# What is an Award Worth? An Econometric Assessment of the Impact of Awards on Employee Performance

## Abstract

Behavioral economics documents the importance of status and self-image concerns in the workplace, but is largely silent about how to instrumentalize them to induce effort. Awards - widespread in the corporate sector and elsewhere - are motivators that derive their value from such social concerns. Panel data from the call center of a large international bank allow us to estimate the impact of receiving an award on effort. The performance of winners proves to be significantly higher than that of comparable non-recipients after the award has been presented. This increase in work effort is sizeable, robust, and not driven by reverse causation.

JEL Code: C23, J33, M52.

Keywords: awards, motivation, non-monetary compensation, event-study, incentives.

We also thank the participants of the various seminars and conferences where this paper was presented for their feedback.

“If an organization is going to function well,  
it should not rely solely on monetary compensation schemes.”

Akerlof and Kranton (2005)

## 1 Introduction

Awards are increasingly popular in the corporate sector, where managers consider innovative human resource practices, such as awards, to be essential for firm competitiveness (Ichniowski and Shaw 2003). In his book *1001 Ways to Reward Employees*, Nelson (2005) provides ample evidence of the number and variety of awards in companies. The prevalence and popularity of awards in the corporate sector suggest that awards fulfill important functions in principal-agent relationships. However, to date there is no clear empirical evidence on the effect of these kinds of social incentives on performance.

Using an event study technique that exploits the matched nature of our panel data, we are able to causally identify the effect of receiving an award on subsequent employee performance in the call center of a large international bank. Specifically, the data set is unique in that the awards studied are directed towards valuable activities such as substituting for colleagues or making improvement suggestions, which are uncorrelated with the performance measured in the call center. This feature ensures the exogeneity of the intervention. We find that award winners substantially increase their subsequent performance relative to both nonrecipients and their own previous performance. This result is robust to alternative specifications that check the validity of the identifying assumption and the specifics of the econometric technique used. Hence, the receipt of an award enhances performance even in job dimensions that are not incentivized with the award. The documented ex-post performance enhancement adds to the presumably positive impact on the rewarded activity itself and the incentive effect of the award system per se, and it suggests that awards are valuable incentive instruments that should be taken seriously as additional instruments in

principal-agent relationships.

How do these predominantly nonmonetary, reputation-based rewards fit into the economic literature where they have been basically ignored to date? Previously, when economists studied incentives in organizations, the focus was on monetary payments in exchange for performance on specific, measurable dimensions. This is illustrated by the large literature on incentive pay to align the interests of principal and agent starting with the pioneering works by Alchian and Demsetz (1972) and Jensen and Meckling (1976). In recent years, works in behavioral economics have explored a wider set of motivations in the workplace such as status (Auriol and Renault 2008), concerns for social recognition (Brennan and Pettit 2004) and positive self-image (Bénabou and Tirole 2002), feedback (Suvorov and van de Ven 2006), and identity (Akerlof and Kranton 2005). However, this literature has largely been silent about how these social concerns can be instrumentalized to induce effort in a systematic and predictable way.

Awards are a widely used means of motivating workers in organizations and we argue that they derive their value from these kinds of social concerns. In award schemes, an agent is given a symbolic reward for good performance in combination with positive performance feedback and social recognition from superiors and peers. The value of an award depends on its scarcity as a positional good as well as on the usefulness of the performance feedback and the appreciation of the recognition. While there is no universally accepted definition of awards, essential elements are (1) the publicity of the winners, (2) a set of deliberately vague evaluation criteria, (3) the unenforceability of awards, and (4) their tournament character. Although awards contain features of other motivators, such as performance bonuses, pure feedback, gifts, and praise, they can be clearly distinguished from them.

We are aware of only a few other papers that explicitly study awards. Hansen and Weisbrod (1972) and Frey (2005) address awards as incentives in general. Markham, Scott,

and McKee (2002) show in a quasi-experimental setting that the introduction of a public recognition program to reduce absenteeism decreases the latter by 52 percent. Gavrila et al. (2005) describe the optimal solution for the management of awards over time, considering that their incentive effect depends on the number of awards that are presented. Besley and Ghatak (2008) analyze a principal-agent setting with social incentives, such as job titles or awards. The decisive feature of these rewards is that they have zero marginal costs, so it is incentive compatible for the principal to award them even if the payoff is not verifiable. Elsewhere, we show that awards act as incentives, significantly influencing performance before they are presented (Neckermann and Frey 2008; Neckermann and Kosfeld 2008). Malmendier and Tate (2008) also show how the receipt of a title, like “CEO of the Year,” affects subsequent performance. However, their paper is concerned with extra-organizational awards that are exogenous to the principal-agent relationship of interest. These kinds of awards differ in essential ways from intra-organizational awards. They are presented by a person or institution that is not the principal of the agent whose performance is affected, for a different set of reasons, and they come with a different set of benefits for the recipient. Therefore, their findings cannot be generalized to intra-organizational awards.

This paper contributes to the discussion of rewards by presenting the first empirical evidence on the effect of receiving these kinds of social incentives on performance. This suggests that the traditional focus on monetary incentives is too narrow because other motivators, tapped by instruments such as awards, have a significant and systematic effect on employee performance. Further, we show that such rewards have an independent positive effect on behavior after they are awarded; hence, it is not sufficient to consider only the ex-ante incentive effect of rewards, that is, while employees work towards receiving them. The significant behavioral effect of these social incentives also fits well into the current discussion on the disparity between the impact of monetary incentives in the lab and in

the field. While lab studies find a large behavioral effect of wage increases, effort reacts relatively little in the field. Some authors (see, e.g., Dur [2008]) argue that this divergence is caused by the fact that employers in the field typically use motivators other than wages, for example, recognition, to signal kind intentions. Therefore, employees do not reciprocate to wage increases in the field to the extent they do in the lab, where money is the only means of signaling kind intentions.

Section II presents the data and the estimation technique. In Section III, the empirical findings are discussed and Section IV concludes.

## **2 Data**

The data set comprises information on awards as well as the employee performance of the 155 call center agents of a credit card service company of a large international bank and covers the period from January 2004 to October 2007. The call center is responsible for handling customer complaints and questions and consists of six work groups, each with one group manager. Management considers the call center of key importance for the company's success because it represents an important interface between the company and its customers.

### **2.1 Dependent Variable: Performance**

The company records daily performance for a number of different performance dimensions, starting in the second month of employment to allow for initial learning. On a monthly and yearly basis, these measures are transformed into rankings and aggregated into a single performance index. In particular, for each dimension, the percentage deviation between individual performance and the average monthly performance of all the call center agents is calculated and changed into a rating between 5 (very good) and 1 (unsatisfactory),

according to a matrix set up by the department head. As an example, an agent that performs 120 percent of the average performance in a dimension receives a rating of 5 in that dimension, and an agent whose performance is 80 percent or lower receives a rating of 1. The relative nature of the performance measurement is an advantage for our study because it ensures that all time-varying, exogenous factors that affect the absolute performance of all call center agents are excluded.<sup>1</sup> Specifically, the measurement is not affected by an increase in the number or difficulty of calls or by improvements in the technical infrastructure. Both of these factors render absolute performance incomparable over time. In line with exerted effort, the relative rating further ensures that a certain number of calls answered translates into a higher rating in slow rather than in busy months. We basically use the same index as the company to ensure that our performance measure corresponds to the company's assessment of good and bad performance. Because the company continually refines the exact calculation of its performance index by adding and removing different performance dimensions from it, a core performance measure was constructed in collaboration with the call center manager. Our performance index comprises the following six dimensions that have been part of the company's index in all of the periods covered:<sup>2</sup>

1. Calls Taken Per Hour: Average number of phone calls handled per hour.

---

<sup>1</sup>Theoretically, relative performance measures may have the downside that a change in ratings may not always reflect corresponding changes in effort; hence, ratings may not be comparable across months. This is the case when a variation in the average absolute performance causes a given effort to translate into different ratings in different months. In our setting, however, absolute performance does not exhibit a systematic trend and typically changes only very little between two months in all dimensions. Moreover, the nature of the task renders it highly unlikely that employee fluctuation causes changes in ability distributions dramatic enough to have a sizeable impact on absolute performance. Therefore, any change in absolute performance that we observe likely reflects changes in working conditions that should be filtered out.

<sup>2</sup>The company's changes in the index do not reflect systematic and sustained improvements of performance evaluation, which would have suggested that we should use the changing index too. Rather all dimensions that are not captured in our core rating were added and removed at various instances. Examples are the two dimensions *Training*, which measures an employee's performance in in-house training courses, and *Write off Policy*, which measures the degree to which employees follow company guidelines on goodwill issues. Both dimensions were in the company's index only in 2006.

2. Call Handling Time: Average length of phone call.
3. After Call Worktime: Average amount of time needed to process the request after the call has been ended.
4. Transfer Rate: The average ratio between calls handled by the employee and the number of phone calls that were transferred to colleagues or other service units.
5. Lates: Number of days on which the employee showed up late for work.
6. Quality: Quality of client handling as assessed by supervisors and clients.<sup>3</sup>

Of these dimensions, only the dimension *Lates* is not evaluated relatively, but according to an absolute scale (no absence corresponds to a rating of 4, one absence to a rating of 3, and more than one absence to a rating of 1). The resulting six ratings are then combined to a single overall rating according to the same weighting scheme used by the company.<sup>4</sup> Specifically, *Quality* enters with a weight of 50 percent and the five other dimensions with 10 percent each. The weighting scheme suggests that the company places equal emphasis on technical measures, such as the number and durations of calls, and content measures, which capture the actual interaction between employee and customer. The resulting index provides a global, overall assessment of performance. It captures all the relevant trade-offs the company faces, ensuring that employees do not improve their rating, for instance, by answering more calls at the expense of call quality. The management confirmed that our

---

<sup>3</sup>The rating has an internal and an external component, each of which accounts for 50 percent of the quality rating. Internal quality is assessed by the group manager by periodically monitoring the conversations of each agent. The assessment follows a clear set of rules and guidelines that leave virtually no room for subjectivity and thereby ensure the objectivity of the measure. Evaluation criteria are, for example, whether the agent correctly introduces herself and asks the right set of questions in the prescribed order. The external quality rating is generated by an outside company that conducts surveys with the company's customers.

<sup>4</sup>The addition and deletion of performance dimensions in the company's indices in different years were accompanied by changes in the weights of the individual dimensions. However, the relative weights of the six core performance dimensions remained basically identical throughout the entire time period covered.

core index captured overall performance well and that no important performance dimension was neglected. Figure 1 exhibits the density of performance ratings.

The performance ratings are approximately normally distributed with an average of 3.02 and a standard deviation of 0.66 and do not exhibit a time trend. The mean and variation corroborate the objective, quantitative nature of our performance data, as subjectively determined evaluation data typically cluster around high values (on the leniency bias see, e.g., Murphy and Cleveland [1995]; Yariv [2006]) and may cause endogeneity problems because managers might assess award-receiving individuals more favorably. The resulting

index represents a weighted average of quantitative performance measures. Thus, we can treat the rating as cardinal because it takes on many different values and does not have the quality of an ordinal grading scheme.

## 2.2 Independent Variables: Awards

The company has a variety of awards. These are called the *Thank You Reward*, the *Gold Reward*, the *Platinum Reward*, the *President Reward*, *Employee of the Month*, and *Employee of the Year*. The requirements for qualifying for these awards increase from *Thank You Reward* to *Employee of the Year*. While a *Thank You Reward*, an email notification and a letter sent to the employee's home address, allows a spontaneous exchange of thanks among colleagues, the *President Reward* remunerates activities that have benefited the company as a whole; these require approval by the CEO and come with a personal congratulation by the department head. The winners of *Employee of the Month* and *Employee of the Year* are selected by a reward committee and the CEO from among the winners of the *Platinum* and *President Rewards*. For all awards, there is a close connection between effort and likelihood of nomination, so that individuals can actively pursue winning an award. Appendix A. contains a full description of the awards, their requirements, approval procedures, and associated benefits. The award program of the company has been in place since 2001. Therefore, we cannot estimate how the presence of the award system per se changes performance because there is no control group without awards. Rather, this ex-ante incentive effect of awards is part of the baseline motivation of each employee and constant throughout the period of our study.<sup>5</sup>

While our data set contains information on the winners of all awards other than the *Thank you Reward*, only the *Gold Reward* lends itself to a statistical examination be-

---

<sup>5</sup>This incentive effect potentially changes with winning an award. One might argue that the motivation to win decreases once an award has been won. However, such a potential change in baseline motivation renders the detection of a positive change in performance caused by the receipt of an award more difficult.

cause there are too few observations of call center agents winning the other, more prestigious awards. The *Gold Reward* remunerates exceptional efforts that benefit the entire work group. Nominations can be made by colleagues as well as supervisors.<sup>6</sup> An award is presented by the call center manager in front of the worker's colleagues in the middle of the following month. Award winners, as well as their colleagues, only learn about the award then. There is no additional announcement of the award winners; however, the management takes care to present the award when many colleagues are on hand, that is, the entire call center as all call center agents work in one big office. The award is accompanied by a certificate for the wall, which serves as a reminder and ensures that agents not present when the award is presented learn about it, as well as a symbolic bonus of around Swiss Franc (CHF) 150. Examples of behaviors that qualify for a *Gold Reward* are volunteering as a substitute during vacation times, initiating and implementing team events, making improvement suggestions, and helping others with good advice. Importantly, awards are not presented for the performance used as the dependent variable in our analysis. In fact, core performance is uncorrelated with the activities that lead to an award. Awards are therefore exogenous, and their causal effect on core performance can be identified by comparing the performance of winners and nonrecipients subsequent to winning. If awards depended on performance, they would always be—at least, in part—a reflection of good performance, and a careful creation of control groups would be necessary to identify the causal effect.

The data set comprises 46 awards (*Gold Reward January 2004* to *Gold Reward October 2007*). Overall, 158 *Gold Rewards* were presented to the 155 call center agents between 2004 and 2007. As expected, the distribution is skewed to the right. Two agents received

---

<sup>6</sup>About half of the nominations come from group supervisors and the other half from colleagues. The reasons provided for the nominations do not differ systematically between those by supervisors and colleagues. The Human Resources Department communicates the criteria for nominations well, so almost all nominations result in an award. Interviews with group managers and employees further suggest that employees deserving an award are not ignored, especially as so many individuals can nominate.

a total of eight *Gold Rewards*, whereas 76 got none.<sup>7</sup> These numbers suggest that the award is sufficiently scarce for it to be valuable to its recipients, and the sample is well balanced between winners and nonrecipients because about half of the agents never received an award. On average, 3.4 awards are presented per month with a minimum of zero and a maximum of 11.

### 2.3 Further Data Information

The data set comprises a total of 1480 id-month observations.<sup>8</sup> Sixty-three percent of the agents in the sample are female, and the agents remain in the sample for 18 months on average.

The call center agents are paid a fixed monthly wage of CHF 4,500 (about \$4,500). The exact sum the individual receives depends on her level of experience, knowledge of languages, and length of employment at the call center. The *Gold Reward* complements the company's salary scheme because it incentivizes activities such as substituting for colleagues or organizing team events that are not remunerated as part of the fixed wage. The management asserted that receiving a *Gold Reward* had no effect on future promotion decisions and award winners did not receive special attention, training, or other advantages, for which we cannot control. Hence, while in-house training presents a positive shock to productivity, it is not correlated with winning awards; therefore, it does not cause systematic biases because they are not correlated with winning an award.

<sup>7</sup>Figure 3 in the Appendix shows the entire frequency distribution of the number of *Gold Rewards* per employee.

<sup>8</sup>The initial data set comprised some additional id-month observations that were lost because one or more performance dimensions were not recorded in a particular month due to vacation, sick leave, or failure of the manager to assess the dimension *Quality*.

### 3 Awards and Performance

#### 3.1 Empirical Specification

To obtain an unbiased estimate of the effect of awards on subsequent performance, one needs a control group of individuals that is identical to those in the treatment group (the group of award winners) in all relevant observable and unobservable factors. Then, the performance of individuals in the control group provides a valid counterfactual for the performance of award winners, and the effect of an award can be estimated as the average difference in performance between individuals in the two groups. Typically, control groups are constructed ex-post via matching procedures (see Angrist and Krueger [1999] for an overview). In our particular case, a *Gold Reward* is directed towards behaviors such as supporting colleagues and organizing team events that are not captured in the core performance rating. This unique feature of our data set suggests that there is no difference in the core performance of award winners and nonrecipients prior to the award. Therefore, we can make the identifying assumption that award winners and nonrecipients of the *Gold Reward* are homogeneous in all factors—other than a fixed effect that we estimate for each individual—that drive core performance prior to winning an award. The quality of this matching (i.e., the validity of our identifying assumption) will be tested as part of the analysis below.

Therefore, to estimate the effect of receiving an award on subsequent performance, we use an event study technique that allows us to estimate period-specific effects both before and after a *Gold Reward* is won.<sup>9</sup>

The following table presents an overview over the three dimensions used to identify and quantify the effect of a Gold Reward on employee performance:

---

<sup>9</sup>A similar technique to study period-specific effects of events was used, for instance, by Greenstone and Moretti (2003) and Peters and Wagner (2008). Event studies have a long history in economics and are used in a variety of settings. An overview is presented in MacKinlay (1997).

Table 1: Dimensions of Identification Strategy

Dimension	Value	Use
Time relative to event	Before bestowal of <i>Gold Reward</i> vs. after bestowal of <i>Gold Reward</i>	Allows testing the homogeneity of winners and nonrecipients with respect to core performance prior to the bestowal of a <i>Gold Reward</i> .
Type of performance	Core Performance vs. behaviors that qualify for a <i>Gold Reward</i> <sup>a</sup>	Ensures exogeneity of event ( <i>Gold Reward</i> ) on core performance (dependent variable).
Treatment	Winner of <i>Gold Reward</i> vs. nonrecipient	Identification of the size of the effect of a <i>Gold Reward</i> on core performance.

<sup>a</sup> The *Gold Reward* recognizes exceptional efforts that are unrelated to core call center duties. Examples of behaviors that qualify for a *Gold Reward* are volunteering as a substitute during vacation times or implementing team events.

Under the identification strategy presented above, the causal effect of receiving an award on employee performance is estimated by fitting the following equation:

$$(1) \quad Y_{it} = \alpha + \sum_{\tau=\underline{T}}^{\bar{T}} \pi_{\tau} W_{i\tau} + \mu_i + \beta X_{it} + \xi_{it}.$$

The dependent variable  $Y_{it}$  represents the performance rating of employee  $i$  in period  $t$ . Because  $Y_{it}$  is constructed as the weighted average of the ratings in the individual performance dimensions discussed above, it takes on many different values and can be treated as continuous (see, e.g., Wooldridge [2002], p. 533). The index  $\tau$  denotes the time period relative to  $t$  and is measured in months.  $\tau$  runs from  $-6$  to  $+6$  and is normalized so that  $\tau = 0$  refers to the current month  $t$ ;  $\tau < 0$  refers to months prior to  $t$ ;  $\tau > 0$  refers to months after  $t$ . The range of  $\tau$  determines the size of the event window. The indicator variable  $\mu_i$  controls nonparametrically for employee fixed effects, such as level of education and gender.<sup>10</sup> Because the resulting panel is unbalanced, the use of dummy variables is preferable

<sup>10</sup>In principle, one could also control for time- and award-specific effects. However, the relative nature of

to fixed effects as controls for individual-specific effects (see, e.g., Greene [1997], p. 623).  $X_{it}$  is a vector of time-varying observable characteristics of the individual, in our case, the length of employment in the call center.  $\alpha$  represents a constant, and  $\xi_{it}$  is a stochastic error term. To calculate standard errors, we cluster on the workgroup level per year.<sup>11</sup> Alternative ways of adjusting standard errors are discussed below.

The key variables in this regression are the  $W_{i\tau}$  indicator variables.  $W_{i\tau}$  equals 1 for a person  $i$  who receives a *Gold Reward*  $\tau$  from  $t$ , and zero otherwise. As the *Gold Reward* is open to all employees in all periods,  $W_{i\tau}$  captures all the relevant information because each employee is either a winner or a nonrecipient in each month. The vector  $\pi_\tau$  are the parameters of interest in this equation and capture the period-specific effects on performance of winning a *Gold Reward*  $\tau$  months from the current time period  $t$  as compared to not winning an award, conditional on all covariates. By including an indicator variable for each period, the effect of being a winner is allowed to vary with  $\tau$ . For example, a coefficient  $\pi_{+2} = 0.5$  means that the performance of employees who won a *Gold Reward* two periods ago is 0.5 points higher than the one of nonrecipients. The time series of the coefficients  $\pi_\tau$  around the event ( $\tau = 0$ ) allows us to detect the causal effect of an award on performance. If the coefficients were significantly positive before the award was presented, there would be concerns about reverse causality. In case the performance of winners and nonrecipients is indistinguishable prior to an award for a large number of periods, we can be confident that our identifying assumption about the homogeneity of winners and nonrecipients holds.

As all individuals are winners or nonrecipients with respect to multiple awards, every

---

our performance measure already eliminates period-specific, exogenous shocks to performance. In addition, the *Gold Rewards* in the individual months that we cover are identical, so there is no reason to expect independent award-specific effects.

<sup>11</sup>We do not have obvious problems with grouped errors as the unit of observation corresponds with the unit of variation, i.e., the award. However, clustering on workgroups accounts for possible correlations of ratings within teams. As team composition varies between years due to employee fluctuation, workgroup-per-year clusters are used. This also increases the number of clusters, which improves inference due to the asymptotic properties of the clustering procedure (Kiefer 1980; White 1980).

performance observation simultaneously helps to identify all 13 different  $\pi_\tau$  from  $\pi_{+6}$ , the performance of winners relative to nonrecipients six months prior to an award, to  $\pi_{-6}$ , the performance of winners relative to nonrecipients six months after an award.

### 3.2 The Performance of Winners and Nonrecipients

Figure 2 shows the average-mean-corrected performance of winners and nonrecipients around the award.<sup>12</sup>

The figure suggests that the performance of winners and nonrecipients is indistinguishable prior to an award and that the performance of winners increases relative to nonrecipients in the period following the award.

This first impression is confirmed in a regression analysis that controls for further factors and accounts for potential serial correlation. Table 2 presents the results when estimating equation (1) for two different subsets of employees. The first model includes all id-months observations with clean event windows. This means that those id-month observations are included where at most one of the winner dummies,  $W_{i\tau}$ , equals one to eliminate confounding effects. Model 2 only includes the id-month observations of those employees that have received at least one *Gold Reward*. As the entire sample is now comprised of *Gold Reward* recipients, our identifying assumption holds per definition because winners and nonrecipients in this sample are homogeneous in their underlying unobservable characteristics. In case the results of model 2 are identical to those of model 1, we can further strengthen our identifying assumption that winners and nonrecipients—even those who never receive an

---

<sup>12</sup>The sample of nonrecipients used to calculate the mean-adjusted performance comprises the performance ratings of those nonrecipients that are in teams with at least one winner in the respective month  $t$ . Excluded are the performance ratings of those nonrecipients that win a *Gold Reward* within six months around  $t$ .

Figure 2: Performance of Winners and Nonrecipients Prior to and After an Award (with 90 percent confidence intervals)

award—are homogeneous.

According to model 1, the performance of winners is 0.24 or 7.4 percent higher than that of nonrecipients one month after the award. This increase is substantial, especially when taking into account the large number of *Gold Reward* winners at the call center and that we use performance in a job dimension that is not incentivized with the award as the dependent variable. Two months after the award, the difference in performance becomes insignificant. Consistent with our homogeneity assumption, we find that, in each of the six months prior to an award, recipients and nonrecipients have very similar performance ratings. Indeed, their performance ratings are statistically indistinguishable for this relatively large number

Table 2: Impact of an Award on Performance (Six Months Before and After the Event)

	Model 1	Model 2
$\pi_{-6}$	-0.055 (-0.54)	-0.069 (-0.67)
$\pi_{-5}$	0.123 (1.37)	0.117 (1.31)
$\pi_{-4}$	0.100 (1.40)	0.098 (1.47)
$\pi_{-3}$	0.076 (0.76)	0.080 (0.84)
$\pi_{-2}$	-0.013 (-0.13)	-0.008 (-0.09)
$\pi_{-1}$	-0.028 (-0.39)	-0.020 (-0.29)
$\pi_0$	-0.034 (-0.51)	-0.022 (-0.33)
$\pi_{+1}$	0.234** (2.73)	0.246** (2.96)
$\pi_{+2}$	0.015 (0.12)	0.035 (0.29)
$\pi_{+3}$	0.172 (1.03)	0.192 (1.19)
$\pi_{+4}$	-0.005 (-0.05)	0.017 (0.17)
$\pi_{+5}$	-0.050 (-0.85)	-0.022 (-0.40)
$\pi_{+6}$	0.005 (0.05)	0.032 (0.28)
<i>Tenure</i>	0.013* (1.76)	0.009 (0.95)
<i>Tenure</i> <sup>2</sup>	-0.000 (-0.98)	-0.000 (-0.81)
<i>Constant</i>	3.209*** (37.29)	3.228*** (34.91)
Observations	1202	667
$R^2$	0.576	0.563

*t* statistics in parentheses

\*  $p < .10$ , \*\*  $p < .05$ , \*\*\*  $p < .01$

of periods. Overall, this finding lends credibility to the identifying assumption that the nonrecipients form a valid counterfactual for the winners. We do find, however, that the fixed effects of winners are, on average, higher than that of agents who never receive an award. While this implies that winners and nonrecipients are indeed not homogeneous with respect to their absolute core performance, they are homogeneous with respect to their core performance once these level effects have been taken into account because of the long time line of insignificant differences in performance prior to the award.<sup>13</sup> Moreover, the results for model 2 closely resemble those of model 1, which further speaks against reverse causation. The control variable *job tenure* does not have a robust statistically significant effect on performance.

RESULT 1. Awards increase the performance of recipients as compared to nonrecipients subsequent to winning.

The same is true when using change in performance as the dependent variable. The winners' performances increase significantly more than the nonrecipients' performances between the month prior to the award and the month after. A closer look at performance in the individual performance dimensions shows that the overall result (i.e., the sizes of the coefficients and their significance levels) is clearly reflected in the *Quality* dimension and, to a lesser extent, in the dimension *After Call Worktime*. Performance also increases in all other performance dimensions, but the effect size and the specific lags that exhibit significant coefficients differ between dimensions and are not strong enough to have a significant

---

<sup>13</sup>In fact, this implies that employees that are productive in terms of the core performance are also the ones that engage in voluntary work behaviors and hence that there is no trade-off between the two kinds of activities. One might counter that awards are given to the productive types not because they actually engage in voluntary work behaviors, but because they collude with supervisors to gain additional compensation for their high performance. However, we can show that within the first five months at the company, employees who receive an award exhibit a higher core performance than those who never receive an award (Mann-Whitney test p-value: .07, one-sided). As employees at the beginning of their careers lack the necessary familiarity with their supervisors and the unwritten rules of the company, this supports the notion that it is in fact the high-performing individuals engaging in voluntary work behaviors rather than low-performing types.

effect on the overall rating. However, these findings should be interpreted with care because only the aggregate rating is a useful measure of performance due to the trade-offs between the different dimensions.

### 3.3 Development of Performance Over Time

Analyzing the performance of winners and nonrecipients over time serves as a check for whether winners increase their performance not only relative to nonrecipients, but also relative to their own performance prior to winning. For the following nonparametric analysis, we use performance ratings that are corrected for individual-specific fixed effects and effect of tenure to make the analysis comparable to the regressions above. Comparing the performance of winners between the month of the award and the subsequent month (i.e., periods  $\tau = 0$  and  $\tau = +1$ ), the one-sided t-test for paired samples suggests that performance is significantly higher ( $\alpha = 0.05$ , p-value: .03) in the month after the award than in the month of the award. In contrast, the performance in the month prior to the award is not statistically different from the one in the month of the award. The average increase in performance between the month prior to the award and the month after the award is 0.16. There is no statistically significant difference in performance between any of these three months for nonrecipients (i.e., between the periods  $\tau = -1$ ,  $\tau = 0$ , and  $\tau = +1$ ). Given that performance is relatively evaluated, that is, in comparison with the average performance in each month, which is driven by the large number of nonrecipients, this insignificance was to be expected. This implies that the observed increase in the relative performance measure for the winners may be driven by nonrecipients lowering their performance. This would be reflected in a deterioration of absolute performance. However, this is not the case. Absolute performance over the four years stays relatively stable. In particular, we do not detect a general trend in absolute performance or any individual performance dimension. In fact, there is a slight increase in absolute performance because quality increases somewhat.

Hence, we can be sure that the observed increase in the ratings of the winners represents higher winner effort.

RESULT 2. Receiving an award improves the performance of winners, whereas the performance of nonrecipients remains unaffected.

### 3.4 Why Do Winners Work Harder?

The observed increase in performance subsequent to winning an award can be attributed to induced feelings of organizational commitment. Akerlof and Kranton (2005), for instance, state that employees who identify with their company perform better and that employers can actively influence whether employees identify with the company. Specifically, initiation rites, such as award ceremonies, can be used to change self-perception.<sup>14</sup> Our evidence, however, suggests that a *Gold Reward* does not cause a sustainable change in preferences (i.e., employee identity) because the effect is limited to the month subsequent to winning. Endocrinological studies suggest that hard-wired mechanisms can raise the performance of award winners. Increases in status caused, for instance, by a victory in a competition have been shown to be associated with a heightened level of testosterone. This in turn increases competitive behavior (Booth et al. 1989; Mazur and Booth 1998). Such effects can be interpreted as preference changes in economics, even though they affect behavior only for a short time after the occurrence of the change in status (i.e., for a number of hours after winning an award). Psychological evidence also suggests that a positive event, which induces a good mood, increases subsequent voluntary behavior when this is in line with the positive cognitions evoked by the event (Isen and Simmonds 1978). At the same time, receiving an award can also induce reciprocal actions (e.g., Fehr and Gächter [2000]

---

<sup>14</sup>According to Akerlof and Kranton (2005), cognitive dissonance (Festinger 1954) is the underlying psychological mechanism that drives this development of loyalty. Applying cognitive dissonance theory to awards implies that individuals, who have publicly accepted an award and thereby the rules and values of the organization, improve their views and valuation of the organization.

or Kube, Maréchal, and Puppe [2008]). According to this theory, winners increase their efforts to reciprocate to the monetary bonus associated with winning the *Gold Reward*. However, it is highly unlikely that the entire effect we document is driven by the monetary bonus. First, the amount is small—only 3 percent of the average monthly salary of around CHF 4,500. Second, field studies have shown that the wage elasticity of workers' outputs ranges from roughly 0.15 to 0.44 (Fehr, Goette, and Zehnder 2008). Thus, the observed increase of 7.5 percent would require a wage increase between 15 to 50 percent. This corresponds to a bonus of between CHF 750 and 2,500, which is much higher than the actual amount of CHF 150. Another explanation for the observed increase in performance may be the increased visibility of the award winner in the month following the award. Recipients may feel a need to live up to the honor of having received an award for their voluntary work behaviors, and this may affect their core performances. This effect should be stronger for award winners whose core performance was below average prior to the award. The data allow us to test this hypothesis by separating the winners into two groups: those individuals who performed below average in  $\tau = 0$  and those who performed above average. Looking at how much performance increases between the month of the award and one month later, we find that, on average, the rating of low performers increases by 0.58, whereas the performance of high performers decreases by 0.17. The one-sample t-test indicates that both coefficients are highly significantly different from zero. This differential impact of winning an award supports the notion that the increase in performance is caused by social pressure or the winners wanting to live up to the award with respect to core performance. At the same time, the differentiated effect renders it highly unlikely that reciprocity or organizational commitment causes the increase because this should apply to under- and over-performing winners in the same manner. However, the differentiated effect could also be caused by mean reversion. Individuals who achieve a very good rating likely

had extreme positive draws from the process generating their output. Their next draws are unlikely to meet or exceed prior realizations, causing their individual performance to revert to the population mean. Therefore, we use a longer time horizon to classify individuals as high- or low-performing. Specifically, we look at  $\tau = +2$ ,  $\tau = +1$ , and  $\tau = 0$ . Individuals that perform worse than average in two or three of those periods are classified as low performers. Low-performing winners increase their rating by 0.29 (which is significantly greater than zero at the 1 percent level), while the rating of high-performing winners changes by 0.03 (not significantly different from zero).<sup>15</sup> Therefore, while there is some mean reversion going on, the differential impact of awards on the rating of high- and low-performing agents is robust.

Arguments rationalizing the observed effect without resorting to social motives unlikely play a role here. The award system is well established and the criteria clear to all employees. Therefore, handing out the award should not change the relevant information of the agents on the type of behavior and the required effort level to win. Further, the small bonus of CHF 150 unlikely changes the opportunity set of the agents or causes an income effect that could explain the result. Moreover, if there were any income effect, it would affect performance in the opposite direction and only strengthen the result that winning the award triggers employees to work harder. A *Gold Reward* has no impact on future promotion decisions, and employees know that. Strategic considerations about trying to win the award again also cannot explain the finding because this would not explain a further increase in performance above the level that was sufficient for winning. Further, if strategic considerations were the motive, the increase should last for more than one period. However, above all, any increase in core performance is by definition of the award criteria not linked

---

<sup>15</sup>The average rating of high performers in the month when they win an award is 3.52 (std. dev. 0.32), which suggests that the performance of high performers is not bounded from above, and they have the scope to increase their performance the same as low performers.

to a higher chance of winning another *Gold Reward* because these reward activities are not captured in the core rating.

We can also rule out that the effect is caused by award winners focusing on those activities that lead to the award at the expense of core performance prior to winning. If the argument were true, the observed increase in performance after the award would only represent a return to the normal level of core performance, and winners and nonrecipients would not be homogeneous despite the similarity of their performance prior to the award. While such an effect could be imagined if one only looked at the three months prior to an award—the maximum time span that an activity eligible for winning lasts—the long time series of insignificant performance differences prior to an award renders the conjecture invalid. In addition, the difference in performance after an award should then also be sustained for more than one month.

Regarding the size of the effect, it is worth observing that the sizes of the documented effects only present a lower bound due to three reasons specific to this study. First, the *Gold Reward* is low in the hierarchy of awards at the company, and one would expect to find even larger effects for the other awards. Second, awards at the company are presented for beneficial behaviors that are not represented in the company's core performance measure, which we use as the dependent variable. Thus, the estimated effect of awards on core performance presents only the spillover effect of the presumably larger effect on those behaviors that are rewarded. One standard objection to award systems is that they induce individuals to exert unproductive efforts to increase their chances of winning. Our result, however, provides evidence to the contrary, as we observe an increase in productive effort. Hence, even if there were some rent seeking going on, it does not come at the expense of productivity. Third, we only measure the impact of the award subsequent to being presented. However, the award system as such does have an incentive effect that, while it

cannot be captured in this study, probably has a substantial impact on the performance of all employees as they work towards the award. In a field experiment, Neckermann and Kosfeld (2008) find that the introduction of an award system increases performance by about 10 percent.<sup>16</sup>

### 3.5 Robustness

The following section addresses a variety of issues concerning the reliability of our results.

As is the case with most, if not all, event studies, our disturbances exhibit serial correlation. However, this issue does not affect our results because we estimate robust standard errors. Specifically, we report the robust (Huber-White sandwich) estimates of variance that provide correct estimates for any type of correlation within the observations of each panel/group. Moreover, Bertrand, Duflo, and Mullainathan (2004) show that, if the intervention variable is not serially correlated, OLS standard errors are consistent, despite the positive serial correlation in the residuals. This holds in our study because the average correlation of the independent variable over time for each individual is close to zero. Serial correlation and heteroskedasticity are more extensively addressed, and additional tests are reported in Appendix C. As a further robustness check we used the two-way cluster approach (Cameron, Gelbach, and Miller 2006), which provides cluster-robust inference when there is two-way clustering that is non-nested. The two dimensions that we checked were id and month because one could imagine errors to be clustered for all observations of one individual and within one month. However, our results are robust to this test as Table 3 in the appendix shows.

We already established above that the direction of causality runs from award to performance by showing (1) that there is no significant difference between the performance of

---

<sup>16</sup>Receiving an award may also have other beneficial side effects that cannot be measured as part of this study. For example, one might conjecture that awards have an additional positive affect on the retention rates of the award winners.

winners and nonrecipients prior to an award and (2) that the results of models 1 and 2 are basically identical. Nevertheless, we additionally tested whether current or lagged performance determines if a person receives a *Gold Reward*. As expected, there is no significant effect of these variables on the likelihood of receiving an award. Only the length of tenure and its squared term have a significant impact, which provides an additional rationale for including these variables in the regressions presented above. Third, the results are robust with respect to the inclusion and exclusion of employees depending on the number of *Gold Rewards* received. The results do not change with a variation in the event window size (we tested event windows ranging from plus/minus 3 to 12 months). In addition, the inclusion of time fixed effects has no effect on the results, which we expected because the relative rating already eliminates any impact of time-varying changes in the business environment. We can also confirm that our result is not driven by the large weight of 50 percent of *Quality* in the index. Using a different index that weights all performance dimensions equally leads to the same pattern of performance, both in terms of the size of coefficients as well as significance levels.

## 4 Conclusion

In general, the use of incentives is indispensable in principal-agent relationships within organizations. Advances in behavioral economics have recently addressed and presented models of a wide set of human motivations such as the desire for status and positive self-image. However, awards as incentive instruments tapping a number of such motives have so far been neglected in economics despite their widespread use in the corporate sector and elsewhere.

This study shows that receiving an award for uncontractible, voluntary work behaviors such as organizing team events or substituting for sick employees increases core perfor-

mance—those efforts that are more immediately linked with business success by 7.5 percent when compared to nonrecipients. To our knowledge, this study is the first to empirically assess the change in behavior induced by the receipt of an award in a principal-agent relationship. This study is unique in that it analyzes performance in a complex work environment—a task that is characterized by many different job dimensions including quality. Specifically, we show in the field that social incentives have a sizeable and robust positive effect on employee performance. Moreover, rewards influence behavior after they have been received, that is, beyond the incentive effect normally considered as people work towards receiving the reward. This clearly contradicts the notion that awards only influence behavior due to their effect on future monetary income and that awards only reflect high ability and performance, but do not cause it. Hence, incentive theory neglects an important part of the value of rewards. Additionally, awards as social incentives have a positive spillover effect on dimensions of the job that they do not target.

Social incentives may turn out to be invaluable in incentivizing types of activities that are desirable for the company, but not contractible. The vague nature of awards, for instance, better corresponds to the vague nature of activities such as helping colleagues or sharing knowledge. Therefore, employees may perceive social incentives to be a more adequate reward for these kinds of activities than monetary bonuses that put a clear dollar value on the exerted effort. Thereby, awards are less likely to reduce intrinsic motivation (see, e.g., Frey [1997]; Bénabou and Tirole [2003] on the crowding out of motivation). At the same time, multitasking problems may less likely occur. Moreover, social rewards may have a positive impact on the work climate and the shared beliefs about appropriate kinds of behavior. There is much scope for future research. One relevant question concerns the optimal number of awards and award categories. Additionally, a deeper understanding of all channels through which awards affect performance might improve our understanding of

incentive provision in principal-agent relationships.

## Appendix

### A. Awards at the Company

#### A.1. The *Thank You* Reward

The *Thank You* reward is exchanged between colleagues. Whenever an employee chooses a colleague for a *Thank You* reward, the recipient immediately receives a notification per email and a letter is sent to her home address. Once a month, the three employees with the highest number of *Thank You* rewards receive gifts (if two employees have the same number of awards, a lottery decides). The first prize is dinner for two (value CHF 200); the second prize is travelers' checks (value CHF 100); the third prize is two cinema tickets (value CHF 40).

#### A.2. The *Gold Reward*

The *Gold Reward* is presented for extraordinary, non-contractual performance with an impact on the output of the whole work group. Each employee can nominate a colleague for a *Gold Reward*. Approval is required by the group manager of the nominated employee. Each *Gold Reward* is accompanied by a certificate for the wall as well as a bonus between CHF 100 and CHF 250 (\$100 and \$250). The reward is presented by the call center manager in front of the other team members. Additionally, the names of the winners are published on the intranet and listed in the monthly company newsletter, and the winners receive a trophy, which has their names engraved on it.

### **A.3. The *Platinum Reward***

The *Platinum Reward* is handed out (1) for exceptional efforts benefiting the whole department or (2) for extraordinary performance over an extended period of time. Moreover, the behavior of the winner must clearly represent the values of the organization. Special attention is given to actions that further cooperation and collaboration across departments. As is the case with a *Gold Reward*, colleagues nominate individuals for a *Platinum Reward*. Both the department head as well as the supra-departmental reward committee have to approve the nomination. The *Platinum Reward* is presented by the human resources manager and comes with a bonus of between CHF 300 and CHF 750 (\$300 and \$750) and a trophy. The names of the winners are published on the intranet, listed in the monthly company newsletter, and additionally mentioned at the yearly Christmas ceremony. The *Platinum Reward* is presented much less frequently than the *Gold Reward*. Between 2004 and 2007, it was awarded to only seven employees in the call center. In general, call center employees have little scope to affect the performance of the whole department or to establish and foster cooperation between the departments. Hence, they have only limited opportunities to qualify for a *Platinum Reward*.

### **A.4. The *President Reward***

The nomination and approval procedure for the *President Reward* is identical to the one described for the *Platinum Reward*. However, this award requires the CEO's approval. The *President Reward* requires efforts that have benefited the company as a whole. As only a few activities meet this requirement, there are only a few *President Rewards* each month. Examples of actions that qualify for the *President Reward* are process innovations that save costs or discoveries of major credit card frauds. The *President Reward* comes with a trophy and an amount between CHF 1,000 and CHF 2,000 (the amount is about the same

in US\$). The names of the winners are published on the intranet, listed in the monthly company newsletter, and additionally announced at the yearly Christmas ceremony.

#### **A.5. The *Employee of the Month***

Each month, a committee chooses one of the *Platinum* and *President Reward* winners of the previous month as the *Employee of the Month* (*Gold Reward* winners are also considered when there are too few *Platinum* and *President Reward* winners). The title is awarded to that *Platinum* or *President Reward* winner who made the most significant contribution, in particular, a contribution that affects the success of the organization as a whole. The nomination requires approval by the CEO, and the award is presented by the human resources manager, often together with the CEO. The award comes with the privilege of using a company mini Cooper (including gasoline) in the respective month and a trophy. Between 2004 and 2007, five call center agents were awarded this title. An email containing a picture of the winner notifies all employees of the new *Employee of the Month*. In addition, the CEO mentions all *Employees of the Month* winners and shows their pictures at the yearly Christmas celebration.

*Gold*, *Platinum*, and *President Rewards* can be won multiple times by each call center agent and can be awarded to multiple employees in the same month. There is only one *Employee of the Month* per month, and this title can be awarded to the same individual only once per calendar year.

#### **A.6. The *Employee of the Year***

At the end of each year, the reward committee and the CEO choose an *Employee of the Year* from among the *Employee of the Month* winners. The title is awarded to that *Employee of the Month* whose contribution benefited the company the most. The title is awarded at the yearly Christmas ceremony and comes with a trophy as well as a week of paid vacation in a summer cottage for up to six people including a generous allowance.

## C. Serial Correlation and Heteroskedasticity

### C.1. Further Discussion

With these kinds of event studies, one might worry about serial correlation and heteroskedasticity of the disturbances, despite the fact that this issue is rarely addressed. This would render the least squares estimator inefficient and even inconsistent if the regressors contain lagged dependent variables. Standard test statistics, such as the first-order autocorrelation coefficient of the residual (coefficient 0.125, significant at 1 percent level), obtained from regressing performance on individual characteristics (*tenure* and *tenure*<sup>2</sup>) and individual fixed effects, as well as the DW-statistic for panel data, do indeed suggest that disturbances are positively correlated.<sup>17</sup> Serial correlation is also detected when using the Wooldridge test for autocorrelation in panel data (Wooldridge 2002, pp. 282–283) (p-value: .05 for  $H_0$ : no first-order autocorrelation). We also ran the modified Wald test for

<sup>17</sup>Second- and third-order autocorrelation coefficients are small (0.028 and 0.004) and insignificant.

group-wise heteroskedasticity on the fixed effect model and found a highly significant test statistic. Therefore, we reject the null hypothesis that the panels in our model have common disturbance variances and that those disturbances are not correlated with the regressors. Hence, adjustments need to be made. If the goal were to estimate a model with complete dynamics, we needed to respecify the model because strong serial correlation is often an indication of omitting important explanatory variables or functional form misspecification. However, as this was not our goal, we had to find a way to carry out statistical inference in light of this positive correlation and potential heteroskedasticity (Wooldridge 2002, p. 402; Li and Hsiao 1998).

Bertrand, Duflo, and Mullainathan (2004) discuss serial correlation as a frequent problem, typically caused by the use of a fairly long time series, the positive serial correlation in the dependent variable, and the high degree of persistence of the intervention variable. They used Monte Carlo simulations to investigate how several estimation techniques helped to solve this serial correlation problem. They found that allowing for an unrestricted covariance structure over time within groups, with or without making the assumption that the error terms in all states follow the same process, worked well when the number of groups (i.e., units to which the intervention is applied, here: individuals) was greater than 50. This is satisfied in our sample. In addition, we allow for an arbitrary variance-covariance matrix as we cluster on the team level. Specifically, clustering implies that the model is estimated by OLS applying the robust (Huber-White sandwich) estimates of variance. These variance estimates are robust in the sense of providing correct coverage rates to much more than panel-level heteroskedasticity (when only panel-level heteroskedasticity is present, a GLS estimation would be more efficient; otherwise, the GLS estimates are incorrect). In particular, they are robust to any type of correlation within the observations of each panel/group. Moreover, Bertrand, Duflo, and Mullainathan (2004) show that, if the intervention vari-

able is not serially correlated, OLS standard errors are consistent, despite the positive serial correlation in the residuals. This is true in this study where the average correlation of the award variable over time for each individual is  $-.05$  (correlation coefficients vary between  $-.31$  and  $.47$  with a mode and median of  $-.05$ ).

To further check the robustness of the reported standard errors, we recalculated them according to other methods suggested in the literature. In particular, we applied OLS with panel-corrected standard errors (PCSE) assuming heteroskedastic and contemporaneously correlated disturbances across panels (a method initially suggested by Beck and Katz [1995]). Analogous to the clustering approach presented above, applying OLS with PCSE errors provides consistent, but inefficient estimates in the face of heteroskedastic and correlated errors. In some sense, the PCSE approach is the opposite to the clustering approach because it allows for correlation among observations at the same period and in different panels, but only for certain types of within-panel correlation, here AR(1). The estimates that were calculated with the Prais-Winsten FGLS (Prais and Winsten 1954) assuming an AR(1) process in the disturbances, do not differ in any meaningful way from the ones presented above. The same holds, when we apply the Driscoll and Kraay standard errors for fixed effect models (Driscoll and Kraay 1998). These standard errors are robust to general forms of cross-sectional (spatial) and temporal dependence when the time dimension becomes large. Because this nonparametric technique of estimating standard errors places no restrictions on the limiting behavior of the number of panels, the size of the cross-sectional dimension in finite samples does not constitute a constraint on feasibility—even if the number of panels is much larger than  $T$ . Hence, we are confident that the standard errors reported in the table are accurate.

## C.2. Regressions With Two-Way Clustering

Table 3: Models with One-Way (Team-Month Basis) and Two-Way (Id and Month) Clustering

	Model 1a one-way	Model 1b two-way	Model 2a one-way	Model 2b two-way
