁴The sum of contributions might not sum to 100% due to large growth rates.
