Africa Region Population Projections

1989-90 Edition

Rodolfo A. Bulatao,
Eduard Bos,
Patience W. Stephens,
and My T. Vu

The population of the Africa region is growing faster than the population in any other region. It should double in a little more than 20 years.

Policy, Planning, and Research

WORKING PAPERS

Population, Health, and Nutrition

The majority of populations in the Sub-Saharan Africa region are growing rapidly. In some countries, where the average woman continues to have seven or more births, growth is as rapid as 4 percent a year. The population of the region as a whole is likely to double in slightly more than two decades, and slightly more than two decades after that, the region will be contributing more to annual world population growth than the far larger Asia region.

As a consequence of high fertility, populations are young and dependency ratios are very high, up to three times world minimums. Linked with high fertility are high levels of mortality: in some countries, life expectancy at birth is barely 40.

The region will require a long transition, perhaps centuries, before population becomes stationary. At that point, the region could have six times its present population.

This paper is a product of the Population, Health, and Nutrition Division, Population and Human Resources Department. Copies are available free from the World Bank, 1818 H Street NW, Washington DC 20433. Please contact Sonia Ainsworth, room S6-065, extension 31091 (256 pages with tables).

The PPR Working Paper Series disseminates the findings of work under way in the Bank's Policy, Planning, and Research Complex. An objective of the series is to get these findings out quickly, even if presentations are less than fully polished. The findings, interpretations, and conclusions in these papers do not necessarily represent official policy of the Bank.

PREFACE

Population projections for all countries are prepared annually by the Population and Human Resources Department of the World Bank. They are published first in summary form in the Bank's *World Development Report* and later in greater detail as technical notes or working papers and, in alternate years, as a separate book.

This set of projections was prepared for *World Development Report 1989*. It appears for the second time in the Policy, Planning, and Research (PPR) Working Papers series. The tables will also be published shortly, somewhat differently organized, in book form.

As was done last year, separate working papers cover each of the Bank's four regions: Africa (sub-Saharan); Asia (and Oceania); Europe, the Middle East, and North Africa (including the U.S.S.R.); and Latin America and the Caribbean (and Northern America). Combined, these papers cover all countries of the world.

The data format of these papers generally follows the previous edition and is consistent in the demographic indicators provided, except for minor changes, with the series of preceding reports.

We intend these papers to provide a convenient and up-to-date reference on the likely demographic future of each country, to facilitate the Bank's work of assisting them in planning more productive futures. We welcome comments on their utility, and how this might be enhanced.

Anthony R. Measham
Chief
Population, Health and Nutrition Division

ACKNOWLEDGEMENTS

A number of persons provided us with important information for this work or assisted us in preparing it in other ways. The Estimates and Projections Section of the U.N. Population Division has been continually supportive in providing us with data, even before their publication as U.N. assessments. Partly as a result, nonessential differences between these projections and the biannual U.N. assessments have been minimized. We are grateful to the former acting section chief, Shunichi Inoue, and to his continually accommodating staff, as well as to the head of the division, Jean-Claude Chasteland, and hope that the collaboration will continue.

World Bank country economists, population specialists, and the few demographers in the operating divisions have also provided us with recent population estimates, bringing to our attention government reports we might not otherwise see.

This exercise was carried out using a personal computer program, ProjPC-II, written by Kenneth Hill of Johns Hopkins University.

Both the Population, Health, and Nutrition Division and the Population and Human Resources Department have been supportive of this work, despite the time required. We are grateful to the division chief, Dr. Anthony R. Measham, and the department director, Ann O. Hamilton.

We also wish to acknowledge the interest of the Bank's International Economics Socioeconomic Data Division (IECSE), which not only utilizes our figures--for such important Bank purposes as estimating per capita GNP--and incorporates them into the databases it maintains and publications it distributes but also helps coordinate communications with country economists. Sulekha Patel of that division has been particularly helpful in the past year.

In producing the manuscript, Inga Schweiger was responsible for some typing and coordinating the paper flow.

INTRODUCTION

Population projections are reported here for the individual countries comprising one of the four World Bank regions. Companion papers in this series report projections for each of the other regions. Each paper also reports population summaries for various geographic regions and income groups.

This introduction (included, for convenience, in each paper of the series) explains what projection results are provided in the detailed tables; describes the base data and the projection methodology, which has been revised since the last edition of these reports; and summarizes and interprets the main results.

Caution is appropriate with projections like these. They essentially involve working out the implications of assumptions (to be discussed shortly) about particular demographic parameter levels and trends. None of the descriptions of results below should be read as indicating certitude about the future. Instead, they should be read with the universal qualifier that population will follow the indicated path if the assumptions prove to be correct.

PROJECTION RESULTS

The projections cover almost two centuries, from 1985 to 2150. With data available as of mid-1989, separate projections were prepared for 187 countries, economies, territories, or small-country groupings, covering the entire world. The length of the projection period was chosen to allow populations to approach stability, which for several takes essentially the entire period.

Only one projection is reported per country, economy, territory, or group. Other projection exercises sometimes provide high and low options. Instead of alternative projections, we choose to give only our best estimate of the likely demographic future but to update this annually. Approaches to defining high and low options are described in the methodology section for those interested in implementing them.

The detailed projection tables following this introduction contain two pages for each country. The first page gives projection results for every five years between 1985 and 2030, with population figures for years ending in 0 or 5 and demographic indicators for the intervening quinquennia. This information is provided:

- Population by sex and five-year age groups, in thousands
- Birth rate, death rate, and net migration rate per thousand
- Rate of natural increase and population growth rate in percent
- Total fertility rate (TFR) and net reproduction rate (NRR)
- Expectation of life at birth (e_0) and at age ten (e_{10}) in years
- Infant mortality rate (IMR) per thousand, and probability of dying before age five (q_5)
- Dependency ratio (for exact years rather than quinquennia).

The second page adds results for every 25 years from 2000 to 2150 (as well as rates for the 1985-2000 period). This page provides fewer indices, including only the population by age and sex, the birth, death, net migration, and growth rates, total fertility, life expectancy, and infant mortality.

DATA AND METHODS

The key elements in these projections are base-year (mid-1985) total population estimates and age-sex structures, base-period (1985-90) mortality, fertility, and migration rates, and assumed trends in the rates. These elements will each be described. New data have been incorporated since the previous edition; an appendix to this Introduction indicates the sources for all base-year or base-period estimates. Revised methodology for projecting vital rates is described and some of the relatively modest effects of the revision shown.

Total Population and Age-Sex Composition

Estimates of the total population in mid-1985 are obtained from the most recent reliable sources. Where possible these are recent censuses, with appropriate adjustments for underreporting, projected to mid-1985. A number of such estimates made by the United Nations (U.N.) Population Division (in *World Population Prospects 1988*) have been adopted. (Prepublication versions of the estimates were generally used.) For countries with dated or unreliable census data, other official estimates may be taken, often from the U.N. *Population and Vital Statistics Report* and occasionally from government publications. Other sources of estimates include Eurostat (1987) and the United States Bureau of the Census (1985; Jamison, Johnson, and Engels 1987). The specific sources of information are listed by country in the appendix.

The mid-1985 population of each country is distributed by age and sex using a percentage distribution often obtained from *World Population Prospects 1988*. These distributions were estimated by the U.N. Population Division from census data adjusted for age misreporting or using stable population analysis. For most Sub-Saharan countries, World Bank estimates of current age-sex distribution were adopted instead.

Mortality Level and Trend

This section considers the sources of mortality data used for the base period and the manner in which future trends in mortality are defined. Future trends are specified through projections of life expectancy by sex, projections of infant mortality, and the choice of appropriate model life tables. Each of these elements will be described. Comparisons will also be made with the previous method for projecting mortality.

Data. Base-period mortality levels in the projections are represented by life expectancies by sex and infant mortality rates for both sexes combined. Life expectancies were obtained from a variety of sources. A preliminary version of *World Population Prospects 1988* was a common source. Other figures are based on official or other estimates appearing in *Population and Vital Statistics Report* or government publications. A few figures are taken from the U.S. Bureau of the Census (1985; Jamison, Johnson, and Engels 1987), Eurostat (1987), and Monnier (1988). These sources often report mortality levels for periods other than 1985-90, or give indices other than life expectancies, or both. Some estimation and projection is then necessary to obtain the right index. In some cases, a mortality estimate is first made for an earlier period, and an estimate for 1985-90 obtained by applying the projection methodology being described here. Some Bank sources are also cited in the appendix: Bank sector reports; Bank assessments, involving unpublished analysis of census or survey data; and Bank estimates, or informed judgments for which no further source can be cited.

Infant mortality rates come about as often as life expectancies from the preliminary version of *World Population Prospects 1988*. However, a number are drawn from *Population and*

Vital Statistics Report and others are estimated from diverse data.

Future trends in life expectancy. Life expectancy is projected from year 0 to year t using a logistic function over time of the form

$$e_t = k_0 + k / \{1 + \exp [\text{logit}(e_0) + rt]\}, \quad \text{with} \\ \text{logit}(e_0) = \log_e [(k_0 + k - e_0) / (e_0 - k_0)].$$

The logistic function is set to rise most rapidly from a level of 50 years or so and increasingly slowly at higher levels. The minimum (k_0) for the logistic functions for both sexes is assumed to be 20 years, and the maxima ($k_0 + k$) are assumed to be 82.5 years for females and 75.8 years for males. The rate of change (r) for the logistic function is allowed to vary across countries, and for a given country to vary over time.

For the first quinquennium (1985-90), the rate of change (r_1) is estimated from the rate of change in the previous quinquennium (r_0) and from the female secondary enrolment ratio (s_0), using the equations

$$r_1 = .00379 + .723 r_0 - .000254 s_0 \quad \text{for females, and} \\ r_1 = .01159 + .885 r_0 - .000318 s_0 \quad \text{for males.}$$

Percent urban is used in a few cases, with a different equation (see Bulatao and Poff 1989), where secondary enrolment is not available, and in fewer cases still the rate of change in the previous decade is used instead of the rate of change in the previous quinquennium when the latter appears to have been affected by exceptional circumstances. Limits are imposed on the rate of change for the first quinquennium (and for all other quinquennia), such that it cannot be greater than -.017 (which would give slow mortality decline) or less than -.053 (which would give rapid mortality decline).

For the second quinquennium, the rate of change is estimated as a function of the rate of change for the first quinquennium:

$$r_2 = -.007 + .8 r_1.$$

The rate of change for the third quinquennium is estimated from the rate of change for the second quinquennium in the same manner. This equation allows rates of change to converge toward the uniform pattern imposed for subsequent quinquennia.

For these subsequent quinquennia for all countries, the rate of change in life expectancy is constant at -.035 for both sexes. At this rate, the annual increments to life expectancy vary by initial levels as indicated by the medium pattern in Table 1. Minimum and maximum increments corresponding to the slow and rapid limits imposed on rates of change in the first three quinquennia are also shown.

Future trends in infant mortality. Infant mortality is projected using a similar logistic function. The rate of change for each of the first three quinquennia is obtained from the equation

$$r_t = .03 + .5 r_{t-1},$$

with the restriction that this rate must be in the range [.024, .130]. These limits provide schedules of minimum and maximum annual decrements to infant mortality, varying by the initial rate, shown

in Table 2. A set of medium decrements is also provided, representing the typical schedule of improvements toward which rates of change converge when the preceding equation is applied successively.

Selection of life tables.

Those life tables are selected from the Coale-Demeny models (Coale and Demeny 1983) that provide the projected life expectancy and infant mortality rates for the first three quinquennia. First, a level of the life tables is chosen to give the desired infant mortality rate (interpolation is used if necessary). Mortality rates up to age 14 are taken from this life table. Second, another level of the life table is chosen to give rates for ages 15 and older such that the desired level of life expectancy is obtained. Among the four Coale-Demeny families (North, South, East, and West), that family is chosen which minimizes the divergence between the two chosen levels.

For subsequent quinquennia, only life expectancy is used in determining levels, and the West family is used consistently.

Survivorship ratios from these model life tables were specified for the first three quinquennia and for 2025-30, 2050-55, and 2100-05. The projection program used, ProjPC-II (Hill n.d.), was allowed to interpolate linearly for intervening periods, to facilitate a smooth transition across life table families where this was necessary.

Comparison with other mortality projections. These procedures may be compared with the previous procedures with regard to their rationale and to their effects on projected mortality and population. The change in procedures does produce generally minor, expected differences in results.

These procedures were developed from analysis of trends in life expectancy and infant mortality in available national data (Bulatao and Bos 1989). Logistic functions are used because these fit past trends best, country by country. The schedules of medium change in life expectancy and infant mortality reflect median trends across countries, and the schedules for minimum and maximum change reflect the 10th and 90th percentile when country trends are ranked from slowest to fastest. The equations to predict short-term trends in life expectancy and infant mortality were estimated using these data; other socioeconomic factors, like per capita income, did not improve prediction.

The procedures used for projecting mortality in the previous edition were based on earlier data and involved two separate schedules of increments to life expectancy, for countries with high and with low female primary enrolment. Infant mortality was not projected separately, and life tables were chosen based on life expectancies alone.

Table 1 Assumed Annual Increments to Life Expectancy (in years)

Initial life expectancy	Males			Females		
	Minimum	Medium	Maximum	Minimum	Medium	Maximum
40	0.22	0.45	0.69	0.23	0.48	0.73
45	0.23	0.48	0.73	0.26	0.53	0.80
50	0.24	0.48	0.73	0.27	0.55	0.83
55	0.22	0.45	0.69	0.26	0.54	0.81
60	0.19	0.39	0.59	0.24	0.50	0.76
65	0.15	0.30	0.45	0.21	0.44	0.66
70	0.09	0.18	0.27	0.17	0.35	0.52
75	0.01	0.03	0.04	0.11	0.23	0.34
80	--	--	--	0.04	0.08	0.12

-- not applicable.

The current schedule of medium increments to life expectancy is compared with the previous schedule for high-enrolment countries, as well as with the medium schedule used by the U.N. (1989), in Figure 1. (Only female life expectancy is shown.). The three schedules are close to each other, the main difference occurring at high levels of life expectancy, where the U.N. permits substantially more improvement. Given the long-run nature of these projections, the current schedule cannot permit rapid improvements at high levels without either higher maxima or an abrupt slowdown in improvements at some future point.

A similar comparison is made in Figure 2 of decrements to infant mortality. Neither the previous procedures nor the U.N. procedures are based on explicit schedules for infant mortality change. To allow comparison, actual decrements were calculated from country projections and curves were fitted to represent their dependence on initial level of infant mortality. Figure 2 shows that the medium decrements are generally larger than those implicit in previous World Bank and current U.N. projections (though never by more than one per thousand), possibly reflecting recent, more rapid improvements captured by the revision in methodology.

In addition to the new schedules, the current procedures involve some individualization of country trends. The effects of this are more difficult to assess. Bulatao and Bos (1989) report simulations for eight countries with widely varying mortality levels, which provide some impression of the changes. For these eight countries, the new projected trends for life expectancy generally remain close to trends projected by the previous procedures, as well as to trends projected by the U.N. The main differences are in two areas. First, for countries like Norway, the current and the previous procedures agree, but the U.N. projects faster improvements, following their schedule shown in Figure 1. Second, for countries like Ghana and Bolivia, the slowness of past improvements in life expectancy is reflected in projected levels that, after two or three decades, are as much as but no more than 4-5 percent lower than those previously projected.

Infant mortality trends differ more than life expectancies from those previously produced, because the previous procedures relied on models to give infant mortality levels. The new estimates of future infant mortality are sometimes lower and sometimes higher than the previous estimates, with no consistent pattern.

The simulations showed that the crude death rate is affected by these changes, rising or falling as much as 10 percent relative to previous estimates for specific periods. On the other hand, total population is affected much less, varying from previous estimates for future periods by 2.5 percent at most.

Fertility Level and Trend

After briefly describing the sources of fertility data, this section explains how future trends in fertility are determined. It then considers how the procedures compare with previous

Table 2 Assumed Annual Decrements to Infant Mortality Rate (per thousand)

Initial infant mortality rate	Minimum	Medium	Maximum
150	-0.90	-2.26	-4.97
140	-1.00	-2.51	-5.52
130	-1.08	-2.71	-5.92

Figure 2 Annual Decrements to Infant Mortality Rate (per thousand), by Initial Rate, Compared with the U.N. and Previous World Bank Patterns

procedures for projecting fertility.

Data. Base-period total fertility rates (TFRs) are derived from the same mix of sources as mortality rates, including *World Population Prospects 1988*; official sources, as cited in *Population and Vital Statistics Report* or in government publications; the U.S. Bureau of the Census (1985; Jamison, Johnson, and Engels 1987); and Monnier (1988). We also relied on various surveys, especially Demographic and Health Surveys, which were available for two dozen countries. Often, these sources give fertility estimates for a different period or in terms of the crude birth rate, and appropriate total fertility rates were obtained by projection of earlier estimates or approximated using available data on age-sex composition and age-specific fertility. The appendix lists the specific source for each country, and also indicates some cases where an informal Bank estimate was made in the absence of reliable data.

Future trends. Future fertility trends are specified by quinquennial total fertility and by a year when the net reproduction rate reaches unity, i.e., when the average woman's fertility results in exactly replacing herself. (This is referred to here as the replacement year.) Separate procedures are applied for three stages of the fertility transition: the pretransition stage, when fertility is high and sustained fertility decline has not started; the transition stage, when fertility is high to medium and sustained fertility decline is in progress; and the late-transition and posttransition stage. We discuss procedures for determining total fertility in each stage and then explain what age-specific patterns of fertility were applied.

For current purposes, a fertility transition is assumed to have started if a country has experienced a drop in total fertility of at least .5 points over any five-year period, or if total fertility is already below 4.5 after a more gradual decline (Bulatao and Elwan 1985). The pretransition stage is the stage before any such decline is evident. The late-transition and posttransition stage is defined by a total fertility rate one point above replacement level (about 3.15) or lower.

Countries in the pretransition stage are assumed to start a fertility transition in the quinquennium after combined male and female life expectancy reaches 50 years, but in no case later than 2005. The life expectancy threshold is slightly lower than the threshold of 53 years previously shown to be a universal precondition, though not a sufficient condition, for the start of fertility transition (Bulatao and Elwan 1985). Until a transition starts, total fertility is assumed to be constant. The one exception is where sterility is a significant factor; sterility is then assumed to decline linearly to 6 percent over three quinquennia, with each percentage point drop in sterility raising total fertility by .11 points (Frank 1983).

In the transition stage, the rate of fertility decline is based on the rate in the preceding quinquennium, assuming transition had already started in that period. With previous annual change represented by D_{TFR} , annual change during the transition is set at $(-.05 + .5 D_{TFR})$. However, limits are set on this change: it must be at least -.073 points and at most -.210 points, which may be taken to define slow and rapid fertility decline. (Previous analysis in Bulatao and Elwan 1985 defined rapid decline as an annual total fertility change of -.2164 points, which is consistent.) If the formula does not apply because transition has just started, an average annual decline in total fertility of .102 points is imposed. Figure 3 shows the patterns of fertility decline implied by this average and by the slow and rapid limits. In the early part of the transition stage, the sterility adjustment is applied if appropriate to raise total fertility slightly.

In the late-transition and posttransition stage, fertility approaches replacement level, either from slightly above or slightly below it. Four alternative patterns, represented in Figure 4, are applied in this stage.

Figure 3 Assumed Medium Trend and Alternative Slow and Rapid Trends in Total Fertility During the Fertility Transition

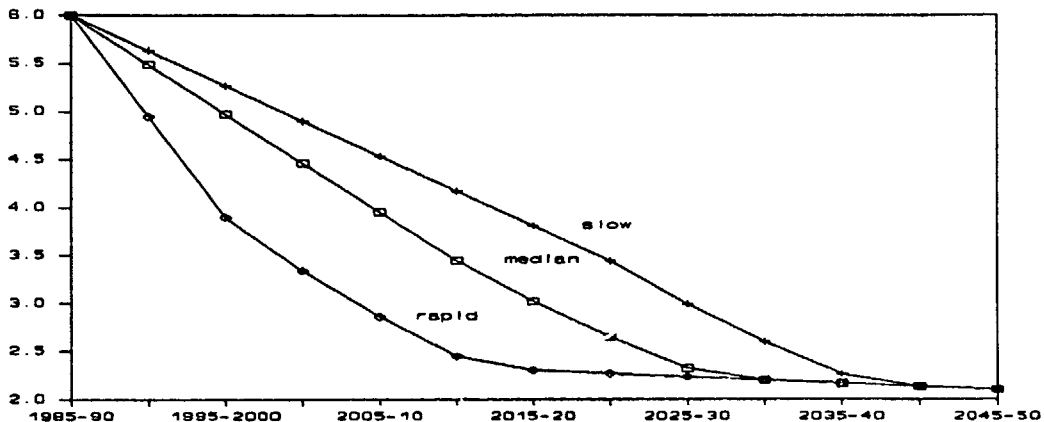

Figure 4 Assumed Trends in Total Fertility at the End of the Fertility Transition

Figure 5 Percentage of Total Fertility Assigned to Different Ages, by Level of Total Fertility

- Generally, a geometric function is imposed on total fertility, decline from one point above replacement level to replacement level, with this decline assumed to take 15 years.
- Where total fertility has shown unusually slow decline, it is assumed to take 20 rather than 15 years for total fertility to fall one point to replacement.
- Where, toward the end of a fertility transition, total fertility is still recording rapid declines even though it is close to or even below replacement level (2.25 to 1.75), it is assumed to fall further for one period, generally going below replacement, to stay constant in the next period, and then to return to replacement.
- Where the transition has been completed and total fertility is below replacement, it is assumed to stay at the current level for two quinquennia, and then to return gradually to replacement, along a linear path, by 2030.

In applying late-transition procedures, the level of total fertility that provides replacement is approximated by a quadratic formula based on female life expectancy ($e_{(t)}$) in the replacement year:

$$TFR_{NRR=1} = 6.702 - .1107 e_{(t)} + .0006592 e_{(t)}^2.$$

The replacement year is first approximated in order to determine life expectancy and then calculated given this formula and whichever pattern of fertility change above is appropriate.

For all stages of fertility transition, the age pattern of fertility is determined in the same fashion, depending on the level of total fertility (Figure 5). Two basic schedules of age-specific fertility are defined: for total fertility levels greater than six and for total fertility levels of three and lower. In between, age patterns are obtained by interpolation between the two schedules. At a total fertility level of six, a greater proportion of births are at younger and older ages of the reproductive span, and the mean age of childbearing is 28.9 years. At a total fertility level of three, births are concentrated in a narrower band of ages, and the mean age of childbearing is 28.0.

Comparison with other fertility projections. These procedures contrast with the procedures previously used, which depended essentially on subjective judgments of the replacement year for each country. We explain some of the basis for the procedures and contrast the results.

These procedures were developed from analysis of total fertility trends in cross-national data (Bos and Bulatao 1989). In the pretransition stage, countries showed mostly stable fertility. The transition stage was more interesting. Across 42 countries which started a fertility transition between 1955 and 1983, the average annual decline in total fertility ranged from 0.06 to 0.25 points. Countries which had initial sharp declines in fertility tended to continue declining rapidly, while those that started with more gradual declines continued along the same path. Rapid and slow decline were found in all regions. The rate of decline was predicted best by the rate in preceding periods; socioeconomic factors added little to this prediction. Other than the mortality threshold, socioeconomic factors also failed to predict the start of fertility transition.

The previous procedures involved a regression equation for the replacement year, derived after initial subjective judgments of this year. Reverse geometric and geometric curves were then fit between current fertility and replacement level. By contrast, the current procedures focus on the pace of change in total fertility, determining the replacement year as the outcome rather than the first step in the process.

Comparisons of results are provided for selected countries in Bos and Bulatao (1989). Overall, the new procedures have slight effects on the projected future course of fertility and on projected population. However, they do delay the start of fertility transition relative to the previous procedures in countries with high mortality levels. They also tend to slow fertility decline in Africa, which under the previous procedures was faster than has generally been experienced by countries passing through the fertility transition. These changes have a lasting effect on projected population for the affected countries, which tends to be somewhat higher in the long run. Other smaller effects also exist. For instance, the provision that allows some countries to continue fertility decline below replacement level leads to projections of slightly lower fertility in some parts of East Asia.

Migration Level and Trend

Estimates of net international migrants in the base period, by sex, were made from a review of international migration statistics published by national immigration agencies, statistical organizations, and other official and unofficial sources; from country population estimates and projections produced by international and regional agencies, national census and statistics offices, other government organizations, interagency task forces, and research institutions; and from discussions with experts in the subject (Arnold 1989). These estimates constitute a substantial revision of estimates used in the previous edition, and involve somewhat higher levels of net migration (Table 3).

For purposes of these estimates, individuals are counted as migrants who have resided in countries different from their previous residences for at least a year. An exception is refugees living in officially designated camps, who continue to be counted in their countries of origin regardless of period of residence. Only net estimates by quinquennium were made; immigration and emigration were not estimated separately, and single-year figures were not assessed.

Estimates of future net migrants by quinquennium up to the year 2000 were also made as part of the same examination of data and sources (Arnold 1989). These estimates are strongly affected by official policies and plans in the major receiving countries. The figures were designed to total zero in each quinquennium for the whole world. After the year 2000, the number of net migrants is assumed to approach zero linearly in each country, at the estimated rate of change in their number from the period 1990-95 to the period 1995-2000, or at a rate that would make their number zero by 2025-30, whichever rate is faster. For these later periods, a zero total for worldwide net international migration was obtained by adjusting initial estimates of net migrants in three major receiving countries--the United States, Australia, and Canada--upward or downward as necessary by a proportion constant across these countries, but varying by quinquennium. These adjustments were of 1 or 2 percent for the earlier periods, negligible compared to the volume of migration assumed for these countries, but were up to 10 percent for later periods.

The age-sex distributions of migrants are determined from alternative models based on their sex ratios. If migration is heavily male, migrants are assumed to be concentrated in the age group 15-30, with few children and elderly. If migration is more balanced between males and females, proportionally more migrants are assumed to be children and elderly (Hill n.d.).

The revised migration estimates are higher than the previous estimates, particularly for the near future. In the base period, annual total net moves (i.e., not counting any moves that are balanced by moves in the opposite direction) were 900 thousand in the previous estimates and are 1.1 million in the revised estimates. For the following two quinquennia, the changes are larger, from 630 to 990 thousand moves and from 380 to 890 thousand moves. However, even the largest of these figures is only 1 percent of annual world growth, or the equivalent of annual increase in a single moderate-fertility country like Turkey.

Source: Arnold 1989.

The estimates assign to the United States more net immigrants in 1985-90 than all other countries of the world combined. Other major destination countries are Australia, Saudi Arabia, Canada, and Côte d'Ivoire. Mexico has by far the largest net emigration, and its dominance in this area is expected to increase in the 1990s.

SUMMARY OF RESULTS

A brief discussion of projection results in this section will focus, first, on the population of the world and continents; second, on the population of subcontinental geographic regions and of countries grouped by income; third, on the population in World Bank regions, which differ from the U.N. geographic regions; and, finally, on the population of particular countries or economies.

World and Continents

For the world and the continents, we consider population totals and medium-term growth; long-run growth; age structure and dependency; and the fertility and mortality rates underlying the projections.

World population. The population of the world is estimated at 4.84 billion in 1985. It surpassed 5.0 billion in mid-1987, and is projected to reach 5.3 billion in 1990 (Table 4). The annual rate of growth in 1985-90 has been 1.74 percent. This rate is projected to decline to 1.66 percent in the first half of the 1990s, and to 1.54 percent toward 2000. In spite of this, the annual net increase in the number of people will be larger each year until the late 1990s, averaging

Table 4 Total Population, Annual Increase, and Growth Rates for the World and Less Developed and More Developed Countries, 1985-2025

Year	Population (millions)			Period	Annual increase (millions)			Growth rate (percent)

Oceania	25	42	44	45	1.8	1.3	(a)	2030

Note: "More developed" comprises Europe, U.S.S.R., Northern America (United States and Canada), Australia, New Zealand, and Japan. "Less developed" comprises the rest of the world.

a. Population will not double with projected rates.

Africa is growing much faster, at over 3 percent annually, as opposed to only 1.9 percent for Asia. Africa currently has a smaller population than Asia, Europe and the U.S.S.R., and the Americas, but by the year 2000 will be second in size only to Asia. Annual growth rates in Africa are projected to stay above 2 percent at least up to 2025, by which year the continental population will have almost tripled.

America, with 14 percent of world population, includes both more developed and less developed countries and is growing as a whole more slowly than Africa and Asia. By 2025, its population will have increased by half, but its share of world population will have fallen to 12 percent. The small Oceania group is projected to experience growth essentially similar to America.

Europe and the U.S.S.R., now second in size to Asia, will be only fourth among these continents by 2025. Its share of world population will shrink from 16 to 10 percent. This projection assumes that fertility, currently below replacement level for the group and for many countries, will rise to replacement level by 2030. Should this not happen, the projected 10 percent increase in the population by 2025 could be smaller, or could even become a decrease.

Long-run trends. The long-run implications of the projection assumptions are illustrated in Table 6, which shows projections up to 2100 as well as other indicators. If every country and economy reaches replacement-level fertility by or before 2060, world population will be over 11 billion by the end of the next century. Another 300 million will be added before the population becomes stationary, i.e., before the growth rate falls to zero.

Table 6 shows two ratios, that of the projected stationary population to the 1985 population, and that for population momentum. The latter is the ratio to the 1985 population of

the eventual stationary population under the special assumptions that fertility drops to replacement level immediately, mortality stays constant at current levels, and no migration takes place. (Previous estimates of momentum in *World Development Report* have allowed mortality to decline.) It is effectively an indicator of the amount of future population growth that can be attributed solely to the current age structure of a population. An illustration of the importance of momentum is the fact that more than one billion of the stationary world population will be added because of momentum after replacement fertility is achieved.

Population momentum is considerably lower for more developed than for less developed countries. For more developed countries, only 10 percent growth can be expected because of the age structure. Nevertheless, this will still be the main source of growth for these countries, as indicated by the stationary population being only 10 percent larger than the current population.

Across continents, population momentum is highest for Africa at 1.6, but is clearly only a small part of future growth. The projected stationary African population is more than five times its 1985 population.

Age structure. Of the 4.84 billion people in 1985, 60 percent were in the working ages of 15-64, giving a dependency ratio (of those younger and older combined per hundred members of this group) of 67. By 2025, the world dependency ratio is projected to fall to 53. Children and youth under 15 will have fallen from 34 to 26 percent of the population, while the aged 65 and over will have risen from 6 to 9 percent (Table 7; see Table 19 for percentages).

Projected trends in more developed and less developed countries are quite different. In more developed countries, the number of children and youth will actually decline from 260 to 248 million, and as a proportion of the population they will fall to only 19 percent. The aged, on the other hand, will almost double, and by 2025 should be almost as numerous as children and youth. Thus, the dependency ratio in more developed countries will rise from 50 to 58.

In less developed countries, children and youth will continue to increase, from 1.4 to 1.9 billion, though as a proportion of the population they will fall from 37 to 27 percent. The aged, who are far fewer, will be increasing much faster, from 153 to 514 million, or from 4 to 7 percent of the population. The dependency ratio will fall from 71 to 52, as the working-age population also grows very fast, at a 2.3 percent annual rate up to 2000 and at a 1.7 percent rate from 2000 to 2025.

These contrasts are summarized in four population pyramids, for more developed and less developed countries for 1985 and 2025 (Figures 11-14). The pyramids for the two groups of countries are drawn to different scales. For more developed countries, growth will be modest and mainly involve the pyramid becoming increasingly rectangular. For less developed countries, all age groups will increase, but, given previous high fertility and high infant and child mortality and expected declines in these parameters, the pyramid will become bulkier in the middle, among working-age adults.

Across continents, Africa stands out with 45 percent of its population--10 points more than any other continent--under 15. Consequently, Africa has a dependency ratio of 94, as opposed to only 57-66 in Asia, America, and Oceania and only 51 in Europe and the U.S.S.R. All three age groups--the young, those of working age, and the aged--will grow considerably faster between 1985 and 2025 in Africa than anywhere else. The older age groups will grow somewhat faster than the younger age groups in Africa, as will also be true in all other continents. However, by 2025, those under 15 will still be 36 percent of the population of Africa, as opposed to 19-25 percent of the population of other continents.

Note: "More developed" comprises Europe, U.S.S.R., Northern America (United States and Canada), Australia, New Zealand, and Japan. "Less developed" comprises the rest of the

Fertility and mortality. Underlying these projections are fertility and mortality rates summarized in Table 8 for the world, less developed countries, and more developed countries. (Rates for continents are in Table 12.) The expected reduction in the world population growth rate of .2 percentage points in the next decade is based on simultaneous reductions in the crude birth rate of 3 points per thousand and in the crude death rate of 1 point per thousand, the bulk of these reductions taking place in less developed countries. The crude birth rate in less developed countries, 31 per thousand (double the rate in more developed countries), will decline 4 points per thousand in each of the next two decades. In more developed countries this rate will decline at a considerably slower pace. The crude death rate, on the other hand, is actually lower in less developed countries, with their younger populations, than in more developed countries, and will decline in the former while it rises in the latter.

Unlike the crude birth rate, the total fertility rate is not affected by differences in age structure. This rate for the world as a whole, estimated at 3.4 for 1985-90, will fall 1 percent a year until 2000 and .8 percent a year between 2000 and 2025. The decline will be almost entirely in less developed countries, where total fertility will go from 3.9 in 1985-90 to 3.1 in 2000-05 to 2.5 in 2020-25. In effect, the average woman in less developed countries will have one-and-a-half fewer children in 2025 than in 1985. These declines may appear relatively moderate. However, given that fertility is unlikely to decline much further in China and a few other large countries, the reductions required in other countries will still be fairly substantial. For instance, for Africa a substantial reduction in total fertility from 6.1 to 5.1 is expected within 15 years, and an even larger reduction to 3.3 within the following 20 years. Such reductions are possible, on the basis of past experience with fertility transition, but in the recent past have not happened automatically but required

Note: Crude birth rates (CBR) and crude death rates (CDR) are per 1000 population; total fertility rates (TFR) are per woman 15-49 years of age; life expectancy at birth, e(0), is given in years; and infant mortality rates (IMR) are per 1000 live births. (See definitions in World Bank 1989.)

deliberate intervention to lower fertility.

Figures 15 and 16 show that these assumptions about total fertility are close to those used by the U.N. and those used in the previous edition of these projections. Estimates of current fertility agree across the different projection exercises. For less developed countries, the current assumed trend initially matches the previous trend, and then slows down relative to it. This slower decline takes into account evidence that fertility changes slowly, even when transition has started, in regions like South Asia. For more developed countries, the current trend allows fertility to stay below replacement longer than the previous trend or the U.N. trend.

The assumed declines in mortality are also significant, though they will have less effect on population growth. Life expectancy at birth in the world as a whole is projected to increase five-and-a-half years by 2025, with a greater gain in less developed countries (seven years) than in more developed countries (three years). The gap in life expectancies between less developed and more developed countries will diminish but stay substantial; it is now 12 years, and will be eight years by 2025. Some differences among continents will also shrink, but remain large. Life expectancy in Africa is now 53, as contrasted with life expectancy of 73 in Europe and the U.S.S.R. By 2025, life expectancy in Africa should be considerably extended to 64, but this will still be a dozen years shorter than life expectancy in Europe.

Figures 17 and 18 compare assumed trends in different projection exercises. Because judgments for individual countries differ, the current base estimates of life expectancy are slightly higher than those assumed by the U.N. The current assumed trend involves less rapid improvement than the U.N. trend, particularly at higher levels of life expectancy. This is partly due to the imposed maxima for life expectancy (82.5 for women and 75.8 for men), which are lower than those imposed by the U.N. (87.5 for women and 82.5 for men). It is also partly due to the long-run nature of these projections, which requires that gains in life expectancy be spread out over a longer period of time.

Geographic Regions and Income Groups

Population, population growth, and vital rates for subcontinental geographic regions and for groups of countries at different income levels are shown in Tables 9-12. (These and all succeeding tables appear at the end of this introduction.)

The classification by region distinguishes East, West, and North Africa; Latin America and the Caribbean from Northern America; and East and Southeast, South, and Southwest Asia (see Table 17 for the countries in each region). East and Southeast Asia, which includes China, and South Asia, which includes India, are far larger than the other regions, which each contain 100 to 400 million people. The high growth rates for Africa as a whole apply especially to East and West Africa, which are growing at 3.1 percent a year and should have six times as many people when their populations become stationary. Southwest Asia and North Africa come next, with total fertility rates above 5 and high growth rates of 2.6-2.8 percent.

The classification by income (Exhibit 1) shows that 52 of the 187 countries or economies have low per capita incomes of \$480 or less (in 1987 U.S. dollars). Most of these countries or economies are in Sub-Saharan Africa, South Asia, and Southeast Asia; they also include the majority of the ten largest countries in the world and contain 56 percent of world population. At the other extreme, high-income countries or economies, with per capita incomes of \$6,000 or more, number 38, and contain 16 percent of world population. At present, the low-income populations as a group are growing by almost 60 million a year, while the high-income populations as a group are growing by only 4 million a year. By 2025, the currently low-income countries will make up 61 percent of world population, and the currently high-income countries will make up 11 percent.

The lower-middle-income countries, with per capita incomes up to \$2,000, are as numerous as the low-income countries but have only 12 percent of world population. In this group are half of the Latin American and Caribbean countries and a variety of countries from every other region except South Asia. Population growth in these countries is actually faster at present than in low-income countries; total fertility is slightly higher (because fertility in low-income China is so low), and mortality is lower. The 35 upper-middle-income countries, on the other hand, with 9 percent of world population, have lower fertility and are mostly on the way to slower population growth. Nevertheless, even this group of countries will still grow considerably. Their stationary populations in the aggregate are expected to be more than double their present populations.

World Bank Regions

The World Bank divides borrower countries, which account for three-fourths of world population, into four regions: Africa, essentially Sub-Saharan; Asia, excluding Southwest Asia, Afghanistan, and Pakistan, but including the Pacific; Europe, the Middle East (up to Pakistan), and North Africa (EMN); and Latin America and the Caribbean (LAC). Within regions, countries are grouped into four to six country departments, most of which include more than one country (Exhibit 2). We consider the regional populations and their growth, and then the populations covered by departments, which prove to be substantially homogeneous within regions.

The division into regions puts about half the world population in the Asia region and 8 to 10 percent of the population in each of the other regions. If China and India were excluded, the remainder of the region, at 12 percent of world population, would be more comparable in size to the other regions.

The relative contributions of the regions to world population growth are shown in Figure 19 (see also Tables 13-15). The Asia region is now contributing half of world population growth, and the other three regions are each contributing 10 to 16 percent. The contribution to growth of the Asia region is projected to decline relative to the contributions of other regions: around 2030 it will actually fall below the contribution of the Africa region, and around 2060 below the contribution of the EMN region.

The contributions of both these regions are projected to rise rapidly, even with expected fertility transition in all their countries. Around 2075, the Africa region will have only a fifth of world population, but will be responsible for more population growth than all the rest of the world. The EMN region will have 15 percent of world population, but will be responsible for a quarter of the growth. Even with fertility decline taken into account, the Africa region will double in size in 23 years, the EMN region (despite including some countries of Eastern and Southern Europe) in 32 years.

Population growth in the LAC region is not insignificant either. This region is growing faster than the Asia region and has marginally higher population momentum than any other region. Even should the LAC region attain replacement fertility immediately, population would still grow 60 percent because of the young age structure.

The country departments generally have growth prospects similar to those of the regions to which they belong. The departments covering the largest populations are the single-country China and India departments and the Southeast Asia department, the latter covering 270 million people. The remaining departments each cover between 40 and 170 million people. By 2025, these other departments, assuming they will still exist in the same form, will each cover between 110 and 460 million people. Annual population growth rates for the entire 1985-2025 period will be between 2.6 and 2.8 percent in all the Africa departments; between 2.2 and 2.4 percent in three of the four EMN departments, excluding the Europe department; between 1.3 and 1.6 percent in all the LAC departments; and 1.4 percent in three of the five Asia departments, China being lower at 1.0 percent and Other South Asia (excluding India) higher at 1.9 percent.

These differences between regions and similarities within them are mainly rooted in fertility patterns (Table 16). Total fertility is between 6.4 and 6.7 in each Africa department; between 5.2 and 5.8 in three of the four EMN departments; between 3.4 and 3.9 in each LAC department; and more variable only in the Asia region, where it ranges from 2.4 to 5.2 across departments. Mortality patterns are also quite similar among departments in each region. Infant mortality per thousand is over 100 in each Africa department; between 70 and 100 in three of the four EMN departments; between 50 and 65 in each LAC department; and more variable only in the Asia region, where it ranges from 30 to 110. Projected trends will introduce only slightly more heterogeneity within regions: the Sahelian department, for instance, is expected to lag behind other Africa departments in both mortality and fertility decline.

Much more heterogeneity does exist among countries in particular regions. However, the similarities across the occasionally arbitrary groupings of countries that form departments suggest that underlying demographic regimes may be broadly shared within regions, with country variations reflecting haphazard influences that distort these regimes in different directions.

Some Country Results

Countries and economies provide a much more complex demographic mosaic than these regions, and a detailed account of their projected demographic future will not be given here. Instead, we focus on some highlights that emerge when countries are contrasted on population

Figure 19 Percentage Contribution to World Population Growth from World Bank Regions and Nonborrowers, 1985-2100

growth (Tables 17 and 18), age structure (Table 19), and vital rates.

China is the most populous country or economy, and remains so in these projections almost until the end, not quite 200 years in the future. Rankings by size among other large countries will be changing well before that point. Nigeria and Pakistan, in particular, will be moving up, from ninth-tenth today to seventh-eighth by the turn of the century and to fifth-sixth by 2025. Japan will fall out of the group of ten largest countries, and by 2025 will have fewer people than Mexico, Iran, or Viet Nam.

India presently contributes more to world population growth than China or any other country, and will continue to do so throughout the projection period. After India and China, the leading contributors to world population growth are Pakistan and Nigeria. At the other extreme, the Federal Republic of Germany is contracting by 100,000 people a year. Even recent mass migrations from the German Democratic Republic--which occurred too recently to be incorporated in these estimates--are unlikely to produce substantial population growth. Hungary is also losing population, but only a fifth as much as the Federal Republic of Germany.

Despite contributing so much to growth, none of the large countries is growing as fast as some states in the Persian Gulf and in Sub-Saharan Africa. In the Gulf, Qatar and Oman are growing by more than 4 percent a year, and Saudi Arabia, Djibouti, and Kuwait by more than 3.7 percent. In Africa, Côte d'Ivoire and Kenya are growing by more than 4 percent, and Zambia by about 3.7 percent.

Rapid growth partly accounts for Kenya having a dependency ratio as high as 120, well above any other national ratio. Other countries with ratios above 104 (other than small islands) are Botswana, the Yemen Arab Republic, and Zambia. By contrast, exceptionally low dependency ratios, indicating relatively large working-age populations, characterize such vigorous

economies as Singapore (the lowest at 42), the Federal Republic of Germany, Hong Kong, and Japan. This is projected to change: by 2025, all these low-dependency countries will have only middling dependency ratios, as their aged populations increase relative to those of working age. The highest proportions of the aged are currently in Sweden, Norway, the United Kingdom, and Denmark, where dependency ratios are at least 10 points higher than in Singapore.

The countries with most rapid growth are also among those with the highest fertility levels. Total fertility is above 7.2 in Rwanda, the Yemen Arab Republic, Kenya, Malawi, and Côte d'Ivoire, and just below this level in Saudi Arabia and Oman. At the other end are some European countries now reporting very low fertility, chief among them Italy and the Federal Republic of Germany.

The shortest life expectancies, barely 40 years, are estimated for Afghanistan and in West Africa, particularly for Guinea-Bissau, Sierra Leone, Guinea, and the Gambia. Other West African countries follow close behind. At the other end of the scale, life expectancies in Japan, France, and Iceland are almost twice as long.

Conclusion

Increasing numbers of people continue to be added to world population every year. To the 5.1 billion people in mid-1988, about 90 million were added within a year, and about 91 million more are expected to be added by mid-1990. A few developing countries have demonstrated that fairly rapid fertility decline is possible; others have exhibited gradual, long-term fertility decline. Nevertheless, the resulting lower population growth rates have not compensated for the steadily enlarging population base. The world will enter the next century with at least a billion more people than today, and will add another billion in the following decade.

Regions and individual countries do face different demographic prospects. For Sub-Saharan Africa, and even more for particular countries in the region, the likelihood of population doubling within 25 years, within the span of a generation, is sobering for anyone attempting to deal with societal problems. By the middle of the next century, the region could be more than four times its current size.

For the large countries of Asia, the numbers of people being added each year are so large as to be difficult to visualize. India adds to its population every year as many people as live in Nepal or Australia, while the annual increase in Pakistan is equivalent to one-and-a-half Singapores.

The situation for the Middle East and North Africa may appear on the surface less immediately alarming. Nevertheless, the region contains some of the fastest growing populations in the world, and eventually is likely to outstrip Asia in the number of people added each year.

Latin American and Caribbean countries are more advanced in demographic transition than Africa or South Asia. Nevertheless, 2 percent annual growth is not quite over for the region, and certainly not for particular countries. The legacy of past rapid growth, in young age structures, provides considerable momentum for further growth.

The more developed regions do not face problems of rapid growth, but they do face other demographic dilemmas. Only a few are actually experiencing population decline, but most will experience further aging of the population and rising dependency burdens.

Like all projections, these varied prospects depend on the assumptions that have been

made, which were specified above. The assumed trends in vital rates partly reflect the efforts that have been made throughout the developing world to restrain fertility, as well as to reduce mortality, in effect actually taking into account some exceptional past experiences at reducing growth. Altering these trends and producing more rapid deceleration of population growth is possible, but would probably require at least as much, and probably much more, demographic intervention as in the recent past.

Zambia	Aug 80	5662 F	Bank projection from census	Based on Bank sector report
Zimbabwe	Aug 82	7546 F	Bank projection from census	DHS 1988

Notes: When a source for an estimate is directly cited (e.g., UNPVS 7/86), the estimate is taken as is from that publication. An estimate "based on" a source is not reported in that publication but derived from data contained in it. When a source is given for a fertility or mortality estimate prior to 1985-90, the corresponding 1985-90 estimate is a projection from the earlier estimate. Citations for the main documents referred to here (usually by abbreviations) are in the list of references.

* Nature of population estimate: F = de facto, J = de jure.

-- Not applicable. No census has been taken, or no estimates were used because no projections were made for these small countries.

a Census was for entire peninsula.

b 55 people.

Note: Crude birth rates (CBR) and crude death rates (CDR) are per 1000 population; total fertility rates (TFR) are per woman 15-49 years of age; life expectancy at birth, e(0), is given in years; and infant mortality rates (IMR) are per 1000 live births. (See definitions in World Bank 1989.) World Bank regions and country departments are defined in Exhibit 2.
