ECONOMETRIC INSTITUTE REPORT 2008-17

This version: August 2008

Abstract: This short note presents the R package AdMit which provides flexible functions to approximate a certain target distribution and it provides an efficient sample of random draws from it, given only a kernel of the target density function. The estimation procedure is fully automatic and thus avoids the time-consuming and difficult task of tuning a sampling algorithm. To illustrate the use of the package, we apply the AdMit methodology to a bivariate bimodal distribution. We describe the use of the functions provided by the package and document the ability and relevance of the methodology to reproduce the shape of non-elliptical distributions.

Keywords: adaptive mixture, Student-*t* distributions, importance sampling, independence chain Metropolis-Hasting algorithm, Bayesian, R software

AdMit

A package for constructing and using an adaptive mixture of Student-*t* distributions as a flexible candidate distribution for efficient simulation.

by David Ardia, Lennart F. Hoogerheide and Herman K. van Dijk

Introduction

This note presents the package AdMit (Ardia et al., 2008a,b), an R implementation of the adaptive mixture of Student-t distributions (AdMit) procedure developed by Hoogerheide (2006); see also Hoogerheide et al. (2007); Hoogerheide and van Dijk (2008) for details. The AdMit strategy consists of the construction of a mixture of Student-t distributions which approximates a target distribution of interest. The fitting procedure relies only on a kernel of the target density, so that the normalizing constant is not required. In a second step, this approximation is used as an importance function in importance sampling or as a candidate density in the independence chain Metropolis-Hastings (M-H) algorithm to estimate characteristics of the target density. The estimation procedure is fully automatic and thus avoids the difficult task, especially for non-experts, of tuning a sampling algorithm. Typically, the target is a posterior distribution in a Bayesian analysis, where we indeed often only know a kernel of the posterior density.

In a standard case of importance sampling or the independence chain M-H algorithm, the candidate density is unimodal. If the target distribution is multimodal then some draws may have huge weights in the importance sampling approach and a second mode may be completely missed in the M-H strategy. As a consequence, the convergence behavior of these Monte Carlo integration methods is rather uncertain. Thus, an important problem is the choice of the importance or candidate density, especially when little is known a priori about the shape of the target density. For both importance sampling and the independence chain M-H, it holds that the candidate density should be *close* to the target density, and it is especially important that the tails of the candidate should not be thinner than those of the target.

Hoogerheide (2006) and Hoogerheide et al. (2007) mention several reasons why mixtures of Student-*t* distributions are natural candidate densities. First, they can provide an accurate approximation to a wide variety of target densities, with substantial skewness and high kurtosis. Furthermore, they can deal with multi-modality and with non-elliptical shapes due to asymptotes. Second, this approximation can be constructed in a quick, iterative procedure and a mixture of Student-*t* distributions is easy to sample from. Third, the Student-*t* distribution has fatter tails than the Normal distribution; especially if one specifies Student-*t* distributions with few degrees of freedom, the risk is small that the tails of the candidate are thinner than those of the target distribution. Finally, Zeevi and Meir (1997) showed that under certain conditions any density function may be approximated to arbitrary accuracy by a convex combination of *basis* densities; the mixture of Student-*t* distributions falls within their framework.

The package **AdMit** consists of three main functions: AdMit, AdMitIS and AdMitMH. The first one allows the user to fit a mixture of Student-*t* distributions to a given density through its kernel function. The next two functions perform importance sampling and independence chain M-H sampling using the fitted mixture estimated by AdMit as the importance or candidate density, respectively.

To illustrate the use of the package, we apply the AdMit methodology to a bivariate bimodal distribution. We describe the use of the functions provided by the package and document the ability and relevance of the methodology to reproduce the shape of non-elliptical distributions.

Illustration

This section presents the functions provided by the package **AdMit** with an illustration of a bivariate bimodal distribution. This distribution belongs to the class of conditionally Normal distributions proposed by Gelman and Meng (1991) with the property that the joint density is not Normal. It is not a posterior distribution, but it is chosen because it is a simple distribution with non-elliptical shapes so that it allows for an easy illustration of the AdMit approach.

Let X_1 and X_2 be two random variables, for which X_1 is Normally distributed given X_2 and vice versa. Then, the joint distribution, after location and scale transformations in each variable, can be written as (see Gelman and Meng, 1991):

$$p(\mathbf{x}) \propto k(\mathbf{x}) \doteq \exp\left[-\frac{1}{2}(Ax_1^2x_2 + x_1^2 + x_2^2) - 2Bx_1x_2 - 2C_1x_1 - 2C_2x_2)\right]$$
(1)

where $p(\mathbf{x})$ denotes a density, $k(\mathbf{x})$ a kernel and $\mathbf{x} \doteq (x_1, x_2)'$ for notational purposes. *A*, *B*, *C*₁ and *C*₂ are constants; we consider an asymmetric case in which A = 5, B = 5, $C_1 = 3$, $C_2 = 3.5$ in what follows.

The adaptive mixture approach determines the number of mixture components *H*, the mixing probabilities, the modes and scale matrices of the components in such a way that the mixture density approximates the target density $p(\mathbf{x})$ of which we only know a kernel function $k(\mathbf{x})$ with $\mathbf{x} \in \mathbb{R}^d$. Typically,

 $k(\mathbf{x})$ will be a posterior density kernel for a vector of model parameters \mathbf{x} . The AdMit strategy consists of the following steps:

- (0) Initialization: computation of the mode and scale matrix of the first component, and drawing a sample from this Student-*t* distribution;
- Iterate on the number of components: add a new component that covers a part of the space of x where the previous mixture density was relatively small, as compared to k(x);
- (2) Optimization of the mixing probabilities;
- (3) Drawing a sample from the new mixture;
- (4) Evaluation of importance sampling weights: if the coefficient of variation, the standard deviation divided by the mean, of the weights has converged, then stop. Otherwise, go to step (1).

The core function provided by the package is the function AdMit. The main arguments of the function are: KERNEL, a kernel function of the target density on which the approximation is constructed. This function must contain the logical argument log. When log=TRUE, the function KERNEL returns the logarithm value of the kernel function; this is used for numerical stability. mu0 is the starting value of the first stage optimization; it is a vector whose length corresponds to the length of the first argument in KERNEL. SigmaO is the (symmetric positive definite) scale matrix of the first component. If a matrix is provided by the user, it is used as the scale matrix of the first component and then mu0 is used as the mode of the first component (instead of a starting value for optimization). control is a list of tuning parameters. For details, the reader is referred to the documentation manual (by typing ?AdMit). The last argument of AdMit is ... which allows the user to pass additional arguments to the function KERNEL.

Let us come back to our bivariate conditionally Normal distribution. First, we need to code the kernel:

```
>
  'GelmanMeng' <- function(x,log=TRUE)
    {
+
+
      if (is.vector(x))
+
         x <- matrix(x,nrow=1)</pre>
+
      r <- -.5*(5*x[,1]^2*x[,2]^2+x[,1]^2+x[,2]^2
+
            -10*x[,1]*x[,2]-6*x[,1]-7*x[,2])
+
      if (!log)
+
        r \leftarrow exp(r)
      as.vector(r)
+
    }
+
```

Note that the argument log is set to TRUE by default so that the function outputs the logarithm of the kernel. Moreover, the function is vectorized to speed up the computations. The contour plot of GelmanMeng is displayed in the left part of Figure 1. We now use the function AdMit to find a suitable approximation for the density whose kernel is GelmanMeng. We use the starting value mu0=c(0,0.1) for the first stage optimization and assign the result of the function to outAdMit.

```
> set.seed(1234)
> outAdMit<-AdMit(GelmanMeng,mu0=c(0,0.1))</pre>
> print(outAdMit)

The output of the function AdMit is a list. The first component is CV, a vector of length H which gives the value of the coefficient of variation of the importance sampling weights at each step of the adaptive fitting procedure. The second component is mit, a list which consists of four components giving information on the fitted mixture of Student-*t* distributions: p is a vector of length H of mixing probabilities, mu is a $H \times d$ matrix whose rows give the modes of the mixture components, Sigma is a $H \times d^2$ matrix whose rows give the scale matrices (in vector form) of the mixture components and df is the degrees of freedom of the Student-*t* components. The third component of the list returned by AdMit is summary. This is a data frame containing information on the adaptive fitting procedure. We refer the reader to the documentation manual for further details.

NLMINB

0.19 0.8807

For the kernel GelmanMeng, the approximation constructs a mixture of four components. The value of the coefficient of variation decreases from 8.0737 to 0.8807. A contour plot of the four-component ap-

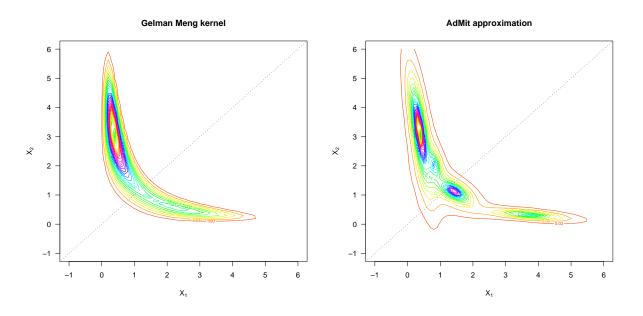

Figure 1: Left: contour plot of the kernel GelmanMeng. Right: contour plot of the four-component Student-*t* mixture approximation estimated by the function AdMit.

proximation is displayed in the right-hand side of Figure 1. This graph is produced using the function dMit which returns the density of the mixture given by the output outAdMit\$mit. The contour plot illustrates that the four-component mixture provides a good approximation of the density: the areas with substantial target density mass are *covered* by sufficient density mass of the mixture approximation.

Once the adaptive mixture of Student-*t* distributions is fitted to the density using a kernel, the approximation provided by AdMit is used as the importance sampling density in importance sampling or as the candidate density in the independence chain M-H algorithm.

The AdMit package contains the AdMitIS function which performs importance sampling using the mixture approximation in outAdMit\$mit as the importance density. The arguments of the function AdMitIS are: (i) N, the number of draws used in importance sampling; (ii) KERNEL, a kernel function of the target density; (iii) G, the function of which the expectation $\mathbb{E}_p |g(\mathbf{x})|$ is estimated; By default, the function G is the identity so that the function outputs a vector containing the mean estimates for the components of **x**. Alternative functions may be provided by the user to obtain other quantities of interest for $p(\mathbf{x})$. The only requirement is that the function outputs a matrix; (iv) mit, a list providing information on the mixture approximation; (v) ... allows additional parameters to be passed to the function KERNEL and/or G.

Let us apply the function AdMitIS to the kernel GelmanMeng using the approximation outAdMit\$mit:

> print(outAdMitIS)
\$ghat
[1] 0.9556 2.2465
\$NSE
[1] 0.003833 0.005639
\$RNE
[1] 0.6038 0.5536

The output of the function AdMitIS is a list. The first component is ghat, the importance sampling estimator of $\mathbb{E}_p |g(\mathbf{x})|$. The second component is NSE, a vector containing the numerical standard errors (the variation of the estimates that can be expected if the simulations were to be repeated) of the components of ghat. The third component is RNE, a vector containing the relative numerical efficiencies of the components of ghat (the ratio between an estimate of the variance of an estimator based on direct sampling and the importance sampling estimator's estimated variance with the same number of draws). RNE is an indicator of the efficiency of the chosen importance function; if target and importance densities coincide, RNE equals one, whereas a very poor importance density will have a RNE close to zero. Both NSE and RNE are estimated by the method given in Geweke (1989).

Further, the **AdMit** package contains the AdMitMH function which uses the mixture approximation in outAdMit\$mit as the candidate density in the independence chain M-H algorithm. The arguments of the function AdMitMH are: (i) N, the length of the MCMC sequence of draws; (ii) KERNEL, a kernel function of the target density; (iii) mit, a list providing information on the mixture approximation; (iv) ... allows additional parameters to be passed to the func-

> outAdMitIS<-AdMitIS(N=1e5,KERNEL=GelmanMeng, + mit=outAdMit\$mit)

tion KERNEL.

Let us apply the function AdMitMH to the kernel GelmanMeng using the approximation outAdMit\$mit:

> outAdMitMH<-AdMitMH(N=101000,KERNEL=GelmanMeng, + mit=outAdMit\$mit)

1-0

```
> print(outAdMitMH)
```

\$draws

	KI	KZ
1	7.429e-01	3.021e-01
2	7.429e-01	3.021e-01
3	7.429e-01	3.021e-01
4	1.352e+00	1.316e+00
5	1.011e+00	1.709e+00
6	1.011e+00	1.709e+00
7	1.005e+00	1.386e+00

1-1

\$accept

```
[1] 0.5119
```

The output of the function AdMitMH is a list of two components. The first component is draws, a $N \times d$ matrix containing draws from the target density $p(\mathbf{x})$ in its rows. The second component is accept, the acceptance rate of the independence chain M-H algorithm.

The package **coda** (Plummer et al., 2008) can be used to check the convergence of the MCMC chain and obtain quantities of interest for $p(\mathbf{x})$; the package is automatically loaded with the package **Ad-Mit**. Here, for simplicity, we discard the first 1'000 draws as a burn-in sample and transform the output outAdMitMH\$draws in a mcmc object using the function as.mcmc provided by **coda**. A summary of the MCMC chain can be obtained using summary:

```
> draws<-as.mcmc(outAdMitMH$draws[1001:101000,])
> colnames(draws)<-c("X1","X2")</pre>
```

```
> summary(draws)$stat
```

MeanSD Naive SE Time-series SEX1 0.96430.94760.0029960.004327X2 2.23881.32840.0042010.006232

We note that the mean estimates are close to the values obtained with the function AdMitIS. The relative numerical efficiency (RNE) can be computed from the output of the function summary by dividing the square of the numerical standard error of the mean estimates (Time-series SE) by the square of the naive estimator of the numerical standard error (Naive SE):

```
> stat<-summary(draws)$stat
> stat[,3]^2/stat[,4]^2
X1 X2
```

0.4795 0.4544

These relative numerical efficiencies reflect the good quality of the candidate density in the independence chain M-H algorithm.

The approach is compared to the standard Gibbs sampler, which is extremely easy to implement here since the full conditional densities are Normals. We generated N = 101000 draws from a Gibbs sampler using the first 1000 draws as a burn-in period. In this case, the RNE were 0.1013 and 0.1127, respectively. In Figure 2 we display the autocorrelogram for the MCMC output of the AdMitMH function (upper graphs) together with the autocorrelogram of the Gibbs (lower part). We clearly notice that the Gibbs sequence is mixing much more slowly, explaining the lower RNE values. This example illustrates the phenomenon that the autocorrelation in the Gibbs sequence may be high when assessing a non-elliptical distribution, and that the AdMit approach may overcome this.

Summary

This note presented the package **AdMit** which provides functions to approximate and sample from a certain target distribution given only a kernel of the target density function. The estimation procedure is fully automatic and thus avoids the time-consuming and difficult task of tuning a sampling algorithm. The use of the package has been illustrated in a bivariate bimodal distribution.

Interested users are referred to Ardia et al. (2008b) for a more complete discussion on the **AdMit** package. The article provides a more extensive introduction of the package usage as well as an illustration of the relevance of the AdMit procedure with the Bayesian estimation of a mixture of ARCH model fitted to foreign exchange log-returns data. The methodology is compared to standard cases of importance sampling and the Metropolis-Hastings algorithm using a naive candidate and with the Griddy-Gibbs approach. It is shown that for investigating means and particularly tails of the joint posterior distribution the AdMit approach is preferable.
