Paper prepared for presentation at the American Agricultural Economics Association Annual Meeting, Montreal, Canada, July 27-30, 2003

Introduction

The landscape plant industry has experienced a boom over the past fourteen years. Receipts have grown from approximately \$7.0 billion or 11 percent of all cash crop receipts in 1988 to \$14 billion in 2001. As with any industry of this magnitude, retailers have several challenges to address. One challenge retailers face is to develop a method to effectively identify and market to consumers likely to buy their products. By developing an efficient marketing strategy that focuses on a retailer's target market, a retailer not only cuts costs in its marketing program, but can also increase revenue through attracting new buyers.

An efficient marketing strategy focus can cut a retailer's costs. A retailer with a good focused marketing plan will spend less money on large-scale ad campaigns that reach everybody, including people non-buying consumers. An efficient marketing program can also increase revenue, through attracting new buyers that otherwise would not have been contacted.

The foundation of any good marketing strategy lies in market segmentation. After segmentation, a firm targets, which is the identification of an individual who is likely to patronize a particular type of retail outlet or to consume a particular type of product. By successfully identifying target markets, landscape plant retailers are able to make informed decisions, not only about advertising, but also about pricing and store location.

A retailer can segment its market by any number of variables. Any unique group, whether the distinction is by personal characteristics, such as age or race, by ideology, such as liberal and conservative, or by location, can be targeted as a market. The only qualification for a target market is that it has a propensity to consume the good being marketed. Generally, demographic and geographic characteristics are the most commonly used variables in market segmentation (Percy 2001).

This study seeks to aid in the identification of target markets for the landscape plant industry in Georgia. By using data collected over the years in a poll of Georgians, this study will determine what types of people are purchasers of plants at a particular type of retailer. Using the results, retailers and industry groups can develop marketing strategies designed to reach those who are most likely to buy landscape plants. By doing so, the industry positions itself to continue increasing its sales and to take advantage of and promote the explosive growth in demand for landscape plants.

Literature

Previous research dealing with market segmentation has focused on socioeconomic and demographic variables to identify target markets. Morrison suggests a logit regression to identify potential customers. Though this general analysis is a valid approach, landscape plant buyers have the option to buy their plants from different types of retailers. A logit regression would only identify likely purchasers of plants, not the type of retail outlet they are likely to patronize.

A 1988 study conducted by Turner, *et. al.*, examined the retail outlet choice of where Georgia consumers bought their landscape plants based on such factors as income, home value, race, age, sex, and educational levels. The different outlet choices were mass merchandisers such as Wal-mart, large garden centers such as Pike's, and local garden centers. By identifying the characteristics of consumers most likely to buy at a particular type of outlet, Turner, *et. al.*, was able to suggest marketing strategies that would benefit each type of outlet.

Turner, *et. al.*, found that all variables, with the exception of educational level, were significant for at least one type of outlet or another. The mass merchandisers' consisted of younger to middle aged populations in low to middle income socioeconomic groups, especially

minorities. Large garden centers captured the upper income single consumers, while local garden centers were favorite among married white females.

This study evolved from Turner's, *et. al.*, study, but is unique in several ways. Turner, *et. al.*, conducted his study with cross-sectional data covering the year 1988. In the ensuing 14 years, this data set has been expanded. The result is an unique panel data set that captures consumer purchasing habits and the changes in those habits over the past fourteen years. This study seeks to determine if the target markets for landscape plants Turner, *et. al.*, identified in 1988 have remained static over the past fourteen years.

Data and Empirical Methods

The data from this study comes from the Georgia Poll conducted by the University of Georgia's Survey Research center. The Georgia Poll is a random telephone survey of adult residents in Georgia conducted each year. From 1988 to 2002, the Georgia Poll contained questions relating to the landscape plant purchasing behavior of respondents. Together with demographic and socioeconomic characteristics, those questions constitute the variables under study. The pooled data this study uses was compiled from cross-sectional data from each year's poll. The descriptions for all variables can be found in Table 1 and the summary measures in Table 2.

This study assumes the percentage of landscape plants purchased at a particular retailer is a function of several different socioeconomic and demographic variables. Socioeconomic and demographic variables examined are age, race, education, marital status, sex, income, and home value.

The demographic variables are divided into dummy variables representing a particular characteristic. The race variables included in the model are white and black. To avoid perfect collinearity, hispanic, asian, and an “other” racial category were included in the intercept of the model. For marital status, married and single were included, while divorced, separated and widowed were left in the intercept. Under education, high school graduate and college graduate were represented in the model and all other education attainment levels were left in the intercept. Finally, a dummy variable for gender, with a value of one for females and zero for males was included. The socioeconomic variables are home market value and household income levels. Each was measured as a categorical measure. The complete pooled data set had approximately 7500 observations. After elimination of all observations with missing values and invalid responses, the data set contained 3394 valid observations.

The target markets for three major types of landscape retailers are of interest: mass merchandisers such as Home Depot, large garden centers, and local garden centers. Three other types of retail outlets were included in the survey, but the market share of these three outlets compared with the outlets under study were relatively small, and thus omitted from study. Separate functions are estimated for each type of outlet to identify the characteristics of consumers that are most likely to purchase plants at that type of outlet.

The dependent variable for each model is the percentage of landscape plants that each observation bought at that particular outlet. Values for these variables can take on any value between 0% and 100%, and the sum of the values over all the variables cannot exceed 100% for any single respondent.

Finally, to study the changes in target markets over time, the entire data set was divided into three periods. The first period covers five years from 1988-1992, the second spans the years

1993-1996, and the last period lasts from 1997-2002. A time dummy representing each period was then interacted with the other explanatory variables. Thus, the general model can be written as:

$$y_i = \alpha_1 T_1 + \alpha_2 T_2 + \alpha_3 T_3 + T_1 X_i \beta_1 + T_2 X_i \beta_2 + T_3 X_i \beta_3 + \varepsilon_i$$

where y_i is the percentage of plants bought at the particular retailer under study, T_1 - T_3 are time dummies representing the three time periods of the study period, X_i is the vector of demographic and socioeconomic variables, β_1 - β_3 are vectors of the corresponding regression coefficients and ε_i is a random error term. To examine the changes between time periods themselves, the intercept was suppressed. Three equations were estimated, one for each type of retail outlet. A Wald test was used to test for structural changes between time periods. The null hypotheses for the tests were that the coefficients for a variable were the same in two consecutive time periods.

Since this analysis examines the percentage of landscape plants that a consumer purchases, ordinary least squares is not the best estimation procedure. Often, a consumer will not purchase any plants from a particular type of outlet and no consumer can purchase a negative amount of plants. Therefore, the resulting data on purchase percentages is truncated at zero. For such equations, ordinary least squares results in biased estimates. In this case, a tobit procedure yields unbiased estimates.

Results

The first evidence of a shifting target market comes from examination of Figure 1. Figure 1 shows the market share for the major types of retailers through the study period. It shows how mass merchandisers have expanded their market share at the expense of every other type of retailer. Such a shift in market share almost certainly indicates a shift in target markets.

The overall shift in market share is confirmed by the results of the tobit regression for mass merchandisers, found in Table 3. A large shift in intercepts between the first and second period partially captures the effect seen graphically in Figure 1. This is the unexplained portion of the shift in average market share. Another portion of the shift in market share seen in Figure 1 can be attributed to shifts in target markets for the retailers.

The regression reveals several significant shifts in target markets for mass merchandisers. A list of coefficients that shifted significantly can be found in Table 4. To begin the study period, both socioeconomic variables, home value and household income, were shown to have a significant negative effect. As the study period progressed, significant shifts upward in both coefficients indicate that the mass merchandisers target market has shifted from low income to higher income demographics. Though there has been a shift upward, home market value still shows a negative sign, while household income is insignificant.

Demographically, the age coefficients both showed a significant change from the first period. While each was significant in the first period, they both became insignificant in the following periods. The white coefficient shows the opposite behavior, moving from insignificant in the first period to significant and negative in the next periods. The black coefficient moves from significance in the first two periods to insignificance in the last period. Finally, the regression shows a gradual move upward in importance of high school graduates, who not only move into significance, but also show stronger coefficients in each subsequent period.

In the first period, the mass merchants' target markets were lower to middle income earners, the middle aged, and African-American. These were precisely the groups that Turner, *et al.*, identified in 1988. Over the course of fourteen years, this target market has changed only slightly. Target market income levels have risen slightly, although the regression still shows that

the target market is lower to middle income earners. Reinforcing this result is the addition and growing importance of high school graduates in this retailer's target market. Minorities in general, not just African-Americans, are still part of the target market. Finally, age has ceased to be a factor for the mass merchants.

The large garden centers' target market in the first period, as can be seen in Table 7, was younger and well educated upper income females. This group is similar to the group that Turner, *et. al.*, identified in 1988. Through the study period, the target market experienced some significant shifts. A general intercept shift occurred between both time periods one and two and time periods two and three. The intercept shifted from insignificant in the first period to negative and significant in the following periods.

Demographically, the large garden centers experienced several shifts in their target market between periods one and two. Older people tended to buy more plants from these retailers as did whites and blacks. In period three, the only significant shifts in coefficients were as the race variables became reduced in their effects. However, all demographic variables dropped out of significance for the last period.

Home market remained very important in the calculation of the large garden centers' target market throughout the study period. Household income was important in the first two periods, but shifted into insignificance in the final period. The only significant variable in the third period was home market value.

Thus, higher socioeconomic class was still an important indicator of the large garden centers' target market. However, education, age, and gender are no longer significant indicators of this target market. This could be due to the erosion of market share that the large garden

centers have experienced at the hands of mass merchants. As the large garden centers' market gets smaller, their target markets shrink as well.

The target market for local garden centers in period one was found to be single or married male high school graduates. This group is slightly different from the target market that Turner, *et. al.*, identified in 1988. The only significant shift in coefficients for this retail outlet type was for the high school graduate coefficient between periods one and two, and was a shift from a positive effect to a negative effect. However, this variable also dropped out of significance at this point, and therefore does not indicate that better educated people became a part of this target market.

The only significant variable in the third time period for this retailer was the white racial variable. Over the study period, this racial group became increasingly important to the formulation of this target market. Insignificant in the first period, the coefficient for this variable became more significant over the duration of the study period.

The dearth of significant variables in the third period for this type of retailer could indicate that local garden centers are becoming a niche retailer. As mass merchants have taken over the major share of the market, local garden centers have seen their market share rapidly dwindle. To compensate, local retailers could be beginning to concentrate on consumer's specialty needs and other unique services not offered by mass merchants.

Discussion

Target markets for all three retail types have changed over the past fourteen years. Although some change is expected, the reduction in the number of target markets for large and

local garden centers is dramatic. Each went from having a target market consisting of several different types of characteristics, to each having a target market identified by a single demographic or socioeconomic variable.

As large and local garden centers have seen their target markets diminish, they have also seen their market share shrink. However, the situation for large garden centers is not as dire as that for local garden centers. Fortunately for the large garden centers, their target market is the most economically potent. By exploiting the large amount of disposable income of their target market, large garden centers can buffer the effects of their shrinking market share. Thus, the large garden centers are better able to compete directly with the mass merchants. However, mass merchants still have considerable advantages over their competitors.

Mass merchants have access to considerably more resources than their competitors. They are better equipped to handle adverse economic conditions and can expand more easily. At the beginning of the study period, mass merchants were a budding sector with resources similar to those of large garden centers. During the study period, the mass merchants experienced explosive growth. For example, Home Depot grew from only 96 total stores in 1988 to 1,532 with over \$58 billion in sales in 2002 (Website 2003a). This growth gave the mass merchants the ability to market landscape plants more efficiently than either large or local garden centers. The resulting expansion of market share and target markets for the mass merchant is not surprising.

Implications

As their target markets shrink, large and local garden centers need to explore new marketing strategies to remain in this market. Directly competing with mass merchants, while an

option early in the previous decade, is no longer a viable alternative. Although the mass merchants may seem to have every possible advantage due to their size and resources, there are several avenues that garden centers could pursue.

Local garden centers have an unlikely advantage. Since mass merchants are large and generally centralized organizations, they can not respond quickly to consumers' needs or overly specialize in an particular type of landscape plant. Local garden centers, because of their small size, are able to cater to unique and atypical consumer demands. By offering plants that are not readily found at the mass merchants, local garden centers could fill a niche market and will be able to thrive as a complement, not a substitute, to the mass merchants.

Otherwise, local garden centers can focus on rural markets. As mentioned above, mass merchants are not able to sustain themselves in these markets, whereas a smaller operation would be able to survive. As with offering more exotic plants, local garden centers in rural areas fill the market gaps left by mass merchants. By not directly competing with the mass merchants, local garden centers should be able to maintain a significant share of the landscape plant market.

Large garden centers are at a greater disadvantage than local garden centers. Large garden centers have an organizational structure similar to that of the mass merchants. Therefore it is less feasible for them to pursue niche markets like their smaller counterparts. However, large garden centers can take advantage of their target market of upper income individuals by borrowing a technique actually developed by one of their mass merchant competitors, Lowes.

Lowes primary business is supplies and material for do-it-yourself home improvement, but recently it has begun to offer professional installation services also. Large garden centers can differentiate themselves from mass merchants by offering professional landscaping and gardening services in addition to their regular inventory. By packaging the entire landscaping

process, from planning to planting, large garden centers could appeal to upper income consumers who may not have the time or inclination to create a garden, but do have the disposable income for a service to do it.

Mass merchants, as mentioned above, have access to several resources not available to the other two types of retailers. As a result, they have seen their market share grow and their target markets expand. Interestingly, as the mass merchants have expanded their market share and their target markets, they have successfully maintained their original target markets. This indicates a strong and efficient marketing strategy.

Mass merchants can continue to further expand their markets by expanding their marketing efforts to consumers who may come to their stores to buy other goods, not landscape plants. By bundling complement goods with plants and offering in-store discounts on plants, mass merchants can market to people who normally associate mass merchants with landscape hardware, not the actual plants, and to people who otherwise would not consider buying plants.

Conclusion

Landscape plant retailers have experienced a boom in business over the past fourteen years. With that boom comes the need for retailers to market more efficiently. The first step in developing an efficient marketing system is to identify a target market and then implement strategies to reach that target market. Additionally, knowing how and why a market became their target allows a retailer to strategically place themselves in an industry to take advantage of past and future changes.

Using fourteen years of data collected on Georgian's plant buying habits, this study conducted a tobit analysis on the target markets for three different types of landscape plant

retailers. This analysis not only examined the current target markets for those retailers, but also how those target markets have changed over time.

The analysis revealed that the target markets for mass merchandisers has not changed much from lower income minorities over the study period. This suggests that mass merchants are effectively and consistently reaching the same group and thereby retaining their patronage. Even the change in their target markets suggests an expansion, indicating that the mass merchants have successfully targeted groups outside of those who normally buy plants from them.

Target markets for large and local garden centers have suffered at the expense of this expansion. Large garden centers have seen their target markets shrink to include only upper income individuals and local garden centers have seen their target markets dwindle to include only the Caucasian racial group.

To combat this market share reduction, large and local garden centers need to consider alternative strategies to directly competing with mass merchants. Only by doing so will they be able to retain their current target markets and possibly begin expanding their markets once again. Failure to find ways to compete with the mass merchants will marginalize these retail type in the landscape plant market.
