ABSTRACT

Rise in the underground economy creates problems for the policy-makers to formulate economic policies, especially the monetary and fiscal policies. It is found that if there was no tax evasion, budgets balance might have been zero and positive for some years and we would not have needed to borrow as much as we had borrowed. It is concluded that the impact of the underground economy is significant to the movements of the formal economy, but the impact of formal economy is insignificant in explaining the movements in the underground economy. In the long run, underground economy and official economy are positively associated. It is estimated that the underground economy ranges between Rs 2.91 trillion and Rs 3.34 trillion (54.6 percent of GDP to 62.8 percent of GDP respectively) in 2005 and tax evasion ranges between Rs 302 billion and Rs 347 billion (5.7 percent of GDP to 6.5 percent of GDP respectively) in 2005. Underground economy and tax evasion were increasing very rapidly in the early 1980s but the rate of increase accelerated in the 1990s. It declined in 1999, but reverted to an increasing trend until 2003. It declined again in 2004 and 2005.

JEL classification: E26, H26

Keywords: Underground Economy, Tax Evasion

1. INTRODUCTION

Illegal activities such as smuggling, corruption, black-marketing, narcotics, informal legal jobs etc. constitute the underground economy. These activities are not in the tax net and have significant negative impact on social welfare of the country. Almost all the transactions made in the underground economy are through cash, e.g., payments to the contractual workers, transactions in illegal sales, transactions involved in smuggling and drug trafficking, cash payments to the shopkeepers who do not provide valid cash memos¹ etc. In general, self-employed persons are involved in tax evasion and underground economic activities because there is no formal system of documentation of self-employed persons and their activities.

Underground economy generally exists in every country, however, the policy-makers are especially concerned about the rise of the underground economy. It creates difficulties for the policy-makers to formulate the policy especially the monetary policy. On the other hand, increase in tax evasion is mostly associated with the fiscal policy, i.e., increase in tax rates erodes the tax base, which eventually reduces the willingness to pay taxes even when the Government reduces the tax rates. Government thus fails to impose progressive taxation and in order to get revenues they impose different taxes or increase the tax rates or increase the price of those commodities whose demand is inelastic to its price, e.g., wheat flour (this is known as inflation tax). As a result, fiscal deficit and inflation increases in the country. This problem results in gradual weakening of the economic and social basis of collective arrangements [Schneider and Enste (2000)]. Furthermore, the statistics on unemployment, labour force, income, consumption and other welfare indicators are unreliable, which is the major hurdle in the path of policy-making.

Contrary to the above, increase in the underground economy affects positively to the formal economy. Empirical findings of Schneider (1998) show that at least two-third of the income earned in the shadow economy is immediately spent in the official economy. However, some studies show opposite results, e.g., Yasmin and Rauf (2003) conclude that the underground economy and tax evasion affects formal GDP² negatively in Pakistan.

Acknowledgements: I am thankful to Dr Nadeem Ul Haque, Dr A. R. Kemal, Dr Faiz Bilquees, and Mr Mahmood Khalid for sending me useful comments on this paper. All errors of course should be attributed to the author.

¹Although they accept credit cards, the shops even in Islamabad prefer taking cash because use of credit cards forces them to pay taxes.

²There are certain econometric problems with their regression approach.

Tax system should be simple and easy to understand because loopholes in the complex tax system tempt people to evade taxes which they might pay otherwise. Until the agriculture tax was not imposed industrialists and traders showed their income as income from agriculture and were exempted from taxation. Even now the tax on agriculture sector is significantly lower and this practice of tax evasion still continues. In the public sector government employees are not allowed to work anywhere besides their main office. However, there are many persons who work at more than one place³ and do not report their income from the second job, which remains out of the tax net.

It is difficult to estimate the exact amount of tax evasion and the size of the underground economy. A number of researchers [Shabsigh (1995); Ahmad and Ahmad (1995); Iqbal, Qureshi, and Mahmood (1998); Aslam (1998); Khalid (2002); Kemal (2003) and Yasmin and Rauf (2003)] have tried to estimate it using Tanzi's (1980, 1983) monetary approach. However, this is an indirect approach to estimate the underground economy, which can show the trend in underground economy but fails to provide the exact numbers [for more details see Kemal (2003)].

The primary objective of this paper is the fresh assessment of the underground economy and tax evasion. We also checked the long run relationship between the underground economy and formal economy and the short run causality between the two variables. The paper also explores the consequences of the underground economy and tax evasion.

The plan of the paper is as follows: Section 2 describes the possible causes of the underground economy; Section 3 gives overview of the past studies; Section 4 describes the data and methodology; Empirical results are presented in Section 5; Consequences of the underground economy and tax evasion are described in Section 6; Section 7 explores the linkages between the formal and the underground economy; and Concluding points are drawn in Section 8.

2. MAIN CAUSES OF INCREASE IN THE UNDERGROUND ECONOMY

The growth of the underground economy is associated with various factors, such as rise in taxes and social security burdens, intensity of regulations in the official economy, especially the labour markets including forced reduction of weekly working time, early retirement, prohibition of not working at more than one office etc. Apart from economic factors certain non-economic factors also lead to the expansion of the underground economy such as unwillingness to show the accurate income etc. According to Schneider and Enste (2000) micro-

³At high rates of inflation, while income levels remain the same, people need to earn more to maintain the same living standard if not better.

sociological and psychological approaches can provide interesting additional insights in the decision-making process of individuals choosing to work underground. For example, the decline of civic virtue and loyalty towards public institutions and decline in tax morale of the people.⁴

2.1. The Burden of Tax and Social Security Contributions

The most important determinant of the increase of the underground economy is the rise in tax and social security burdens [see Tanzi (1982, 1999); Frey and Pommerehne (1984); Feige (1989); Pozo (1996) and Johnson, Kaufmann, and Zoido-Lobaton (1998)]. As a result of increase in tax rates people generally get involved in those activities where they can earn more and pay as less taxes as possible. Schneider and Enste (2000) state that bigger the difference between the total cost of labour in the official economy and after tax earnings (from work), greater the incentive to avoid this difference and work in the underground economy. Since this difference depends broadly on the social security system and the overall tax burden, therefore, these are the key features of the existence and rise of the underground economy (Ibid).

Loayza (1996) estimates the size of the informal sector in fourteen Latin American countries and finds that tax burden and labour market restrictions increases the underground economy activity, while the strength and efficiency of government institutions reduces the underground economy. Neck, Hofreither, and Schneider (1989) investigated the determinants of a household's supply of underground labour and its demand for underground goods. They concluded that higher marginal income tax rates imply a higher supply of underground labour, and higher wage rates in the official economy imply a lower supply of underground labour. On the other hand, they showed that the firms' demand for underground labour and supply of underground goods depend positively on the indirect tax and wage rates in the official economy, i.e., higher the tax rates higher would be the underground economy.

Schneider and Neck (1993) emphasise the complexity of taxation system. A complex tax schedule allows more legal tax avoidance by providing various tax exemptions and reductions. However, exemptions and reductions in taxes always lead to better welfare of the people at least in the short run.

The main problem with the underground economy activity and tax evasion is that once an individual gets involved it becomes almost impossible to come out of it for various reasons, such as (i) their informal income, if not declared, cannot be taxed since there is no proper documentation for the informal sector in Pakistan. On the other hand, everything is taxed in the formal sector, (ii) Even when the policy of taxation is relieved (either reduction in tax rates or amnesty schemes) tax evaders have fear that government is trying to

⁴For further details see Frank (1988).

cheat them; once they are registered with the tax network the tax rates will be raised once again and they will be picked up very easily because then the government will have full information about their informal activities and incomes. Spiro (1993) finds for Canada that people once working in the underground economy prefer the high profiles from irregular activities, develop social networks and personal relationships and hence will not return to the official economy even in the long run.

2.2. Intensity of Regulations

Regulatory frameworks are generally designed to get control over certain things. For example, the role of monopoly control authority (MCA) is to protect consumer rights by creating competition among different firms so that consumers can buy same products at competitive prices from different producers. It prohibits the monopoly situation in the country, which improves efficiency as well. Increasing the number of regulations for any market is not a good policy to adopt; more regulations mean more restrictions which lead to increased labour costs in the official economy. Since most of these costs can be shifted onto employees, it reduces individuals' choices to work in the official economy. As a result, they would work in the informal/unofficial sector, which thus leads to more tax evasion and increase in the underground economy. Intensity of regulation is often measured by the number of laws and requirements such as licenses, and various other labour laws, e.g., labour restrictions for foreigners, price controls and trade barriers.

Johnson, Kaufmann, and Shleifer (1997) predict, *inter alia*, that countries with more regulations tend to have a higher share of unofficial economy in total GDP. They estimated that one point increase of the regulation index (ranging from 1 to 5, with 5 = the most regulation in a country) leads to 8.1 percentage point increase in the share of the underground economy. They conclude that the enforcement of regulation is the key factor for the burden levied on firms and individuals that drives them into the underground economy. Friedman, *et al.* (1999) show that more regulations are correlated with larger underground economy. They estimated that one point increase in an index of regulation (ranging from 1–5) leads to 10 percent increase in the underground economy.^{5, 6}

Johnson, Kaufmann, and Zoido-Lobaton (1998) find that countries with a better rule of law have smaller underground economy. Transition countries have higher levels of regulation leading to a significantly higher incidence of bribery, higher effective taxes on official activities, and a large discretionary framework of regulations and consequently, larger underground economies.

⁵Both studies are based on cross country analysis.

⁶To read more about cost of regulation see De Soto (1989).

These findings demonstrate that government should put more emphasis on reducing the intensity of regulations or at least improve the enforcement of laws and regulations instead of increasing the number of regulations [Schneider and Enste (2000)].

2.3. Social Transfers

Social transfers such as zakat and subsidies⁷ discourage people to work especially in the official economy because their overall income is higher if they receive these transfers while working in the underground economy. However, this does not contribute significantly to the underground economy as far as Pakistan's is concerned. Pensions which have a major proportion in social transfers in Pakistan may contribute but very little to the underground economy.

3. OVERVIEW OF LITERATURE: EVIDENCE FROM THE PAST

Kemal (2003) comprehensively reviews the past studies including Shabsigh (1995), Ahmad and Ahmad (1995), Iqbal, Qureshi, and Mahmood (1998), and Aslam (1998). All these studies used Tanzi's (1980, 1983) monetary approach to estimate the size of the underground economy and tax evasion. There are several shortcomings of this approach, which lead to incomparable estimates of the underground economy and tax evasion (in figures).⁸ These problems were also comprehensively discussed in my previous paper, i.e., Kemal (2003). Let's look at the other studies which were not discussed in my previous paper.

Khalid (2002) and Yasmin and Rauf (Y-R) (2003) estimated the underground economy and tax evasion using monetary approach but got different estimates from Kemal (2003). However, the trend of the underground as percentage of GDP is the same in all the three studies (see Graph 1 below), which shows that the underground economy as percentage of GDP started increasing at a rapid rate after 1991 and in 1998 it was maximum and then started declining.

Time period and benchmark period is the same in Y-R (2003) compared to Kemal (2003) but the definition of dependent variable⁹ is different. Moreover, interest rate is used by Y-R (2003) as an explanatory variable which was absent

⁷In Pakistan there is not social security system which says that if you are unemployed and permanent resident of that country you will get minimum amount to maintain your subsistence level. This system is applied in UK and some other countries.

⁸All the indirect approaches have several shortcomings and monetary approach is the best among those approaches [see Kemal (2003)].

⁹Y-R (2003) used ratio of currency in circulation to M2 as dependant variable, while Kemal (2003) used ratio of foreign currency accounts in conjunction with currency in circulation to M2 as dependant variable.

in Kemal (2003) due to insignificant impact on the dependent variable. Dummy variable is not used by Y-R (2003), which was used by Kemal (2003) to capture the impact of hundi after liberalisation of foreign currency accounts. Similar to Iqbal, Qureshi, and Mahmood (1998), Y-R (2003) used lagged value of tax to GDP ratio as an explanatory variable, while Kemal (2003) used the current period tax to GDP ratio. The results of the estimated equation of both the studies are given in Table 1.

Khalid (2002) and Kemal (2003) used same methodology, same dependant variable but different benchmark periods, i.e. former used 1975 as benchmark year while later used 1973 as benchmark year. Moreover, real interest rate and GDP per capita is used by Khalid (2002) which are insignificant in Kemal (2003) and were not used in the final equation. Instead of using per capita growth Kemal (2003) used GDP growth as a proxy to economic development.

The estimates of underground differs due to different dependent variables used by different authors, different benchmark periods taken in each study, different explanatory variables chosen, different time period etc. The estimates of the underground economy calculated from this approach are good in examining the trend but not the exact size of the underground economy.

4. DATA AND METHODOLOGY

Annual data on currency in circulation, M1, M2, total number of bank deposits, total number of bank accounts, interest rate, and resident foreign currency accounts are taken from various issues of the Annual Report of The State Bank of Pakistan and Hand Book of Statistics on Pakistan Economy 2005 by the State Bank of Pakistan. Data on GDP, GNP, inflation, and real per capita income are taken from various issues of the Economic Survey, and the data on, sales tax on imports, custom duties, and total tax revenues are taken from various issues of the CBR Annual Report. Data are collected from 1973 to 2005 because disaggregated data of money supply, GDP, and GNP are not available for Pakistan for the pre 1973 period.

4.1. Construction of Variables

Real interest rate is computed by subtracting inflation rate from nominal interest rate. Variable of banking services (BS) is obtained by dividing total number of bank deposits by total number of bank accounts. Growth rate of GDP is calculated by the following formula applied on GDP at constant factor cost.

$$\text{Growth rate of GDP} = \frac{GDP_t - GDP_{t-1}}{GDP_{t-1}}$$

4.2. Model

The size of the underground economy can be estimated by direct as well as indirect methods. Direct methods are micro approaches that rely upon either survey and samples based on voluntary replies, or tax auditing [for details see Kemal (2003); Schneider and Enste (2000) and Pyle (1989)]. Indirect methods rely on discovering the traces which the black economy leaves in its wake. There are different types of indirect approaches such as monetary approach, income and expenditure approach, labour market approach and physical input method (electricity consumption approach). The details of these approaches described in Kemal (2003), Schneider and Enste (2000) and Pyle (1989) show that every approach has its shortcomings but monetary approach is the best and most commonly and easily applied approach among these to estimate the size of the underground economy and tax evasion.

Kemal (2003) concluded from replicating different studies using Tanzi's monetary approach that choosing a functional form is a major concern because using equation in double log form, semi log form or simple linear form fundamentally changes the results; choosing a meaningful benchmark is also a major obstacle, which should be resolved at the outset; changing the time period changes the results drastically, also evident from Tanzi (1983); inclusion and exclusion of variables from the model results in significant difference in the

estimates, therefore, inclusion of relevant variables is very important. Definition of dependent variable is also vital and should be defined with great care.

According to Tanzi (1980), the estimates of the underground economy computed from indirect approach (monetary approach) should not be taken as precise measures, it could be taken as broad indications of trends and of orders of magnitude because they are sensitive to the assumptions. Therefore, whatever results are obtained from the estimation should not be taken as the exact size of the underground economy and tax evasion. Similar to Kemal (2003) in this paper we have formulated the Tanzi specification according to the macro economic situation in Pakistan and to check the robustness of the estimates we estimated three models, described below.

$$\left(\frac{CC+FCA}{M2}\right)_t = \alpha + \beta\left(\frac{T}{Y}\right)_t + \gamma BS_t + \phi G_t + \lambda D + \delta\left(\frac{CC+FCA}{M2}\right)_{t-1} + \varepsilon_t \quad \dots \quad \dots \quad \dots \quad (1)$$

$$\left(\frac{CC+FCA}{M2}\right)_t = \alpha + \beta\left(\frac{T}{Y}\right)_t + \gamma BS_t + \phi G_t + \lambda D + \phi inf_t + \varepsilon_t \quad \dots \quad (2)$$

$$\left(\frac{CC+FCA}{M2}\right)_t = \alpha + \beta\left(\frac{T}{Y}\right)_t + \phi inf_t + \lambda D + \delta\left(\frac{CC+FCA}{M2}\right)_{t-1} + \varepsilon_t \quad (3)$$

CC = Currency in Circulation

DD = Demand Deposits

FCA = Foreign Currency Accounts

M2 = Money Supply

T = Total Tax Revenues

Y = GDP at current market prices

BS = Banking Services

G = Growth Rate of Real GDP

Inf = Rate of Inflation

D = Dummy variable defines 1 for 1990 to 2005 and zero otherwise

ε = Error Term

Subscript *t* shows time period.

Year 1973 has been chosen a benchmark because reliable statistics for Pakistan in the pre-1973 period are not available and the severity of the problem of the underground economy also started after nationalisation. Significance of using foreign currency accounts in conjunction with the currency in circulation as the dependent variable arises from the fact that foreign currency accounts served as a powerful source of financing the transactions in the underground

economy because the accounts are completely confidential, easily transferable and can be used as liquid money. Significance of using demand deposits in conjunction with currency in circulation and foreign currency accounts as dependent variable is that demand deposits can be treated as liquid money because we can draw as much money as we want from these accounts.¹⁰ Dummy variable is used to capture the impact of foreign currency accounts after 1990.

4.3. Methodology

For each year predicted values of currency ratio including tax variables $\left(\frac{CC + FCA}{M2}\right)_t$ and without tax variables $\left(\frac{CC + FCA}{M2}\right)_{wt}$ are calculated by estimated regression equation. The difference between the two terms gives us an indication that how much currency holding is tax induced. This difference is then multiplied with M2 to get illegal money. Subtracting illegal money from M1 gives legal money in the economy. Velocity of money in the underground economy is calculated by dividing national income with legal money. Assuming velocity of the money is the same for both legal and illegal money, multiplying velocity of money with illegal money gives the underground economy. Tax evasion is calculated by multiplying underground economy with total tax to GDP ratio. Mathematically we can write it as,

$$Illegal\ Money\ (IM) = \left(\left(\frac{CC + FCA}{M2} \right)_t - \left(\frac{CC + FCA}{M2} \right)_{wt} \right) * M2 \quad \dots \quad (4)$$

$$Legal\ Money\ (LM) = M1 - IM \quad \dots \quad \dots \quad \dots \quad \dots \quad (5)$$

$$Velocity\ (V) = \frac{GNP}{LM} \quad \dots \quad \dots \quad \dots \quad \dots \quad (6)$$

$$Underground\ Economy\ (UE) = IM * V \quad \dots \quad \dots \quad \dots \quad (7)$$

$$Tax\ Evasion\ (TE) = UE * \left(\frac{Total\ Taxes}{GNP} \right) \quad \dots \quad \dots \quad \dots \quad (8)$$

5. EMPIRICAL FINDINGS AND RESULTS

Dependent variable is the same in all the three models as was in Kemal (2003) and the results are reported in Table 2. The results turned out to be different from my previous estimated equation in (Ibid). The significance level of the lagged dependent variable increases from 7 percent to 25 percent level of significance.

¹⁰If the amount is too big, one can draw from his/her account on only one-day notice.

Table 2

Results of Estimates of Regression Equation

Variables	Equation 1		Equation 2		Equation 3	
	Coefficient	<i>t</i> -values	Coefficient	<i>t</i> -values	Coefficient	<i>t</i> -values
Constant	0.116	1.92***	0.118	1.81***	0.015	0.21
Tax to GDP ratio	0.889	1.90***	1.745	3.53*	1.159	2.42**
Banking Services	-1.14E-06	-3.12*	-1.43E-06	-4.33*		
Growth Rate of GDP	-0.348	-1.25	-0.597	-2.20**		
DUM 91	0.061	3.05*	0.091	6.10*	4.12E-02	-2.77*
Lag Dependent Variable	0.358	2.19**			0.42	2.64**
Inflation Rate			0.152	1.75***	0.194	2.38**
	R ² = 0.75		R ² = 0.73		R ² = 0.75	
	F = 15.84		F = 14.66		F = 19.22	
	h-test = -0.10		DW = 1.77		h-test = -0.93	

Note: *, **, ***Indicate significant at 1, 5 and 10 percent level of significance respectively.

Equation 1

It can be seen from Table 2 that the coefficient of the tax to GDP ratio is positive and significant at 6 percent level. This implies that higher the tax rate, higher will be the currency holdings. Negative and significant association between the banking services and currency ratio implies that the improvement in banking services significantly lowers the demand for currency holding. Coefficient of growth shows that higher level of economic growth is expected to decrease the demand for currency holdings but its impact is insignificant. Since its t -value is greater than one and the signs of the coefficient is also correct, therefore, we can use it for predicting (estimating) the size of the underground economy. Dummy variable, which shows that impact of *hundi* and other transactions through foreign currency accounts, turns out to be a highly significant variable. Coefficient of the lagged dependent variable is positive and significant. R^2 is 0.75 and the F -statistic is also significant which implies that the explanatory variables are significantly explaining the dependent variable. h -test shows that there is no serious problem of autocorrelation in the regression estimates.

Equation 2

In Equation 2 the insignificant lagged dependant variable is replaced with the inflation rate. It is expected to have positive association between inflation and currency holdings because due to rise in inflation people tend to hold more money to maintain the same living standards they were living before. Coefficient of the tax to GDP ratio is positive and significant at 1 percent level, which implies that higher the tax rate, higher will be the currency holdings. Value of coefficient exceeds unity, i.e., 1.745,¹¹ which shows that one percent change in the tax to GDP ratio leads to change in currency ratio by 1.745. Similar to Equation 1, negative and significant association between the banking services and currency ratio implies that the improvement in banking services lower the demand for currency holding. Coefficient of growth shows that higher level of economic growth is expected to decrease the demand for currency holdings significantly.¹² Similar to Equation 1, dummy variable is highly significant, which supports the impact of *hundi* and other illegal transactions through foreign currency accounts. Coefficient of the inflation shows significant positive association between the currency holdings and the inflation rate. R^2 is 0.73 and the F -statistic is also significant which implies that the explanatory variables are significantly explaining the dependent variable. DW shows no serious problem of autocorrelation.

¹¹The coefficient of tax to GDP ratio is different from Kemal (2003) and Equation 1.

¹²Coefficient of growth was insignificant in Kemal (2003) but it is significant in the present study in both Equation 1 and Equation 2. However, the value of the coefficient is higher in Equation 2 than in Equation 1 and in Kemal (2003).

Equation 3

In Equation 3 the coefficient of the tax to GDP ratio is positive and significant at 5 percent level, which implies that increase in taxes forces the consumers to hold more currency to maintain the same level of living standards as he/she was enjoying before the change in tax rates. Similar to Equation 2, value of the coefficient exceeds unity, i.e., 1.159, which shows that one percent change in the tax to GDP ratio leads to change in currency ratio by 1.159. Similar to Equation 1 and 2, dummy variable is significantly affecting the currency ratio. Coefficients of the lagged dependent variable and inflation are positive and highly significant, which implies that both variables have significant impact on the behaviour of people to hold more currency. R^2 is 0.75 and the F -statistic is also significant which implies that the explanatory variables are significantly explaining the dependent variable. Value of h-test shows no serious problem of autocorrelation.

5.1. Estimates of the Underground Economy

The estimates of the underground economy and tax evasion are reported in Table 3. The size of the underground economy and tax evasion differs for each estimated equation because these values are very sensitive to the values of estimated coefficient. These estimates should not be taken as exact measures but it can be used as overall trend.

Equation 1

The estimates of the underground economy from Equation 1 show that the underground economy was 16.3 percent of the GDP in the base year (1974). It increased to 24.8 percent in 1984 but in 1991 it declined to 19.7 percent. However, between 1991 and 1998 the underground economy increased rapidly; it was 38.7 percent in 1998 but declined to 28.5 percent of GDP in 1999. In the next four years it increased to 35.7 percent and again declined to 31.4 percent in 2005.

Equation 2

The estimates of the underground economy from Equation 2 show that the underground economy was 38.02 percent of the GDP in the base year (1974). It increased to 49.29 percent in 1984 but in 1991 it declined to 36.09 percent. However, between 1991 and 1997 the underground economy increased rapidly; it was 74.92 percent in 1997 but declined to 46.1 percent of GDP by 1999. In 2003 it again increased to 68.2 percent and again declined to 64.8 percent in 2005.

Equation 3

The estimates of the underground economy from Equation 3 show that the underground economy was 22.4 percent of the GDP in the base year (1974).

It increased to 34.7 percent in 1984 but in 1991 it declined to 27.3 percent. However, between 1991 and 1998 the underground economy increased rapidly; it was 57.1 percent in 1998 but declined to 40.7 percent of GDP in 1999. In 2003 it again increased to 51 percent and then declined to 44.3 percent in 2005.

5.2. Estimates of the Tax Evasion

Estimates of tax evasion¹³ follow the trends similar to the estimates of the underground economy. Similar to the estimates of the underground economy, these estimates should not be taken as exact measures of tax evasion rather these estimates can be used as over all trend.

Equation 1

The estimates of tax evasion from Equation 1 show that tax evasion was 1.74 percent of the GDP in the base year (1974). It increased to 3.46 percent in 1982 and 3.7 percent in 1987 but declined to 2.4 percent in 1991. However, between 1991 and 1998 tax evasion increased rapidly; it was 4.86 percent in 1998 but declined to 3.59 percent in 1999. In 2003 it increased to 4.75 percent and then declined to 3.88 percent in 2005.

Equation 2

The estimates of tax evasion from Equation 2 show that tax evasion was 4.04 percent of GDP in the base year (1974). It increased to 6.84 percent in 1982 and 7.32 percent in 1987 but declined to 4.34 percent in 1991. However, between 1991 and 1997 tax evasion increased rapidly; it was 9.6 percent in 1997 but declined to 5.82 percent in 1999. In 2003 it again increased to 9.1 percent and then declined to 8 percent in 2005.

Equation 3

The estimates of tax evasion from Equation 2 show that tax evasion was 2.38 percent of the GDP in the base year (1974). It increased to 4.83 percent in 1982 and 5.2 percent in 1987 but decline to 3.29 percent in 1991. However, between 1991 and 1998 tax evasion increased rapidly; it was 7.2 percent in 1998 but declined to 5.13 percent in 1999. In 2003 it again increased to 6.78 percent and then declined to 5.48 percent in 2005.

These trends show that estimates of the underground economy and tax evasion change with the change in specification of the model. The main significant variable in all the three equations is tax to GDP ratio; the entire estimates of the underground economy and the tax evasion are based on this

¹³The estimates of tax evasion are derived as based on a strong assumption that incomes in the underground economy would have been taxed at the same rate as incomes in the formal economy.

single variable. Now we will check that whether trend of the underground economy and tax evasion is the same using the three equations. For this purpose we plot graphs of underground economy and tax evasion. All the three graphs (Graph 2, Graph 3, and Graph 4) show similar trend that the underground economy increased rapidly from 1991 to 1998 and then declined in 1999. It increased again between 1999 and 2003 and declined in 2005. Similarly, the graphs of tax evasion (Graph 5, Graph 6, and Graph 7) show that tax evasion increased rapidly from 1991 to 1998 and then declined in 1999. It increased again between 1999 and 2003 and declined in 2005.

Kemal (2003) attributed the rapid increases in the underground economy and tax evasion during 1991 and 1998 to rise in private investment level which increases the overall economic activity (formal and informal) and increase in smuggling. On the other hand increase in private sector credit and increase in the growth rate of formal GDP in the last three years did not increase in the underground economy, which may imply the better governance policies of the Government.

5.3. Measuring the Size of the Underground Economy and Tax Evasion

The National Tax Reform Commission, NTRC, (1986, p103 – p104) estimated the underground economy and tax evasion for the year 1984 – 85, based on a rigorous methodology, which are the best estimates available till now. To estimate the exact amount of the underground economy and tax evasion in Pakistan we used the ratio of these estimates to the estimated values we have obtained for the same year (i.e., 1984 – 85) to project the estimates of the underground economy and tax evasion. The results are reported in Table 4, which show that the size of the underground economy ranges between Rs. 2.91 trillion – Rs. 3.34 trillion (54.6 percent of GDP to 62.8 percent of GDP respectively) in 2005 and tax evasion ranges between Rs. 302 billion – Rs. 347 billion (5.7 percent of GDP to 6.5 percent of GDP respectively) in 2005.

6. CONSEQUENCES OF THE UNDERGROUND ECONOMY AND TAX EVASION

Rise in the underground economy decreases the state revenues, which in turn reduces the quality and quantity of publicly provided goods and services [Schneider and Enste (2000)]. The loss of revenues is then either filled through increase in tax rates or by increase in price of inelastic goods, i.e., inflation tax. To reduce the prices in the country Government then reduces the money supply and increases the interest rate, which reduces the credit creation and the level of investment. Consequently, the overall economic activity declines.

As discussed earlier that increase in the underground economy creates problems for the policymakers especially to formulate monetary and fiscal policies. The public sector faces the challenge of substantially reforming the social security and tax systems to reduce the budget deficit at the minimum possible level without compromising at the welfare of the people of the country. High tax rates and regulatory burdens cause an increase in the underground economy, which puts additional pressure on public finance, resulting in even higher tax rates and people start evading taxes more than they were evading before. Moreover, even if government reduces the tax rates, people will be reluctant to report their income earned from informal activities. This could be due to two factors (i) unwillingness to pay,¹⁴ and (ii) fear or lack of trust.¹⁵

In the absence of tax evasion our budget balance could have been surplus for many years. Table 5 shows budget deficit and tax evasion (computed using Equation 1) since 1976. It shows that in certain years, i.e., 1995–97 and 2000–2005, if tax evasion was zero the budget balance could have been surplus. However, it is straight forward that even if the budget balance could not be surplus, the burden of the budget deficit would be lessened and we would need to borrow less.

The role of monetary policy is to enhance growth through increase in investment. In the presence of high and increasing underground economy it is a big question mark that how much money supply is needed to get better GDP growth. For instance, if 30 percent of the money supply goes to the activities in the underground economy, and the government increases money supply by 5 percent then 1.5 percent goes into the underground economic activities. However, there might not be any difficulty in monetary policy formulation if the underground economy is growing at a constant rate, i.e., ratio of underground economy to formal GDP is constant. But at the increasing rate of the expansion of the underground economy it is difficult, which thus creates problems for the authorities to achieve their desired objectives, i.e., to increase GDP growth at a certain level though increase in money supply.

¹⁴They can save the amount of money that they are supposed to pay in the forms of taxes.

¹⁵They do not trust the government and think that they might increase the tax rates again in the following years, and by paying taxes they will be registered in the tax net and can be penalised afterwards if they evade taxes.

1988	8.5	4.6	2003	3.7	7.1
1989	7.4	4.6	2004	2.4	6.3
1990	6.5	4.0	2005	3.3	5.8

It is straight forward that these activities should be cut down because they weaken the system. There could be various possibilities such as increase the number of legal documentation, strengthening the institutions, better governance, improvement in tax payer records, prohibit smuggling through tariff rationalisation or free trade is even better, and efficiency wages could be good to prohibit people both from shirking on the jobs and taking bribe.

7. FORMAL ECONOMY AND THE UNDERGROUND ECONOMY

Kemal (2003) stated that when formal activities are increasing underground economic activities are also increasing, which implies that these two move parallel. It associates increase in the underground economy and tax evasion during 1991 and 1998 with increase in the formal economy and decline in the underground economy after 1998 to decline in smuggling and more importantly low level of economic activity, i.e., decline in the formal economy. This argument was strongly supported by the 97.35 percent correlation found between the underground economy and the formal economy. In the present study the correlation between the formal and the underground economy is also significantly high; more than 94 percent.

Theoretically we can say that when formal economy increases the underground economy also increases, therefore, there is a positive relationship between these two. For example, when an industrialist hires some permanent and contractual labour he is liable to pay taxes on the number of permanent employees only. So he can evade/avoid taxes on contractual or piece rate workers.¹⁶ Therefore, when there is low level of economic activity he/she hires

¹⁶This is one of the reasons that employers avoid giving exact figures of their employees as observed during various field works for different surveys/projects.

less contractual or piece rate workers and hence there will be less evasion of taxes and lesser underground economy. But when there is an increase in the economic activity he/she hires more contractual or piece rate workers. He has the opportunity then to show even his permanent employees as contractual labour and evade taxes easily which contributes to the growth of the underground economy.

Substantial reduction of the underground economy leads to a significant increase in tax revenues and therefore to greater quantity and quality of public goods and services, which ultimately can stimulate economic growth [Schneider and Enste (2000)]. However, it is not true that sometimes when decrease in the underground economy is accompanied by decline in overall economic activity then both tax evasion and tax collected from legal activities will go down and total tax revenues will go down as well. In this case, to increase tax revenues Governments take measures to increase the tax base by including more people in the tax net. Proper auditing of the taxpayers is also an important part of it.

Loayza (1996) concludes that in economies where (i) the statutory tax burden is larger than optimal, and (ii) enforcement of compliance is too weak, the increase in the relative size of the underground economy generates a reduction in economic growth. On the other hand, Schneider (1998) shows that over 66 percent of earnings in the underground economy are immediately spent in the official sector, with positive effects on economic growth and indirect tax revenues.

Corruption is one of its own kind of the underground economic activity. Is it good or bad for the GDP growth is certainly a question of concern. There are certain economies/people/researchers who want corruption free society. However, researchers also argue that it smoothens the process of growth and development. Romer (1994) suggested that corruption, as a tax on ex post profits, may in general stimulate the entry of new goods or technology which requires an initial fixed cost investment.

Mauro (1995) finds a significant negative correlation between a corruption index and the investment rate or rate of GDP growth.¹⁷ Johnson, Kaufmann, and Lobatón (1998) find a significant negative relationship between corruption and GDP growth but the relationship becomes insignificant if the underground economy is used as an independent variable. Adam and Ginsburgh (1985) find positive relationship between the growth of the underground economy and the official economy.

Aman (2006) concluded that the growth maximising level of corruption is not necessarily equal to zero and that corruption leads to better income distribution.¹⁸ He calculated the threshold level of corruption as 8.3 (index

¹⁷Negative correlation implies that increase in corruption leads to higher GDP growth.

¹⁸Though there are several other ways of improving income distribution and this could be a good finding but it cannot be adopted as a policy to improve income distribution.

ranges from 0 – 12; 0 means no corruption) and Pakistan’s corruption index was 3 in 2003 and it was maximum during 1997 and 1998 at 6. However, this does not imply that we still have space to increase our level of corruption.

Y-R (2003) using simple OLS regression concluded that both tax evasion and the underground economy have significant negative impact on the formal economy. It may be noted that their results could be spurious and one really needs to take care of this problem.

The evidence shows that the relationship between the underground economy and the formal economy shows ambiguous results. In the short run the underground economy may have positive impact on formal economy but in the long run, because it weakens the system, it may affect the formal economy adversely. Long run relationship is checked using Johansen cointegration analysis.¹⁹

Table 6 shows the results of stationarity test (both the variables are taken in log form). Philip-Perron test is applied on log of the underground economy because of structural break in 1998 when underground economy declined to very low level. KPSS²⁰ test is also used for further confirmation of the unit root process in the variables. ADF and KPSS tests are applied on log of the nominal GDP. The results show that both the variables are non-stationary but integrated of orders one, which implies that there may exist long run relationship between the two variables.

Table 6

<i>Results of Stationarity</i>			
	ADF	PP	KPSS
<i>ue</i>		-1.79	0.75*
Δue		-5.10*	0.27
<i>Y</i>	-1.24		0.70**
Δy	-3.35*** (-3.31**)		0.44

Note: *, **, *** Represent 1, 5, and 10 percent level of significance respectively.

Value in parenthesis show ADF value with constant but no trend.

Johansen test is applied at different lags and lags selection is based on minimum value of AIC.²¹ It is found that AIC is minimum at 5 lags when we use both constant and trend in cointegrating and VEC equation. The trace and maximum eigenvalues test show that rank is equal to one (Table 7), which implies that both variables are linearly dependant on each other.

¹⁹See Enders (2004) for the detailed methodology.

²⁰Significant KPSS value shows unit root (non-stationary) and insignificant shows stationary variables.

²¹For more details on AIC and lags selection criteria, see Enders (2004).

Trace and Eigenvalues Test

No. of Cointegrating Vectors	Unrestricted Cointegration Rank Test (Trace)			
	Eigenvalues	Trace Statistic	Critical Value (5%)	Probability**
None *	0.78	40.37	18.40	0.00
At most 1	0.06	1.58	3.84	0.21

No. of Cointegrating Vectors	Maximum Eigenvalues			
	Eigenvalues	Trace Statistic	Critical Value (5%)	Probability**
None *	0.78	38.79	17.15	0.00
At most 1	0.06	1.58	3.84	0.21

* Denotes rejection of the hypothesis at the 5 percent level of significance.

**MacKinnon-Haug-Michelis (1999) *p*-values.

Table 8 shows significant positive long run association between the underground economy and the nominal formal GDP, which rejects our null hypothesis. This implies that even in the long run the formal economy and the underground economy moves together and have positive association.

Table 8

Results of Cointegration and Error Correction

Variables	Coefficients
y_{t-1}	1.00
ue_{t-1}	-1.22
	[-9.33]*
Trend	0.05
Constant	0.90

Coefficient	Error Correction Mechanism	
	Δy	Δue

the formal economy in the short run. It is also shown that the underground economy is positive and significantly affected by its own lags (1 and 2), which implies that if the underground economy starts increasing, it continuously increases for at least 2 years and vice versa.

8. SUMMARY AND CONCLUSIONS

The main objective of the paper is to estimate the size of the underground economy and tax evasion using fresh data and explore the impact of the underground economy on formal GDP. The study also describes the consequences of the underground economy.

Using the NTRC (1986) estimates of the underground economy and tax evasion for the year 1984-85, estimates of the size of the underground economy and tax evasion have been computed. The underground economy ranges between Rs 2.91 trillion—Rs 3.34 trillion (54.6 percent of GDP to 62.8 percent of GDP respectively) in 2005 and tax evasion ranges between Rs 302 billion—Rs 347 billion (5.7 percent of GDP to 6.5 percent of GDP respectively) in 2005.

Underground economy and tax evasion was increasing very rapidly in the early eighties but the rate of increase was more in the nineties and was maximum in 1998. However, in 1999 it declined but then again started rising till 2003. However, it started decreasing after 2003.

Univariate causality has been found between the underground economy and the formal economy. It shows that the underground economy is causing the formal economy but formal economy is insignificant in explaining the movements in the underground economy. It is also concluded that in the long run underground economy and formal economy are positively associated.

Rise in the underground economy creates problems for the policymakers to formulate the policies especially the monetary and fiscal policies. It is concluded that if there was no tax evasion budget balance for certain years might be positive and we would not need to borrow as much as we had borrowed. There could be various possible ways to cut down these activities which must need strict measures such as: increase the number of legal documentation, strengthening the institutions, better governance, decrease the number of regulations which prohibit people to work in the formal economy, improvement in tax payer records, restrict smuggling through tariff rationalisation or free trade is even better, and efficiency wages could be good to prevent people both from shirking on the jobs and taking bribe. In the long run we can bring awareness to the people on the benefits of paying taxes which improves the tax morale of the people.

Increase in the underground economy is mostly associated with the tax burdens and intensity of regulations. It is difficult for the authorities to broaden the tax base in a very short period of time but it is the most necessary thing to do, which should have been done many years ago. It would be good to impose tax by analysing the tax Laffer curve, i.e., the optimal tax rate. Government should ensure that regulatory laws are implemented properly as they were made and reduce the number of regulations which prohibit people to work in the official economy.

Future research may include strength of institutions and other relevant variables in explaining that what mainly causes the underground economy. One can also check the association between the underground economy and different sectors of GDP.
