

Canadian Consumers' Purchasing Behavior of Omega-3 Products

Darren Chase, John Paul Emunu, Tomas Nilsson, Diane McCann-Hiltz, and Yanning Peng

The development of innovative functional food products is a major trend in today's food industry. The growth of this industry is driven by increased consumer awareness of their own health deficiencies, increased understanding of the possible health benefits of functional foods, development in formulation technologies, a positive regulatory environment, and changing consumer demographics and lifestyles. While there has been a proliferation of omega-3 products such as milk, eggs, yogurt, and margarine in the Canadian food market, very little is known about consumers of these products.

We use ACNielsen Homescan™ data combined with survey data to develop profiles of omega-3 consumers in Canada. The focus of the study is on consumers of four products: omega-3 milk, omega-3 yogurt, omega-3 margarine, and omega-3 eggs. We investigate whether there are significant differences between consumers and non-consumers of omega-3 products based on their age, income, education, and household composition. We also investigate whether a household's use of Canada's Food Guide and the Nutrition Facts table and consideration of the health benefits of food influences the decision to purchase omega-3 products.

The results from the ordered probit model estimation show that the aging Canadian population is a major driver of omega-3 purchases. Also, the presence of children in the home increases the purchasing frequency of omega-3 yogurt and omega-3 margarine, and reading the Nutrition Facts table and considering the health benefits of food are important factors that affect omega-3 product purchases.

Public awareness of the link between diet and lifestyle-related disease has increased over the last decade (Chandler 2006; Barkema 1994; Malla, Hobbs, and Perger 2007). This increase in public awareness has led to an increased scrutiny of traditional nutritional aspects of food such as trans fat, saturated fat, cholesterol fat, fibre, salt, sodium and vitamin content, and non-traditional nutritional attributes of food such as omega-3 content. These changes in consumers' attitudes have led to a demand for more healthy foods. Subsequently, food

manufacturers have responded by producing food products that can be used to promote good health (Kinsey 1994).

Specifically, there has been a growth in the development and marketing of food products called functional foods. According to Health Canada (1998), a functional food is similar in appearance to a conventional food consumed as part of a usual diet, and is demonstrated to have physiological benefits and/or reduce the risk of chronic disease beyond basic nutritional functions. Examples of conventional functional foods include tomatoes with lycopene and wheat bran fiber, which are thought to help prevent the incidence of certain types of cancers (International Food Information Council 2006). Some functional foods can be fortified with nutrients—e.g., calcium-enriched orange juice—to help prevent specific nutritional deficiencies while others are fortified with nutrients, such as omega-3 polyunsaturated fatty acids, that could reduce the risk of chronic disease like heart disease. Omega-3 fatty acids can be found in a variety of product categories such as milk, yogurt, eggs, margarine, bread, pasta, pork, and chicken.

Awareness of omega-3 fatty acids in Canada is high, with 75 percent of Canadians stating they are

Chase, Emunu, and McCann-Hiltz are branch head, livestock statistician, and provincial consumer market analyst, respectively, Department of Agriculture and Rural Development, and Peng is market analyst, Department of Rural Economy, Government of Alberta, Edmonton. Nilsson is adjunct professor, Department of Rural Economy, University of Alberta, Edmonton.

This project was funded through the Agricultural Policy Framework, a federal-provincial-territorial initiative that aims to make Canada the leader in food safety, innovation, and environmentally responsible agriculture production. An internship for John Paul Emunu, jointly funded by the Consumer and Market Demand Agriculture Policy Research Network and Alberta Agriculture and Rural Development, supported this research. We also thank Wuyang Hu (University of Kentucky), who helped with the survey design.

aware of them (Ipsos Reid 2005a). In another poll, 10 percent of Canadians indicated they “always” choose omega-3–enhanced products when it was available and 14 percent of Canadians say they usually choose an omega-3–enhanced product (Ipsos Reid 2005b). It is not surprising that sales of select omega-3 products (milk, yogurt, margarine, and eggs) in Canada grew by 35 percent from 2004 to 2005 while sales of the respective conventional products grew by 3 percent (Chase et al. 2007). Some factors that led to the expanded development and consumption of omega-3–enhanced products include the increased understanding of the benefits of omega-3 fatty acids, growth in consumer awareness of their own health deficiencies, developments in formulation technologies, and a positive regulatory environment (Seaton 2006). Other studies suggest that consumers' preference for an omega-3 product is influenced by the level of omega-3 fatty acid in the product (McCluskey et al. 2005), the base product (e.g. fish), labelling, information attributes, and source of omega-3 fatty acid (Cox, Evans, and Lease 2008).

This study provides insight into Canadian consumers' preferences for omega-3 yogurt, omega-3 eggs, omega-3 milk, and omega-3 margarine. Specifically, the objective of this study is to assess whether household demographics, knowledge of Canada's Food Guide and nutrition labels, and consideration of health benefits influence the decision to purchase omega-3 products.

It is expected that a better understanding of the omega-3 consumer in Canada will be especially useful to decision makers in government and industry. The public incurs significant costs in the treatment of cardiovascular disease, diabetes, and high blood pressure due to poor diets and lifestyles, increasing health-insurance costs and loss of productivity. Consuming omega-3–enhanced products has the potential to positively influence health outcomes, thereby reducing health-care costs. It is because of this potential health benefit that policies should ensure the public receives accurate information about the health benefits of omega-3 products through an appropriate medium. At the same time, policies should encourage the growth and development of omega-3 products. Small- and medium-sized processors of omega-3–enhanced foods could also use the results of this research to market their products more effectively.

Data Summary

This study used ACNielsen Homescan™ data and consumer-survey data. ACNielsen maintains a panel of Canadian households, representative of the Canadian population, who regularly provide ACNielsen with their purchase information. Data from that panel were used in this research. It includes the aggregate number of trips to a store that each household made between March 2005 and March 2006 to purchase a particular omega-3 product and each household's demographic information (location, income, age and level of education of household head, and the presence of children).¹ In March 2006 a survey was administered to the same households. Of the 7,947 households that completed the survey, 34 percent also purchased an omega-3 product.² The sample data of 7,947 is fairly representative of the Canadian population with a few noted exceptions (Appendix A). For instance, households in the Maritimes, households with an older head of the household, and households with no children under the age of 18 years in the home are over-represented in the data.

The results of the survey provide some insight into the health benefits considered when purchasing food, awareness of the Nutrition Facts table on package labels, and Canada's Food Guide. The responses to three specific questions relating to the potential purchase motivators of omega-3 products are summarized below.

Health Benefits Considered when Purchasing Food

Households were queried about which health benefits they consider when purchasing food. Respondents were asked to select as many benefits as they saw fit out of 14 possible choices.³ Figure 1

¹ With regards to Homescan™ data, the analyst knows only if the household bought an omega-3 product but does not know how many conventional products or substitutes to the respective omega-3 the household bought. This limitation has implications on how the dependent variable was created when sub-dividing the number of trips into the four categories.

² Researchers at Alberta Agriculture and Rural Development designed the survey.

³ This is the reason why the percentages in Figure 1 do not add up to 100.

Figure 1. Health Benefits Considered When Purchasing Food.

shows that most households buy a certain type of food if they believe it will improve their health in general, control/reduce cholesterol, aid in weight loss/control, or reduce the risk of heart disease or cancer.

Awareness of the Nutrition Facts Table

Households were queried about their awareness of the Nutrition Facts table on packaged food products and the information they look for on the table when buying a product for the first time. Of the 89 percent of households that stated they are aware of the Nutrition Facts table, 63 percent actually read it. Only 11 percent of the households were not aware of the Nutrition Facts table.

Awareness of Canada's Food Guide

Another question queried households about whether they had heard of Canada's Food Guide. Just over half of the households, 51 percent, have seen or heard of Canada's Food Guide and use the information while 40 percent of households have seen or

heard of it but do not use the information. Only nine percent of the households have not seen or heard of Canada's Food Guide.

Methodology and Results

Theoretical and Empirical Models

The model used in this study follows the random utility maximization (RUM) framework rooted in the economic theory of consumer choice (McFadden 1974). In these models it is often assumed that a household is capable of making "rational" decisions that optimize their internal utility.

For each omega-3 product, we assume that a household faces a choice between never purchasing (Nv), purchasing once (On), purchasing occasionally (Oc), and purchasing frequently (Fr). Utilities derived from the purchasing decision are given by U_{nv} , U_{on} , U_{oc} , and U_{fr} , respectively, and these utilities are not observable. The observable variables are the purchase decisions k (where $k = Nv, On, Oc, Fr$) and a vector of consumer characteristics (X). The utility of a household i is postulated as

$$(1) U_{ki} = V_{ki} + \varepsilon_{ki} = \beta x + \varepsilon, \varepsilon \sim N(0,1),$$

where U_{ki} is the latent, unobserved utility for choice alternative k , V_{ki} is the explainable part of the latent utility that depends on the purchasing decision and a set of the household's demographic characteristics and attitudes, and ε_{ki} is the random component of the latent utility associated with the choice k and household i .

Household i 's choice ordering between never purchasing (Nv), purchasing once (On), purchasing occasionally (Oc) and purchasing frequently (Fr) the respective omega-3 products is modeled in the following way. Household i ranks the decision to purchase a respective omega-3 product in one of the four categories. For example, Z_i can be interpreted as additional utility derived by household i choosing to purchase an omega-3 product once (On) over never purchasing (Nv), so that

$$(2) Z_i = (V_{Oni} + \varepsilon_{Oni}) - (V_{Nvi} + \varepsilon_{Nvi}) \\ = (\varepsilon_{Oni} - \varepsilon_{Nvi}) - (V_{Oni} + V_{Nvi}).$$

A household expresses strong disapproval for a specific purchase occasion if Z_i is below some threshold value (e.g., μ_1), shows moderate disapproval if Z_i is above μ_1 but below another threshold value μ_2 , and shows approval of a purchase decision if Z_i is above μ_2 . Formally, household i 's choice ordering is denoted by U_i where $U = 0$ implies never purchasing, $U = 1$ implies purchasing once, $U = 2$ implies purchasing occasionally, and $U = 3$ implies purchasing frequently and can be expressed as

$$(3) \begin{aligned} U = 0 & \quad (\text{Never}) \text{ if } \mu_i^* \leq \mu_1, \\ U = 1 & \quad (\text{Once}) \text{ if } \mu_1 \leq \mu_i^* \leq \mu_2, \\ U = 2 & \quad (\text{Occasionally}) \text{ if } \mu_2 \leq \mu_i^* \leq \mu_3, \\ U = 3 & \quad (\text{Frequently}) \text{ if } \mu_3 > \mu_i^*, \end{aligned}$$

where the unknown μ_i^* 's are estimated along with the β 's. Assuming that the ε 's are normally distributed, the ordered probit maximum likelihood estimator results and the probabilities are:

$$(4) \begin{aligned} \Pr(U = 0|x) &= F(-x'\beta), \\ \Pr(U = 1|x) &= F(\mu_1 - x'\beta), \\ \Pr(U = 2|x) &= F(\mu_2 - x'\beta) - F(\mu_1 - x'\beta), \\ \Pr(U = 3|x) &= F(\mu_3 - x'\beta), \end{aligned}$$

where F is the cumulative function of a standard

normal distribution. In the above model the μ 's are unknown parameters that separate the adjacent categories. The estimated β coefficients of Equation 1 do not directly represent the marginal effects of the independent variables on the probabilities of choice. The marginal effects of changes in the explanatory variables are calculated as

$$(5) \begin{aligned} \partial \Pr(U = 0|x) / \partial x &= F(-x'\beta)\beta, \\ \partial \Pr(U = 1|x) / \partial x &= [F(\mu_1 - x'\beta)]\beta, \\ \partial \Pr(U = 2|x) / \partial x &= [F(\mu_2 - x'\beta) - F(\mu_1 - x'\beta)]\beta, \\ \partial \Pr(U = 3|x) / \partial x &= F(\mu_3 - x'\beta)\beta, \end{aligned}$$

where F is the probability density function of the standard normal variable. For continuous independent variables, marginal effects are calculated at the sample means; however, for binary or dummy variables, they are calculated as the difference between the probabilities at the two end points, $\Pr(y|x = 1) - \Pr(y|x = 0)$. The marginal effects for a given variable sum to zero across the different response categories.

Empirical Application

It is assumed that the decision to purchase a respective omega-3 product (eggs, milk, yogurt, and margarine) depends on how often a household goes to the grocery store or retail store and purchases the respective product (number of trips). The more trips a household makes to the grocery store to purchase an omega-3 product, the higher the expenditure on that omega-3 product, and consequently, the higher the preference or utility for that omega-3 product. It is also worth noting that for each trip taken a household did purchase an omega-3 product. We also found the number of trips was positively correlated with total expenditure. Thus by using trips as a proxy for total expenditure we were able to capture a household's preferences for the respective omega-3 products. For each of the products the number of trips was divided into 0 = never (Nv), 1 = once (On), 2 = occasionally (Oc), and 3 = frequently (Fr).

Determining the "never" and "once" categories was straightforward. Since each household in the panel had the opportunity to scan their omega-3 purchases and also do the survey, we assume that consumers who never scanned their omega-3 purchases but participated in the survey chose not to

buy an omega-3 product. Thus “never” represents those households that never took a trip to the grocery store to purchase an omega-3 product while “once” represents those households that took a single trip to the grocery store. The “occasionally” and “frequently” categories were developed based on the frequencies of the number of trips to the grocery store to ensure that each category had sufficient data to carry out the analysis (Table 1).

It should be noted that these frequencies pertain to omega-3 products only, since we do not know how many trips the household took to purchase the conventional products or substitute products. Consequently, we label a household that buys omega-3 eggs five or more times a year a “frequent” purchaser of omega-3 eggs, rather than a frequent purchaser of eggs in general. The same explanation can be applied to the other omega-3 categories.

Table 1 shows the number of households that purchased omega-3 products ranged from approximately five percent for omega-3 milk to 20 percent for omega-3 eggs.

The following empirical model is used to estimate the relationship between the probability that a household will purchase an omega-3 product based

on number of trips and their personal characteristics and attitudes:

$$(6) \quad U_i = \beta_0 + \beta_1 MART + \beta_2 MBSK + \beta_3 PQ + \beta_4 ON + \beta_5 BC + \beta_6 Income + \beta_7 Age1 + \beta_8 Age2 + \beta_9 Age3 + \beta_{10} Age4 + \beta_{11} Child + \beta_{12} Education + \beta_{13} Table + \beta_{14} FoodGuide + \beta_{15} HealthBenefits + \varepsilon_i,$$

where U_i is the purchase of omega-3 products based on the number of trips and is ranked between 0 and 3.

Table 2 provides a summary of the variables used in estimating the model. Location of residence is a dummy variable equal to one if the purchase of the omega-3 product was in a particular region and zero otherwise. A dummy variable is created for each region with the exception of Alberta, which is the base case. Income is a continuous variable representing the total household income before taxes. Age is a dummy variable reflecting the age of the head of the household. A dummy variable is created for each age group with the exception of over 65 years, which is the base case. Child is a dummy variable indicating the presence of children in the

Health Benefits	Health Benefits	3.52	2.88
Range from 0 to 13, with 0 being no health benefit and 13 being all of the health benefits listed below: General-improved health, improve memory, improve mental health, improve visual function, increase resistance to disease, improve energy levels, reduce heart disease, reduce cancer risk, reduce osteoporosis risk, control/reduce risk of diabetes, control/reduce cholesterol, weight loss/control, other			

household. Education is a continuous variable representing the education level of the respondent. Table and Food Guide are dummy variables that indicate whether consumers read the Nutrition Facts table and use Canada's Food Guide, respectively. Health benefit is a continuous variable that refers to the health benefits that households consider important when deciding which foods to buy.

Model Estimation

Four ordered probit models for the different omega-3 products (eggs, milk, yogurt, and margarine) were estimated to explain the household's preferences for omega-3 products. The marginal effects (M.E.) of the explanatory variables along with their t-ratios are reported in Appendices B–E. Also reported in these tables are the standard errors (S.E.), McFadden's R^2 , and estimated threshold parameters for the index functions μ_1 and μ_2 . McFadden's R^2 , a nonlinear transformation of the restricted and unrestricted maximum-likelihood values, is a good measure of fit. The estimated threshold parameters are significant, indicating the ordered probit model with four purchasing options is highly appropriate.

The estimated coefficients and standard errors reveal which factors influence households' purchase intentions for omega-3 eggs, milk, margarine, and yogurt. However, the coefficients from the ordered probit model are difficult to interpret; therefore, caution must be used when making inferences (Greene 2003). The marginal effects provide better insights into how the explanatory variables affect each household's decisions to purchase omega-3 products. The marginal effects represent changes in the dependent variable for a one-percent change in the independent variable (explanatory variable) in question, holding all other independent variables constant at their sample means. Therefore only the marginal effects are reported in Appendices B–E.

Empirical Results

The following discussion is based on the summary of marginal effects presented in Table 3. Our interpretation is limited to the households that "never" purchase an omega-3 product and those respondents that "frequently" purchase an omega-3 product.⁴ In

⁴ Information on the Once and Occasionally options are also shown in Appendices B–E.

Table 3, a statistically significant positive marginal effect is represented by "+" and a statistically significant negative marginal effect is represented by "-". If the marginal effect is not statistically significant, the box is left blank.

The results suggest that demographic variables have a different impact on purchases of each of the omega-3-enhanced products. Region seems to be more influential in the purchase of omega-3 eggs than for the other omega-3 products. For instance, consumers from the Maritimes, Quebec, Ontario, and British Columbia appear to purchase omega-3 eggs more frequently than do consumers in Alberta (the base case), while consumers in Manitoba and Saskatchewan are more likely to never purchase omega-3 eggs than are consumers in Alberta.

Consumers with higher educations and higher incomes are more likely to be frequent purchasers of omega-3 eggs and omega-3 yogurt, while income and education do not appear to have any impact on the purchase of omega-3 margarine and omega-3 milk.

The results suggest that consumers over 65 years old (the base case) are more likely to purchase an omega-3 product, with the exception of yogurt, than are any other age category. As people age, they are likely to have more health concerns and could be consuming some omega-3 products to address some of these health concerns. Households with children appear to be more likely than households without children to never purchase omega-3-enhanced eggs and omega-3-enhanced milk. However, households with children are more likely than households without children to frequently purchase omega-3-enhanced yogurt. Given that yogurt is a convenient and nutritious food that most children like, it is not surprising that households with children are more frequent consumers of omega-3-enhanced yogurt. In terms of marketing, producers and processors of omega-3 yogurt should continue to target households with children since parents typically want to provide the best nutrition possible for their children and many health benefits of specific omega-3 fatty acids (supporting the normal development of the brain, eyes, and nerves) are particularly important for children.

Consumers who use Canada's Food Guide are more likely to frequently purchase omega-3-enhanced yogurt. Our survey found that 51 percent of Canadians had heard of and used Canada's Food

Guide. This indicates that a product like Canada's Food Guide could offer an effective channel that the government can use to inform people of the benefits of consuming omega-3 products.

Consumers who read the Nutrition Facts table frequently purchased omega-3 products. This supports the notion that people who are concerned about their health tend to read food product labels. In Canada, federal government legislation requires disclosure of the nutritional contents for most pre-packaged food products on a standardized label. How consumers interpret and use the information contained on the Nutrition Facts table is important to policy makers. The fact that in our survey 63 percent of consumers stated they read the Nutritional Facts table presents a great opportunity for processors of omega-3 products to place health claims about omega-3 products on or near the table.⁵

⁵ Putting health claims on products must be done in accordance with federal regulation.

Households who purchase food at the grocery store to attain health benefits are more likely to purchase omega-3 eggs, margarine, and yogurt. This bodes well for marketers of omega-3 products since the results of our survey suggest that some of the most frequently stated health benefits consumers consider when purchasing a food, such as reducing the risk of heart disease, are consistent with health benefits provided by consuming omega-3 fatty acids.⁶

Conclusion

The increased awareness of the link between diet and lifestyle-related diseases has resulted in consumers seeking increased health benefits from their food choices. Approving health claims is one way

⁶ A summary of health benefits provided by consuming omega-3 fatty acids can be found at <http://www.ific.org/publications/factsheets/omega3fs.cfm>.

that governments have recognized the interconnectedness between food and health. Industry has addressed specific health concerns through product development such as creating omega-3-enhanced products.

The percentage growth in omega-3 product sales (eggs, milk, yogurt, and margarine) exceeded the percentage growth in conventional food-product sales. This growth in the omega-3 food category presents opportunities for firms looking to expand their market presence. Thus there is a need to better understand what is influencing consumer's decisions to purchase or not purchase omega-3 products. Knowledge of how these choices vary by household is relevant to decision makers in government and industry who are concerned about food-labeling policy, market segmentation, promotion and education.

The results from the ordered probit model show that consumers who are over 65 years old are more likely to purchase omega-3 products. North America's population is aging; therefore it would be a good marketing strategy to target this particular age group. To put this in perspective, in 2001 one Canadian in eight was 65 or over. By 2026, one Canadian in five will have reached age 65 (Health Canada 2002).

We also found that the presence of children in the home increases the purchasing frequency of omega-3 yogurt and omega-3 margarine. Knowledge and use of the Nutrition Facts table and the health benefits associated with a food are important purchase motivators for omega-3 products.

The results of this research suggest that more consumer research on omega-3 fatty acids should be done. Future research could assess consumers' awareness and understanding of the different types of omega-3 fatty acids and the associated health benefits. Other research could also assess how the various omega-3 health claims influence their purchase decision and their willingness to substitute between conventional and products with additional health benefits. This type of research would be beneficial to food manufacturers and policy developers alike.

 Statistics Canada. 2006. "CANSIM Database: Information on Household size 2001." Table No.750019.

Appendix A. Comparing Sample Data with 2001 Census Profile of Canada.

	Panel Track™ Data (7947 households)	2001 Census Profile Canada
Region	Percent	Percent
Maritimes	12.2	5.9
Quebec	25.5	24.2
Ontario	30.7	39.0
Manitoba/Saskatchewan	11.0	8.0
Alberta	10.3	9.9
BC	10.3	13.0
Household size		
Single member	26.6	25.7
Two members	41.3	32.6
Three members	12.6	16.3
Four members	12.9	22.3 (4–5 persons)
Five or more members	6.6	3.1 (6 or more persons)
Household income		
Under \$20,000	11.3	19.0
\$20,000–\$29,999	13.3	11.9
\$30,000–\$39,999	13.8	11.5
\$40,000–\$49,999	11.7	10.6
\$50,000–\$69,999	19.3	17.5
\$70,000+	30.6	29.5
Age ^a		
<35	6.0	22.6
35–44	20.6	17.0
45–54	24.8	14.8
55–64	22.9	9.5
≥65	25.7	13.0
Children		
Children under 18	23.1	48.0
No children under 18	76.9	52.0
Language		
Non-French	76.3	75.9
French	23.7	24.1
Education		
Not completed high school	14.7	25.9
Completed high school	17.4	11.9
Some technical or college	13.4	8.4
Completed technical or college	22.2	26.0
Some university	9.8	11.2
Completed university	22.4	18.6

^a For the census data, the age group under 18 was not considered when computing the under-35 age group. This is why this category might not add to 100.
