Final Exam Scores in Introductory Economics Courses: Effect of Course Delivery Method and Proctoring. *Review of Agricultural Economics* 31(3), pp. 640-652.

ABSTRACT

Student performances on the final exam in introductory economics courses taught online and in the classroom were compared to consider the effect of proctoring the final exam. Students who took a course in the classroom did better on a proctored final exam than those taking the course online. Students in an online class taking a non-proctored final exam online scored more than one full letter grade higher than those taking a proctored final.

INTRODUCTION

It was not the usual environment that spurs academic inquiry. “I took that class online” said a family friend, referring to our department offered *Principles of Macroeconomics* course. He went on to describe “the system” his housemates used to overcome the challenge of collaborating (cheating) when student exams are individually prepared by random draw from large test banks. They took advantage of what Rowe refers to as the ‘birthday fallacy’. You may recall in a statistics course going around the classroom as each student indicates their birthday until there is a match, and perhaps your surprise at how quickly a match was revealed¹. In a class of just 30 students, the probability of a match is 71%. It increases to 90% with 41 students. The ‘birthday fallacy’ also explains why only a handful of students could collect many of a testbank’s questions even when the questions number in the hundreds.

The entrepreneurial students imported their pretest questions, drawn from the same testbank as the exam questions, into a word processing file. Students combined their files to create a “student testbank” for each chapter prior to taking their individual chapter exams in our online course. Enough participants in the scheme ensured that the students had most of the possible questions (and answers, since students pretests are graded immediately after they are completed) in the test bank. Having them in a word processing file allowed them to easily locate specific questions during exams using the search function. Essentially one student would read the beginning of a question and his “assistant” on a neighboring computer would search the file and provide the answer.

I inquired why they would embark on this elaborate scheme which surely took approximately the same amount of time and more coordination than simply learning the material before taking the exam. Surprised by the naivety of my question, he responded “we may not learn the material, but we are guaranteed an A.”

This conversation sparked my interest in better motivating students to learn the material in our online courses. My objective was to determine whether students enrolled in my class learned, understood, and were able to apply the material and, at least in the short run, retain this knowledge. Because the anecdotal evidence suggested I could not be sure if a student actually enrolled in the course was completing exams independently and without prior access to the questions and answers, I chose to employ use of a proctored final exam. My hypothesis was that including a proctored final exam and well-disclosing this from the onset of the course would improve student learning.

LITERATURE

Allen and Seaman, and Hogan and McKnight claim that, during a given semester, between 2.3 and 3.5 million students are taking an online course in the U.S., and that two-thirds of all academic institutions offer some online courses. Allen and Seaman computed the compounded annual growth rate in online courses over the past five years to be 21.5%. Student-based reasons for the popularity of on-line courses include the desire for additional flexibility in time and place and for independent learning. Institution-based reasons include attracting new students and growing continuing education programs, rather than to reduce cost (Allen and Seaman).

Relative Course Quality

There is considerable debate and some associated academic inquiry into the quality of online course offerings. Few would debate that quality is important in courses. The reputation of an academic institution is also at stake, whether it is measured by official accreditation or otherwise (e.g., reputation among employers). Some literature supports that online classes are of equivalent quality to their classroom-taught counterparts as measured in a variety of ways. For example, Dutton, Dutton, and Perry compared two sections of a computer programming course, one taught online and one in the classroom. Although online students performed better than those in the classroom, once students' grades were adjusted for other differences (e.g., programming experience, number of credits taken), course grades were equivalent between the two groups.

Other research, particularly in the field of economics, concludes that online courses do not offer the quality of their classroom counterparts. Anstine and Skidmore found that, although online students did as well as classroom students, they did not perform as well when their grade was adjusted for other factors that differentiated students. Coates et al. compared online and classroom course offerings by three instructors at three universities. End-of-class performance on the standardized Test of Understanding of College Economics (TUCE) was used to measure student-learning. Students in the classroom performed better than online students and this difference held even after analysis adjustments were made for effect of delivery method on performance and self-selection bias. The difference was especially notable for freshmen and sophomores, prompting the authors to advise against offering introductory economics courses in an online format.

Brown and Liedholm compared three course formats for introductory microeconomics. Online students did not perform as well as their classroom counterparts, but the authors concluded they would have performed better than their classroom counterparts if they had taken the class in the classroom. Online students performed comparably on definitional questions, but could not as well apply the material or respond to complex questions. Alternatively, they concluded that the performance of those taking the course offered in a hybrid format would not have changed substantially if they took the course either in the classroom or online. In general, students taking the course in the classroom put in more overall time than those taking the course online.

Stephenson, et al. also found that students performed better when enrolled in a traditional classroom-taught introductory microeconomics course than when taking an Internet-delivered course. This was particularly true for students with low SAT scores. They found the difference in performance lessened as SAT score increased. One revealed hypothesis is that distance education may be more appropriate for some students than others.

The literature on transactional distance as applied to education may also be of value in forming hypotheses and interpreting student success under different course formats. Transactional distance has been used as a framework to analyze differences in student interest, student learning, and student evaluation of instruction (Lemak, et al). This theory considers rigidity of course structure and level of student – instructor interaction. It has been used to investigate how course outcomes are affected by course structure and dialogue, when they differ by method of course delivery. Lemak, et al. found instructor effectiveness ratings were positively correlated with measures reflecting degree of course dialogue, and negatively correlated with those reflecting degree of course structure. Whether the students were physically located with the instructor or their classroom was linked to the instructor by a telecommunications system did not affect student evaluations of instructor effectiveness.

Another quality issue is that of course completion. In general, the literature that explores course retention concludes that online students are less likely to complete a course than their classroom counterparts. Dutton, Dutton, and Perry found the difference disappeared once they accounted for the number of credit hours the student was currently taking, with those students taking more credit hours being more likely to complete the course. This again raises the question of whether the student audiences are the same for online versus classroom offerings. The literature in general supports that they are not. Vachris argues that online courses generally take more effort and therefore entice more active and independent learners. Dutton, Dutton, and Perry argue that online students are different, not only demographically, but behaviorally and by what is important to them. Brown and Liedholm found that online students had higher ACT scores and had already completed more credits.

Faculty Acceptance

Faculty concerns about quality of online courses are especially commonplace. Allen and Seaman report that the two most critical barriers facing on-line education as elicited from academic leaders are faculty acceptance and a need for more discipline on the part of students. Four-year institutions have the lowest level of faculty acceptance. Only 15% of academic leaders at these institutions reported that their faculty accept and find legitimate online courses.

Thoughts regarding the role of online classes are not particularly well defined at our own academic institution, but within our department, faculty range from vocal skeptics to those who are moving forward with online course offerings for what they presumably personally believe is the greater good, including the author. Add some rational but anecdotally-based skepticism to the previously-discussed findings on comparative course quality and you have the natural question of whether our online introductory economics courses are ‘at least as good’ as our

classroom courses. There is plenty of debate about, not only this basic question, but even about the definition of quality. Defining quality is not the purpose of this paper. Suffice to say, however, that groups of students working together to respond to exam questions without learning the material is not quality. Therefore, I sought to measure student performance in a controlled (proctored) environment.

METHODS

Although admittedly and perhaps the initial rationale for a proctored unaided final exam was to punish those who cheated or “cheated themselves” by not learning the material, this research does not allow one to speak to whether relative performance on the final exam is indicative of cheating on assessments prior to the final exam or if students did not learn simply because it was unnecessary to do so (e.g., because materials could be used during prior assessments). In fact, it only allows for consideration of performance on a final exam, and whether observable differences in student performance on exams and class (class, term of offering, online versus classroom offering, proctored or non-proctored final) can explain performance.

The initial design and later revisions of our online introductory economics courses have taken recommendations from the literature about how to minimize cheating and motivate learning into account. The importance of a social environment that does not allow nor tolerate cheating is stressed. Our University and College honor codes are shared and explained throughout the course (syllabus, audio-introduction, announcements). The College honor code stresses the presumption of innocence and the student’s responsibility to police themselves and their fellow classmates. To make it more difficult for students to work collaboratively, students complete pretests and exams for individual chapters which are comprised of randomly drawn questions from large test banks². Alternatively, in our classroom-taught courses where all exams are taken simultaneously by students and are proctored, the same exam is offered to each student. And, in my online courses, a proctored final exam is added when a majority of students are on campus (i.e., during the academic year, but not during the summer)³. The weight on the final exam is large enough to motivate them to be prepared.

There is some evidence from the literature that supports that cheating in economics courses may be greater when the exam is not proctored. Harmon and Lambrinos concluded that there was cheating on a non-proctored final exam by comparing the R^2 of models that estimated final exam score as a function of various indicators, including score on three non-proctored exams, for an online and a classroom course.

In the current study, I offered three different courses under a variety of environments (online versus classroom, eight-week summer term versus 16-week academic term, and with a proctored versus an unproctored final exam). It is therefore possible to determine whether my effort to improve learning by including a proctored final exam was successful.

The Model

Performance on the final exam is estimated as a linear function of average exam performance with dummy variables used to represent the course, if it was offered in the classroom or online, and whether the final exam was proctored (Equation 1).

$$(1) \text{Final}_i = \alpha + \beta_1 \text{Exam}_i + \beta_2 \text{Course}_i + \beta_3 \text{Classroom}_i + \beta_4 \text{Noproctor}_i + \epsilon_i \text{ for } i = 1, 2, \dots, n.$$

Where:

B_i are the estimated coefficients and ϵ_i is the random error term.

Final_i = percentage performance on the final exam for student i

Exam_i = average percentage performance on chapter (online) or midterm (classroom) exams for student i

Course = one or more dummy variables denoting the course or courses. In the initial model, dummy variables are included to depict non-base case courses where

ECON 201 (Principles of Microeconomics) = 1 if course is Econ 201, 0 otherwise

ECON 105 (Elements of Economics) = 1 if course is Econ 105, 0 otherwise.

Classroom = 1 if course was offered in the classroom, 0 if it was offered online

No Proctor = 1 if the final exam was taken online, 0 if it was proctored.

The base case is ECON 202 (Principles of Macroeconomics).

Courses

Data from three courses taught by the same instructor were included. Each course used Blackboard® as a delivery mechanism for course information (e.g., syllabus, audio introduction), materials (e.g., lecture notes), and announcements. In each online-, but not classroom-taught, course, students were allowed to use materials (e.g., notes, textbook) during completion of assignments, pretests, and exams, but were not allowed to receive human assistance. Specific examples of what was allowed (e.g., use of textbook and notes) and not allowed (e.g., receiving aid from a friend, having another individual complete the work) were provided during the audio introduction and specified in the syllabus.

ECON 105, Elements of Economics, is an introductory course including both micro- and macroeconomic principles. It is designed for non-majors. It was taught online in the spring of 2007. DiscoverEcon®, a commercial online assessment package tailored to a specific textbook, was used for assignments, pretests, and exams. The textbook used was Elements of Economics by Schiller. Students completed a pretest and exam for each assigned chapter of their textbook. The pretest grade was their initial and only attempt and students were instructed to complete the chapter pretest only after reading their textbook and completing chapter assignments. It was to be used by students to check their understanding prior to taking the exam. The recorded exam

score was their last attempt. Students were allowed to retake each exam until they were satisfied with their performance⁴. The final exam was proctored and was comprised of an approximately equal number of questions for each chapter from the DiscoverEcon® question banks (i.e., question banks used for the pretests and exams). Most students took the final exam during finals week in an auditorium at one of two available times. By exception, final exams were individually proctored by support staff, a clergyman, or a faculty member at another university.

ECON 201, Principles of Microeconomics, and ECON 202, Principles of Macroeconomics, were both offered in the classroom during an eight-week summer term in 2006. Three midterm exams and a final were proctored. Econ 201 was offered online during the summer of 2007. Econ 202 was offered online during the spring and summer of 2007. Online offerings of both classes relied on Blackboard© to provide course information, materials, and announcements. Students also took chapter pretests and exams in Blackboard© with questions drawn randomly from a test bank provided by the textbook publisher. Pretests were ten questions and were not timed. Exams consisted of 25 questions and students were limited to 50 minutes to complete each exam. As noted previously, individual chapter rather than midterm exams were used and a time limit imposed to reduce the likelihood students would seek outside assistance during exams. About one-quarter of the student's grade was their performance on chapter assignments in Aplia©, an economics homework management package tailored to the specific textbook used and available on the Internet. The textbook used was Economics by McConnell and Brue. The final exam for the online-offered ECON 202 during spring term, 2007 was proctored, but those for the online 201 and 202 courses during the summer 2007 were not.

Exam questions for the final exams in all classes over all terms came from the test bank offered by the publisher and reflected an approximately even number of questions from each chapter. Questions were screened carefully for content and level of difficulty. All fifty questions on the proctored final exams were the same across students in a class, and the same final exam was used in the summer 2006 and spring 2007 ECON 202 courses. The final exams used in the online offering of ECON 201 and ECON 202 during the summer 2007 were updated to reflect a new edition of the textbook (and an updated accompanying test bank). Except for slight changes, content and level of difficulty did not differ. Content was directly compared between exams to gauge level of difficulty. Table 1 provides a summary of course details and final exam scores. Ordinary least squares was used to estimate performance on the final exam as a function of specified attributes as previously described.

RESULTS

The included variables explained 62.7% of variation in final exam performance (adjusted $R^2 = .616$) (table 2). The coefficient on average percentage on chapter or midterm exams was significant and, at .816, as expected, it was reasonably close to one. When the student sample was limited to only students in ECON 202, the correlation between average exam and final exam scores was lower when the final exam was proctored (.534, $p = .004$) than when the final exam was not proctored (.917, $p = .000$). Students in ECON 105 did substantially worse on their final

exam than those in ECON 202 (the base case) and the coefficient was highly significant. The average final exam score in ECON 105 (proctored final) was only 50.94, compared to 71.67 over all offerings of ECON 201 and 202. The average for the ECON 105 final was also a full letter grade lower than that for the same semester ECON 202 class which was also offered online and also had a proctored final exam (50.94 versus 60.74, $p = .002$).

When other differences were accounted for, students who took the course in the traditional classroom environment (during the summer of 2006) did substantially better than those students taking the courses online. The estimated coefficient indicates the advantage for the classroom students as 17.87 percent. And, all else equal, those students taking a non-proctored final exam did substantially better than those taking a proctored final exam. The associated estimated coefficient is 13.10.

The model variables were changed slightly to test the robustness of the model. The two dummy variables allowing for estimation of class effect were reduced to one which reflected whether the course was ECON 105 or was one of the principles courses. ECON 105 was only taught online and course format differed considerably from that of the online offerings of ECON 201 and 202, which were very similar to one another. The explanatory power of the model did not change ($R^2 = .626$, adjusted $R^2 = .617$) and estimated coefficients changed very little.

To test for differences in student performance on the final exam between online sections when the final was proctored and those when it was not, the estimate was run only including online students. Again, estimated coefficient parameters and the explanatory power of the estimate changed very little. Students taking a non-proctored final exam and allowed access to their textbook and notes scored more than one full letter grade higher than those taking a proctored final.

Principles of Macroeconomics, ECON 202

Consideration was next limited to a single course. Data from the three sections of ECON 202 were considered: Summer 2006 (classroom with proctored final), spring 2007 (online, proctored final), and summer 2007 (online, non-proctored final). Results are similar to those obtained from the previous models (table 3). Again, the coefficient on the exam performance variable was close to one. Accounting for other factors, those taking the course and completing their exam in the classroom did much better than those taking the course online, but also completing their final in a proctored classroom environment. These results are not unexpected looking at the average percentage score on the final exam for the three sections. The summer 2006 (80.00) and summer 2007 (78.57) averages were not different. Presumably, the classroom environment approximately compensated for the proctored final when compared to the online environment with a non-proctored final exam. In other words, although students taking the course in the classroom did not benefit from the open-note and open-book final enjoyed by their online counterparts, they did as well.

DISCUSSION

The estimated coefficient on the variable representing students' average exam score was close to one and was always significant, indicating that students who did better on the final exam also did better on chapter or midterm exams. The relatively poor performance of students enrolled in ECON 105 on the proctored final exam relative to students in other classes lends itself to the conclusion that the assignments in DiscoverEcon® and/or the method of allowing students to retake their exams until they are satisfied with the grade were not conducive to student mastery of the material. The rationale behind allowing multiple attempts on each exam was that students would learn the material better if they worked additional problems (i.e., took the exam more than once). Because there was no time limit on exams, the expectation was that students would use their textbook and notes to determine the answers, similar to working homework problems. Although this was not successful, it is not clear why. A careful review of the assignments and exams in DiscoverEcon® is warranted. It is also important I consider whether the 'birthday fallacy' may have resulted in some students simply learning the questions (and answers) for each chapter prior to taking their record (last) exam for the chapter. This could be accomplished independently in this class because students were allowed an unlimited number of attempts on the exams.

The classroom environment apparently aided students in preparing for the final exam. The relevant question is how? One hypothesis is that the small class size and / or the classroom environment motivated student understanding and retention. In the classroom, new material was covered more consciously as building upon previous material. A regular review of previously-covered material was offered by the instructor as the course progressed. Problems were regularly worked in class, allowing students to master the material as it was covered. Relevance to current events was regularly discussed, facilitated by the instructor- (rather than self-) paced nature of the course. Students in the classroom also took three closed-notes, closed-book midterm exams rather than open-note, open-book exams for each individual chapter offered to online students, the latter designed to reduce the likelihood of collaborative work. For classroom students, the proctored final exam was taken in the same environment as their midterm exams, but simply covered more material. And, like the final exam, their mid-term exams required knowledge and understanding of material from multiple chapters. For online students, the proctored exam was unlike their previous experiences in assessment for this class, because it was on paper and was proctored, use of routine materials was not allowed, and it covered multiple (in this case all of the) chapters assigned.

Evidence indicates online students did not perform as well as their classroom counterparts, especially when they were required to take a proctored final exam. One hypothesis supported by Brown and Liedholm and casual observation of the exam completion process of our own students is that our online students did not spend enough time with the material. Many online students completed a large number of exams during the last week of the class. And, few students in the principles courses completed the practice problem sets assigned in Aplia®, but rather only completed the graded set for each chapter. This was disappointing because the

practice sets, but not the graded sets, provided immediate feedback and additional tutoring. I do not have a good estimate of the amount of time students invested in each course. In future courses, this information can be tracked either through students volunteering the information (e.g., a survey or course activity diaries) or can be estimated by considering the amount of time students are online viewing or completing course materials.

It is clear that student expectations of the time required to complete the course were not well aligned with the actual time required. From their typed comments on the course evaluation instrument and from student emails, it appears many believed that a semester-long online course can be completed in a dedicated weekend or two (e.g., several explained they did not complete the last five to ten chapters because they unexpectedly had to go out of town for the weekend, were ill, and so on).

Regardless of precisely why students in the online courses did not perform well on a proctored final exam, the lesson is that students did not succeed. They were not required to learn the material to succeed on chapter-level assessments, or the individual chapter exam format did not encourage semester-long retention. An important limitation of this research is that information was not available about the characteristics and background of students. It was therefore not possible to identify how they influenced success. What is clear is that online students were not, in general, successful on a proctored final exam. Because of the limitation associated with lack of information on individual students, we look to the literature for suggestions for how we might better help students succeed. This results in the following recommendations to motivate student learning in our online courses.

- Retain the proctored final exam, and continue to announce this early, often, and broadly so students are ever-conscious that they will be responsible for the material in an un-aided environment. That is, that they will be expected to learn it, retain it, and know how to apply it.
- Ensure computer exam questions concentrate on application and more complex assessment questions to encourage active thinking versus looking up material. It is possible to select questions from the test-bank for the exam pool based on the type of question. This feature should be employed to limit the number of definition and general knowledge questions students face, as this information can easily be looked up during the assessment and, hence, does not require prior learning.
- Train students early to read, understand and practice. Require additional homework problems, coincidentally being beta-tested online by the publisher of the textbook used for Principles of Microeconomics and Principles of Macroeconomics. Further, require or otherwise motivate students to complete practice homework problems in Aplia©. Perhaps reduce the number of questions in both the practice and the graded problem sets to decrease the required time commitment of completing both. Ask students to write short papers describing a current event using economic concepts (e.g., why we have witnessed dramatic changes in the price of gasoline). The downside is that this will require an additional time commitment on the part of the instructor, and hence may limit the number

of students who can enroll in the class, but this is true whether the class is online or in the classroom.

- Continue to tell students early, often, and in a variety of ways that the course may be time consuming relative to their expectations. A suggested schedule is provided to allow students to complete the course at a steady-pace and finish on time. Few students follow the suggested schedule. The initial three chapters must be completed one-quarter of the way into the course. This is to ensure that students understand the commitment and have a good idea of the time each chapter will require. However, students often stop working on the course once these chapters are completed, only to rush to complete the remaining chapters during the last week or two of class. While more difficult to manage, and somewhat against the nature of a self-paced online course, a second and perhaps additional deadlines would help students keep on track. And, it might help students overcome self-discipline problems noted by 80% of academic leaders (Allen and Seaman).
- Otherwise regularly engage students in the class. Regular announcements are posted in Blackboard© and a new feature allows these announcements to simultaneously be emailed to students. However, the self-paced nature of the course has somewhat hindered the effectiveness of subject matter and discussion in messages designed to demonstrate relevance of course material to everyday life. Additional pacing would allow instructor-student or student-student discussion that relied on a specific level or breadth of subject matter knowledge. It would also facilitate additional means of engaging students such as chat sessions regarding material covered throughout the course. This would fit within the framework of the transactional distance literature which suggests that increased instructor – student interaction may improve student learning. It may also provide additional information to the instructor which could be used to adapt course content and especially feedback and instruction to the students throughout the course based on their revealed understanding of the material.

Coates et al. concluded that teaching principles of economics courses online is a bad idea, in part because their research showed that freshmen and sophomores are especially disadvantaged by their online delivery. However, nationally, two-year schools offer the fastest growth rate of online course offerings (Allen and Seaman). In light of these challenges, retaining in-house quality control for the fundamentals courses supporting our academic majors may be a compelling reason to continue to grow our offerings of online courses, and to make these more widely available to off-campus learners and those at partner schools.

Endnotes

1. This is of course because the probability of a match is calculated as

$$1 - \frac{(365)(364) \dots (365 - n + 1)}{365^n} .$$

2. I am cognizant of the risk that individual chapter assessments may emphasize and encourage short term memory rather than long term understanding (Rowe).

3. Other useful ideas were gleaned from the popular literature, but not employed for these particular classes. They include issuing an identification number and password to each student just prior to them taking the exam, use of a webcam to record students as they take the exams, use of a lock-down browser to disable students' ability to cut and paste or save material, or access other programs including the Internet, and to require students to inform the instructor via telephone or email immediately at the time of a technical problem with their computer access to assessment instruments.

4. In retrospect, enterprising students might have thought to take the exam prior to the pretest. It draws from the same test bank and can be retaken, allowing students to practice prior to their sole attempt at the pretest.
