October 22, 2009

Abstract

In this paper, we investigate the computation of the moments of the compound Poisson sums with discounted claims when introducing dependence between the interclaim time and the subsequent claim size. The dependence structure between the two random variables is defined by a Farlie-Gumbel-Morgenstern copula. Assuming that the claim distribution has finite moments, we give expressions for the first and the second moments and then we obtain a general formula for any mth order moment. The results are illustrated with applications to premium calculation, moment matching methods, as well as inflation stress scenarios in Solvency II.

Keywords : *Compound Poisson process, Discounted aggregate claims, Moments, FGM copula, Constant interest rate.*

1   Introduction

We consider a continuous-time compound renewal risk model for an insurance portfolio and we define the compound process of the discounted claims X_i, $i = 1, 2, ...$ occurring at time T_i, $i = 1, 2, ...$ by $\underline{Z} = \{Z(t), t \geq 0\}$ with

$$Z(t) = \begin{cases} \sum_{i=1}^{N(t)} e^{-\delta T_i} X_i, & N(t) > 0 \\ 0, & N(t) = 0, \end{cases}$$

where $\underline{N} = \{N(t), t \geq 0\}$ is an homogeneous Poisson counting process and δ the constant net interest rate. In actuarial risk theory, it is assumed that the claim amounts X_i, $i = 1, 2, ...$ are independent and identically distributed (i.i.d.) random variables (r.v.'s) and the interclaim times $W_1 = T_1$ and $W_j = T_j - T_{j-1}$, $j = 2, 3, ...$ are also i.i.d. r.v.'s. The r.v.'s X_i' and W_i, $i = 1, 2, ...$ are

[‡]*École d'Actuariat, Université Laval, Québec, Canada*

classically supposed independent. This last assumption also implies that $X_i, i = 1, 2, ...$ are independent from $\underline{N}$. This risk process has been used in ruin theory by many authors such as Taylor (1979), Waters (1983), Delbaen and Haezendonck (1987), Willmot (1989), Sundt and Teugels (1995) and more recently Kalashnikov and Konstantinides (2000), Yang and Zhang (2001) and Tang (2005). They mainly focused on the ruin probability and related ruin measures.

Only a few recent works deal with the distribution of the aggregate discounted claims $Z(t)$. Léveillé and Garrido (2001a) provide the first two moments of this process. These first two moments were also obtained in Jang (2004) using martingale theory. This result has since been generalized by relaxing some of the classical assumptions presented above. Léveillé and Garrido (2001b) and Léveillé et al. (2009) derived recursive formulas for all the moments of the aggregate discounted claims considering a compound renewal process where $\underline{N}$ is not necessarily a Poisson process. In Jang (2007), the Laplace transform of the distribution of a jump diffusion process and its integrated process is derived and used to obtain the moments of the compound Poisson process $Z(t)$. Kim and Kim (2007) and Ren (2008) studied the discounted aggregate claims in a Markovian environment which modulates the distributions of the interclaim times and claim sizes for the former and the distribution of the interclaim times for the latter. They both provided the Laplace transform of the distribution of the discounted aggregate claims and then gave expressions for its first two moments.

The aggregation of discounted random variables is also used in many other fields of application. For example, it can be used in warranty cost modeling, see Duchesne and Marri (2009), or in reliability in civil engineering, see van Noortwijk and Frangopol (2004) or Porter et al. (2004).

In this paper, we want to introduce some dependence between the interclaim times and the subsequent claim amounts. In risk theory, this dependence has already been explored. For example, Albrecher and Boxma (2004) supposed that if a claim amount exceeds a certain threshold, then the parameters of the distribution of the next interclaim time is modified. In Albrecher and Teugels (2006) the dependence is introduced with the use of an arbitrary copula. Conversely to Albrecher and Boxma (2004), Boudreault et al. (2006) assumed that if an interclaim time is greater than a certain threshold then the parameters of the distribution of the next claim amount is modified. In a similar dependence model, but with more freedom in the choice of the copula between each interclaim time and the subsequent claim amount, Asimit and Badescu (2009) consider a constant force of interest and heavy-tailed claim amounts. Dependence concepts used in Boudreault et al. (2006) were then extended in Biard et al. (2009) where they suppose that the distribution of a claim amount has its parameters modified when several preceding interclaim times are all greater or all lower than a certain threshold. All these papers were interested in finding exact expressions or approximations for some ruin measures such as the ruin probability or the Gerber-Shiu function.

In our study, this assumption of independence between the claim amount X_j and the interclaim time W_j is relaxed to allow $\{(X_j, W_j), j \in \mathbb{N}^+\}$ to form a sequence of i.i.d. random vectors distributed as the canonical random vector (X, W) in which the components may be dependent. We follow the idea of Albrecher and Teugels (2006) supposing that dependence is introduced by a copula between an interclaim time and its subsequent claim amount. More specifically, we use the Farlie-Gumbel-Morgenstern (FGM) copula which is defined by

$$C_\theta^{FGM}(u, v) = uv + \theta uv (1 - u)(1 - v), \tag{1}$$

2

for $(u, v) \in [0, 1] \times [0, 1]$ and where the dependence parameter θ takes value in $[-1, 1]$. While there are a large number of copula families, we choose the FGM copula because it offers the advantage of being mathematically tractable as it is illustrated in Cossette et al. (2009). Even if the FGM copula introduces only light dependence, it admits positive as well as negative dependence between a set of random variables and includes the independence copula when $\theta = 0$. It is also known that the FGM copula is a Taylor approximation of order one of the Frank copula (see Nelsen (2006), page 133), Ali-Milkhail-Haq copula and Plackett copula (see Nelsen (2006), page 100).

The paper is structured as follows. In the second section, we present the model of the continuous time compound Poisson risk process that we use and give some notation. The first moment, the second moment and then a generalization to the mth moment are derived in Section 2. Applications to premium calculation, moment matching methods and Solvency II are given in the third section. In particular, we show how our method may be used to determine Solvency Capital Requirements and to perform part of Own Risk and Solvency Assessment (ORSA) analysis in Solvency II for some cat risks and inflation risk.

2 The model

As explained in the introduction, we consider the continuous-time compound Poisson process $\underline{Z} = \{Z(t), t \geq 0\}$ of the discounted claims $X_1, ..., X_{N(t)}$ occurring at times $T_1, ..., T_{N(t)}$ with

$$Z(t) = \begin{cases} \sum_{i=1}^{N(t)} e^{-\delta T_i} X_i, & N(t) > 0 \\ 0, & N(t) = 0, \end{cases}$$

where $E[X_i^k] < \infty$ for $i = 1, 2, ...$

We introduce a specific structure of dependence based on the Farlie-Gumbel-Morgenstern copula between the ith claim amount and the ith interclaim time such that, using (1), the joint cumulative distribution function (c.d.f.) for the canonical random vector (X, W) is

$$\begin{aligned} F_{X,W}(x, t) &= C(F_X(x), F_W(t)) \\ &= F_X(x) F_W(t) + \theta F_X(x) F_W(t)(1 - F_X(x))(1 - F_W(t)), \end{aligned}$$

for $(t, x) \in \mathbb{R}^+ \times \mathbb{R}^+$ and where F_X and F_W are the marginals of respectively X and W. This dependence relation implies that $X_1, X_2, X_3, ...$ are no more independent of $\underline{N}$. Recalling the density of the FGM copula

$$c_\theta^{FGM}(u, v) = 1 + \theta(1 - 2u)(1 - 2v),$$

for $(u, v) \in [0, 1] \times [0, 1]$, the joint probability density function (p.d.f.) of (X, W) is

$$\begin{aligned} f_{X,W}(x, t) &= c_\theta^{FGM}(F_X(x), F_W(t)) f_X(x) f_W(t) \\ &= f_X(x) f_W(t) + \theta f_X(x) f_W(t)(1 - 2F_X(x))(1 - 2F_W(t)), \end{aligned}$$

where f_X and f_W are the p.d.f.'s of respectively X and W.

3

The mth moment of $Z(t)$ is denoted by $\mu_Z^{(m)}(t) = E\left[Z^{(m)}(t)\right]$ and its Laplace transform by $\widetilde{\mu}_Z^{(m)}(r)$ with $m \in \mathbb{R}^+$. We see in the next section how to derive explicit formulas for these moments.

3 Moments of the aggregate discounted claims

3.1 First moment

To derive the expression for the first moment $\mu_Z(t)$ of $Z(t)$, we condition on the arrival of the first claim

$$
\begin{aligned}
\mu_Z(t) &= E[Z(t)] \\
&= E\left[E\left[e^{-\delta s}X_1 + e^{-\delta s}Z(t-s)|W_1 = s\right]\right] \\
&= \int_0^t f_W(s)e^{-\delta s}E[X|W=s]\,ds + \int_0^t f_W(s)e^{-\delta s}\mu_Z(t-s)\,ds,
\end{aligned}
$$

where

$$
\begin{aligned}
E[X|W=s] &= \int_0^\infty x f_{X|W=s}(x)\,dx \\
&= \int_0^\infty x\{(1 + \theta(1 - 2F_X(x))(1 - 2F_W(s)))\}f_X(x)\,dx \\
&= E[X] + \theta\int_0^\infty x(2 - 2F_X(x))(1 - 2F_W(s))f_X(x)\,dx \\
&\quad -\theta\int_0^\infty x(1 - 2F_W(s))f_X(x)\,dx \\
&= E[X](1 - \theta(1 - 2F_W(s))) \\
&\quad +\theta(1 - 2F_W(s))\int_0^\infty (1 - F_X(x))^2\,dx. \tag{2}
\end{aligned}
$$

Letting

$$
E[X'] = \int_0^\infty (1 - F_X(x))^2\,dx < \int_0^\infty (1 - F_X(x))\,dx = E[X],
$$

(2) becomes

$$
E[X] + \left(E[X'] - E[X]\right)\theta(1 - 2F_W(s)). \tag{3}
$$

From (3), we can derive the following remarks. If $\theta > 0$ ($\theta < 0$) and $s < F_W^{-1}(0.5)$ ($s > F_W^{-1}(0.5)$, respectively), then $E[X|W=s] < E[X]$. Conversely, if $\theta > 0$ ($\theta < 0$) and $s > F_W^{-1}(0.5)$ ($s < F_W^{-1}(0.5)$, respectively), then $E[X|W=s] > E[X]$.

We consider the case where the canonical r.v. W has an exponential distribution with mean $\frac{1}{\beta}$

4

and

$$f_W(t) = \beta e^{-\beta t}, \tag{4}$$
$$F_W(t) = 1 - e^{-\beta t}, \tag{5}$$
$$\widetilde{f}_W(s) = E\left[e^{-sW}\right] = \frac{\beta}{\beta + s}.$$

For simplification purposes, we use the expressions

$$h(s; \gamma) = \gamma e^{-\gamma s}$$
$$\widehat{h}(r; \gamma) = \frac{\gamma}{\gamma + r}$$

to derive the moments of $Z(t)$.

We obtain the following expression for $\mu_Z(t)$

$$
\begin{aligned}
\mu_Z(t) &= \int_0^t f_W(s) e^{-\delta s} E[X]\, ds + \theta\left(E[X'] - E[X]\right) \int_0^t f_W(s) e^{-\delta s}\left(1 - 2F_W(s)\right) ds \\
&\quad + \int_0^t f_W(s) e^{-\delta s} \mu_Z(t-s)\, ds \\
&= \int_0^t \beta e^{-\beta s} e^{-\delta s} E[X]\, ds + \theta\left(E[X'] - E[X]\right) \int_0^t \beta e^{-\beta s} e^{-\delta s}\left(2e^{-\beta s} - 1\right) ds \\
&\quad + \int_0^t \beta e^{-\beta s} e^{-\delta s} \mu_Z(t-s)\, ds \\
&= \int_0^t \frac{\beta}{\beta + \delta} h(s; \beta + \delta) E[X]\, ds \\
&\quad + \theta\left(E[X'] - E[X]\right) \int_0^t \frac{2\beta}{2\beta + \delta} h(s; 2\beta + \delta)\, ds \\
&\quad - \theta\left(E[X'] - E[X]\right) \int_0^t \frac{\beta}{\beta + \delta} h(s; \beta + \delta)\, ds \\
&\quad + \int_0^t \frac{\beta}{\beta + \delta} h(s; \beta + \delta) \mu_Z(t-s)\, ds. \tag{6}
\end{aligned}
$$

We take the Laplace transform on both sides of (6) and after some rearrangements, we obtain

$$
\widetilde{\mu}_Z(r) = \frac{\frac{\widehat{h}(r; \beta+\delta)}{r} \frac{\beta}{\beta+\delta} E[X] + \theta\left(E[X'] - E[X]\right) \left(\frac{2\beta}{2\beta+\delta} \frac{\widehat{h}(r; \beta+\delta)}{r} - \frac{\beta}{\beta+\delta} \frac{\widehat{h}(r; \beta+\delta)}{r}\right)}{1 - \frac{\beta}{\beta+\delta} \widehat{h}(r; \beta+\delta)} \tag{7}
$$

which is equivalent to

$$
\widetilde{\mu}_Z(r) = \frac{\frac{1}{r} \frac{\beta+\delta}{\beta+\delta+r} \frac{\beta}{\beta+\delta} E[X] + \theta\left(E[X'] - E[X]\right) \left(\frac{2\beta}{2\beta+\delta} \frac{1}{r} \frac{2\beta+\delta}{2\beta+\delta+r} - \frac{\beta}{\beta+\delta} \frac{1}{r} \frac{\beta+\delta}{\beta+\delta+r}\right)}{1 - \frac{\beta}{\beta+\delta} \frac{\beta+\delta}{\beta+\delta+r}}. \tag{8}
$$

5

Rearranging (8), we deduce

$$\widetilde{\mu}_Z(r) \;=\; \frac{\beta E[X]}{r(\delta+r)} + \theta\frac{\beta\left(E[X']-E[X]\right)}{r(2\beta+\delta+r)}. \tag{9}$$

Inverting (9), we obtain

$$\mu_Z(t) \;=\; \beta E[X]\frac{1-e^{-\delta t}}{\delta} + \theta\beta\left(E[X']-E[X]\right)\frac{1-e^{-(2\beta+\delta)t}}{2\beta+\delta}. \tag{10}$$

Notice that when the r.v.'s X and W are independent which corresponds to $\theta=0$, the expected value of the compound process of the discounted claims, noted $Z_{ind}(t)$, becomes

$$\mu_{Z_{ind}}(t) \;=\; \beta E[X]\frac{1-e^{-\delta t}}{\delta}.$$

3.2   Second moment

As for the first moment of the discounted total claim amount, we condition on the arrival of the first claim to obtain the second moment of $Z(t)$

$$
\begin{aligned}
\mu_Z^{(2)}(t) \;=\;& E\left[E\left[(e^{-\delta s}X_1 + e^{-\delta s}Z(t-s))^2|W_1=s\right]\right]\\
\;=\;& \int_0^t f_W(s)\,e^{-2\delta s}E\left[X^2|W=s\right]ds + 2\int_0^t f_W(s)\,e^{-2\delta s}E\left[X|W=s\right]\mu_Z(t-s)\,ds\\
&+ \int_0^t f_W(s)\,e^{-2\delta s}\mu_Z^{(2)}(t-s)\,ds.
\end{aligned}
$$

Similarly as in (2), we have

$$
\begin{aligned}
E\left[X^2|W=s\right] \;=\;& E\left[X^2\right]\left(1-\theta\left(1-2F_W(s)\right)\right)\\
&+\theta\left(1-2F_W(s)\right)\int_0^\infty 2x\left(1-F_X(x)\right)^2 dx\\
\;=\;& E\left[X^2\right] + \left(E\left[\left(X'\right)^2\right]-E\left[X^2\right]\right)\theta\left(1-2F_W(s)\right),
\end{aligned}
$$

where

$$E\left[\left(X'\right)^2\right] = \int_0^\infty 2x\left(1-F_X(x)\right)^2 dx < \int_0^\infty 2x\left(1-F_X(x)\right)dx = E\left[X^2\right].$$

We find the following expression for $\mu_Z^{(2)}(t)$

$$
\begin{aligned}
\mu_Z^{(2)}(t) &= \int_0^t f_W(s)\, e^{-2\delta s} E\left[X^2\right] ds + \theta\left(E\left[(X')^2\right] - E\left[X^2\right]\right) \int_0^t f_W(s)\, e^{-2\delta s}\left(1 - 2F_W(s)\right) ds \\
&\quad + 2\int_0^t f_W(s)\, e^{-2\delta s} E\left[X\right]\mu_Z(t-s)\, dsds \\
&\quad + 2\theta\left(E\left[(X')\right] - E\left[X\right]\right) \int_0^t f_W(s)\, e^{-2\delta s}\left(1 - 2F_W(s)\right)\mu_Z(t-s)\, ds + \int_0^t f_W(s)\, e^{-2\delta s}\mu_Z^{(2)}(t-s)\, ds \\
&= \int_0^t \frac{\beta}{\beta + 2\delta} h(s; \beta + 2\delta) E\left[X^2\right] ds \\
&\quad + \theta\left(E\left[(X')^2\right] - E\left[X^2\right]\right) \int_0^t \left(\frac{2\beta}{2\beta + 2\delta} h(s; 2\beta + 2\delta) - \frac{\beta}{\beta + 2\delta} h(s; \beta + 2\delta)\right) ds \\
&\quad + 2\int_0^t \frac{\beta}{\beta + 2\delta} h(s; \beta + 2\delta) E\left[X\right]\mu_Z(t-s)\, ds \\
&\quad + 2\theta\left(E\left[(X')\right] - E\left[X\right]\right) \int_0^t \left(\frac{2\beta}{2\beta + 2\delta} h(s; 2\beta + 2\delta) - \frac{\beta}{\beta + 2\delta} h(s; \beta + 2\delta)\right)\mu_Z(t-s)\, ds \\
&\quad + \int_0^t \frac{\beta}{\beta + 2\delta} h(s; \beta + 2\delta)\mu_Z^{(2)}(t-s)\, ds.
\end{aligned}
\tag{11}
$$

We take the Laplace transform on both sides of (11) and after some rearrangements, we obtain

$$
\begin{aligned}
\tilde{\mu}_Z^{(2)}(r) &= \frac{1}{1 - \frac{\beta}{\beta + 2\delta}\widehat{h}(r; \beta + 2\delta)}\Bigg[\frac{\widehat{h}(r; \beta + 2\delta)}{r}\frac{\beta}{\beta + 2\delta} E[X^2] \\
&\quad + \theta\left(E[(X'^2] - E[X^2])\right) \left(\frac{2\beta}{2\beta + 2\delta}\frac{\widehat{h}(r; 2\beta + 2\delta)}{r} - \frac{\beta}{\beta + 2\delta}\frac{\widehat{h}(r; \beta + 2\delta)}{r}\right) \\
&\quad + 2E[X]\frac{\beta}{\beta + 2\delta}\widehat{h}(r; \beta + 2\delta)\tilde{\mu}_Z(r) \\
&\quad + 2\theta\left(E\left[X'\right] - E[X]\right) \left(\frac{2\beta}{2\beta + 2\delta}\hat{h}(r; 2\beta + 2\delta) - \frac{\beta}{\beta + 2\delta}\widehat{h}(r; \beta + 2\delta)\right)\tilde{\mu}_Z(r)\Bigg],
\end{aligned}
$$

which becomes

$$
\begin{aligned}
\tilde{\mu}_Z^{(2)}(r) &= \frac{\beta E[X^2]}{r(2\delta + r)} + \theta\frac{\beta\left(E\left[(X'^2] - E[X^2]\right)\right)}{r(2\beta + 2\delta + r)} + 2\frac{\beta E[X]}{2\delta + r}\tilde{\mu}_Z(r) + 2\theta\frac{\beta\left(E[X'] - E[X]\right)}{2\beta + 2\delta + r}\tilde{\mu}_Z(r) \\
&= \frac{\beta E[X^2]}{r(2\delta + r)} + \theta\frac{\beta\left(E\left[(X'^2] - E[X^2]\right)\right)}{r(2\beta + 2\delta + r)} + 2\frac{\beta E[X]}{2\delta + r}\left(\frac{\beta E[X]}{r(\delta + r)} + \theta\frac{\beta\left(E[X'] - E[X]\right)}{r(2\beta + \delta + r)}\right) \\
&\quad + 2\theta\frac{\beta\left(E[X'] - E[X]\right)}{2\beta + 2\delta + r}\left(\frac{\beta E[X]}{r(\delta + r)} + \theta\frac{\beta\left(E[X'] - E[X]\right)}{r(2\beta + \delta + r)}\right) \\
&= \frac{\beta E[X^2]}{r(2\delta + r)} + \theta\frac{\beta\left(E\left[(X'^2] - E[X^2]\right)\right)}{r(2\beta + 2\delta + r)} + 2\frac{\beta^2 E[X]^2}{r(\delta + r)(2\delta + r)} + 2\theta\frac{\beta^2 E[X]\left(E\left[X'\right] - E[X]\right)}{r(2\beta + \delta + r)(2\delta + r)} \\
&\quad + 2\theta\frac{\beta^2 E[X]\left(E\left[X'\right] - E[X]\right)}{r(\delta + r)(2\beta + 2\delta + r)} + 2\theta^2\frac{\beta^2\left(E\left[X'\right] - E[X]\right)^2}{r(2\beta + \delta + r)(2\beta + 2\delta + r)}.
\end{aligned}
\tag{12}
$$

7

This last Laplace transform is a combination of terms of the form

$$\tilde{f}(r) = \frac{1}{r(\alpha_1 + r)(\alpha_2 + r)...(\alpha_n + r)},$$

with f a function defined for all non-negative real numbers. As described in the proof of Theorem 1.1 in Baeumer (2003), each of these terms can be expressed as a combination of partial fractions such as

$$\tilde{f}(r) = \gamma_0 \frac{1}{r} + \gamma_1 \frac{1}{\alpha_1 + r} + \gamma_2 \frac{1}{\alpha_2 + r} + ... + \gamma_n \frac{1}{\alpha_n + r}, \tag{13}$$

where $\gamma_0 = \frac{1}{\alpha_1...\alpha_n}$ and , for $i = 1,...,n$,

$$\gamma_i = -\frac{1}{\alpha_i} \prod_{j=1;j\neq i}^{n} \frac{1}{\alpha_j - \alpha_i}. \tag{14}$$

Since the inverse Laplace transform of $\frac{1}{\alpha_i + r}$ is $e^{-\alpha_i t}$, it is easy to inverse $\tilde{f}$ and obtain

$$f(t) = \gamma_0 + \gamma_1 e^{-\alpha_1 t} + \gamma_2 e^{-\alpha_2 t} + ... + \gamma_n e^{-\alpha_2 t}. \tag{15}$$

Using (15) in (12), it results that

$$
\begin{aligned}
\mu^{(2)}(t) =\ & \beta E[X^2]\left(\frac{1}{2\delta} - \frac{e^{-2\delta t}}{2\delta}\right) + \theta\beta\left(E\left[(X'^2] - E[X^2]\right)\left(\frac{1}{2\beta + 2\delta} - \frac{e^{-(2\beta + 2\delta)t}}{2\beta + 2\delta}\right)\right. \\
& + 2\beta^2 E[X]^2 \left(\frac{1}{2\delta^2} - \frac{e^{-\delta t}}{\delta^2} + \frac{e^{-2\delta t}}{2\delta^2}\right) \\
& + 2\theta\beta^2 E[X]\left(E[X'] - E[X]\right)\left(\frac{1}{2\delta(2\beta + \delta)} - \frac{e^{-(2\beta + \delta)t}}{(2\beta + \delta)(-2\beta + \delta)} + \frac{e^{-2\delta t}}{2\delta(-2\beta + \delta)}\right) \\
& + 2\theta\beta^2 E[X]\left(E[X'] - E[X]\right)\left(\frac{1}{\delta(2\beta + 2\delta)} - \frac{e^{-\delta t}}{\delta(2\beta + \delta)} + \frac{e^{-(2\beta + 2\delta)t}}{(2\beta + 2\delta)(2\beta + \delta)}\right) \\
& + 2\theta^2\beta^2 \left(E[X'] - E[X]\right)^2 \left(\frac{1}{(2\beta + \delta)(2\beta + 2\delta)} - \frac{e^{-(2\beta + \delta)t}}{\delta(2\beta + \delta)} + \frac{e^{-(2\beta + 2\delta)}}{\delta(2\beta + 2\delta)}\right).
\end{aligned} \tag{16}
$$

3.3 mth moment

We now generalize the previous results to the mth moment of the discounted total claim amount. Conditioning on the arrival of the first claim leads to

$$\mu_Z^{(m)}(t) = \int_0^t f_W(s) e^{-m\delta s} E[X^m | W = s] ds + \sum_{j=1}^{m-1} \binom{m}{j} \int_0^t f_W(s) e^{-m\delta s} E[X^j | W = s] \mu_Z^{(m-j)}(t-s) ds$$

$$+ \int_0^t f_W(s) e^{-m\delta s} \mu_Z^{(m)}(t-s) ds.$$

For the Laplace transform of $\mu_Z^{(m)}(t)$, we find

$$\widetilde{\mu}_Z^{(m)}(r) = \frac{1}{1 - \frac{\beta}{\beta + m\delta} \widehat{h}(r; \beta + m\delta)} \left[\frac{\widehat{h}(r; \beta + m\delta)}{r} \frac{\beta}{\beta + m\delta} E[X^m] \right.$$

$$+ \theta \left(E[(X')^m] - E[X^m] \right) \left(\frac{2\beta}{2\beta + m\delta} \frac{\widehat{h}(r; 2\beta + m\delta)}{r} - \frac{\beta}{\beta + m\delta} \frac{\widehat{h}(r; \beta + m\delta)}{r} \right)$$

$$+ \sum_{j=1}^{m-1} \binom{m}{j} E[X^j] \frac{\beta}{\beta + m\delta} \widehat{h}(r; \beta + m\delta) \widetilde{\mu}_Z^{(m-j)}(r) + \theta \sum_{j=1}^{m-1} \binom{m}{j} \left(E[(X')^j] - E[X^j] \right)$$

$$\left. \times \left(\frac{2\beta}{2\beta + m\delta} \widehat{h}(r; 2\beta + m\delta) - \frac{\beta}{\beta + m\delta} \widehat{h}(r; \beta + m\delta) \right) \widetilde{\mu}_Z^{(m-j)}(r) \right] \qquad (17)$$

which can also be expressed as follows

$$\widetilde{\mu}_Z^{(m)}(r) = \binom{m}{m} \frac{\beta E[X^m]}{r(m\delta + r)} + \binom{m}{m} \theta \frac{\beta \left(E[(X'^m] - E[X^m]) \right)}{r(2\beta + m\delta + r)} + \sum_{j=1}^{m-1} \binom{m}{j} \frac{\beta E[X^j]}{m\delta + r} \widetilde{\mu}_Z^{(m-j)}(r)$$

$$+ \theta \sum_{j=1}^{m-1} \binom{m}{j} \frac{\beta \left(E[(X'^j] - E[X^j]) \right)}{2\beta + m\delta + r} \widetilde{\mu}_Z^{(m-j)}(r).$$

Noting for $i = 1, ..., m$, $j = 1, ..., m$ and $k = 0, 1$

$$\zeta(i; j; k) = \binom{i}{j} \theta^k \frac{\beta \left(E[X^j] \right)^{1-k} \left(E[X'^j] - E[X^j] \right)^k}{k \times 2\beta + i\delta + r} = \frac{\Lambda(i; j; k)}{k \times 2\beta + i\delta + r}, \qquad (18)$$

we can rewrite $\widetilde{\mu}_Z(r)$ and $\widetilde{\mu}_Z^{(2)}(r)$ as

$$\widetilde{\mu}_Z(r) = \frac{1}{r} \left[\zeta(1, 1, 0) + \zeta(1, 1, 1) \right],$$

9

$$\tilde{\mu}_Z^{(2)}(r) = \frac{1}{r}\left[\zeta(2,2,0) + \zeta(2,2,1) + [\zeta(2,1,0) + \zeta(2,1,1)][\zeta(1,1,0) + \zeta(1,1,1)]\right]$$

$$= \frac{1}{r}\left[\zeta(2,2,0) + \zeta(2,2,1) + \zeta(2,1,0)\zeta(1,1,0) + \zeta(2,1,0)\zeta(1,1,1) + \zeta(2,1,1)\zeta(1,1,0)\right.$$

$$\left. + \zeta(2,1,1)\zeta(1,1,1)\right].$$

The term $\tilde{\mu}_Z^{(m)}(r)$ can also be expressed using (18)

$$\tilde{\mu}_Z^{(m)}(r) = \frac{1}{r}\sum_{n=1}^{m}\sum_{((i_1,j_1,k_1),\ldots,(i_n,j_n,k_n))\in\mathcal{A}_{mn}}\zeta(i_n,j_n,k_n)\times\ldots\times\zeta(i_1,j_1,k_1), \qquad (19)$$

where $\mathcal{A}_{mn} = \Big\{(i_1,j_1,k_1),\ldots,(i_n,j_n,k_n); i_1 = m, i_1+\ldots+i_n = m-1+n, i_1 > \ldots > i_n, j_1 = m+1-n,$

$j_1 + \ldots + j_n = m, j_1 \geq \ldots \geq j_n, k_. \in \{0,1\}\Big\}.$

To inverse (19), let $I\left(\zeta(i_1;j_1;k_1);\ldots;\zeta(i_n;j_n;k_n)\right)$ be the inverse Laplace transform of $\frac{1}{r}\zeta(i_1;j_1;k_1)\times$ $\ldots \times \zeta(i_n;j_n;k_n)$, for $n = 1,\ldots,m$. Using (13) and (15), we have

$$I\left(\zeta(i_1;j_1;k_1);\ldots;\zeta(i_n;j_n;k_n)\right) = \Lambda(i_1;j_1;k_1)\times\ldots\times\Lambda(i_n;j_n;k_n)\times\left(\gamma_0 + \gamma_1 e^{-\alpha(i_1;k_1)t} + \ldots + \gamma_n e^{-\alpha(i_n;k_n)t}\right)$$

with, refering to (14), $\gamma_0 = \frac{1}{\alpha(i_1;k_1)\ldots\alpha(i_n;k_n)}$ and $\gamma_u = -\frac{1}{\alpha(i_u;k_u)}\prod_{v=1;v\neq u}^{u}\frac{1}{\alpha(i_v;k_v)-\alpha(i_u;k_u)}$, $u = 1,,\ldots,n$.

It finally results that

$$\mu^{(m)}(t) = \sum_{n=1}^{m}\sum_{((i_1,j_1,k_1),\ldots,(i_n,j_n,k_n))\in\mathcal{A}_{mn}}I\left(\zeta(i_1;j_1;k_1);\ldots;\zeta(i_n;j_n;k_n)\right). \qquad (20)$$

4 Applications

As we have already discussed in the introduction, several scientific domains have recourse to discounted aggregations. We present here some applications of our results in actuarial sciences where the claim distributions are assumed to be positive and continuous.

4.1 Premium calculation

Now that we are able to compute the moments of $Z(t)$, it is possible to compute the premium related to the risk of an insurance portfolio represented by $Z(t)$. We propose here to study several premium calculation principles. The loaded premium $\Pi(t)$ consists in the sum of the pure premium

$P(t)$, which is the expected value of the costs related to the portfolio, and a loading for the risk $L(t)$ as

$$
\begin{aligned}
\Pi(t) &= P(t) + L(t) \\
&= E[Z(t)] + L(t).
\end{aligned}
$$

The loading for the risk differs according to the premium calculation principles.

Denote by $\kappa \geq 0$ the safety loading. The expected value principle defines the loaded premium as

$$
\Pi(t) = E[Z(t)] + \kappa E[Z(t)],
$$

where $L(t) = \kappa E[Z(t)]$.

The variance principle gives

$$
\Pi(t) = E[Z(t)] + \kappa Var(Z(t)),
$$

where $L(t) = \kappa Var(Z(t))$.

And finally, we introduce the standard deviation principle which is determined by

$$
\Pi(t) = E[Z(t)] + \kappa \sqrt{Var(Z(t))},
$$

where $L(t) = \kappa \sqrt{Var(Z(t))}$.

As we only need the first two moments for these exemples, we can use the equations (10) and (16) to determine the loading for the risk and then the loaded premium (see e.g. Rolski et al. (1999) for details on premium pinciples).

4.2 First three moments based approximation for the distribution of $Z(t)$

Here, we suggest to use a moment matching approximation for its distribution. As said in Tijms (1994), the class of mixture of Erlang distributions is dense in the space of positive contiuous distributions. So, we propose, as an illustration, to match the first three moments of $Z(t)$ to a mixture of two Erlang distributions of common order. This method comes from Johnson and Taaffe (1989) where a moment matching method with the first k moments is feasible for a mixture of Erlang distributions of order n is presented. The distribution function of a mixture of two Erlang distributions with respective rate parameters λ_1 and λ_2 and common order n is given by

$$
F_Y(y) = p_1 F_1(y) + p_2 F_2(y),
$$

where F_1 and F_2 are two Erlang c.d.f.'s and p_1 and p_2 their respective weight in the mixture. The p.d.f. Y is

$$
f_Y(y) = p_1 f_1(y) + p_2 f_2(y),
$$

11

where f_1 and f_2 are two Erlang p.d.f.'s. The n-th moment of the mixture of two Erlang distributions is

$$E[Y^n] = p_1 \mu_1^{(n)} + p_2 \mu_2^{(n)},$$

where $\mu_1^{(n)}$ and $\mu_2^{(n)}$ are the respective n-th moment of two Erlang distributions. Under some conditions, Theorem 3 of Johnson and Taaffe (1989) gives the parameters of the mixture of two Erlang distributions with the same order n as follows

$$\lambda_i^{-1} = \left(-B + (-1)^i \sqrt{B^2 - 4AC}\right) / (2A)$$

and

$$p_1 = 1 - p_2 = \left(\frac{\mu_1}{n} - \lambda_2^{-1}\right) / \left(\lambda_1^{-1} - \lambda_2^{-1}\right),$$

where $A = n(n+2)\mu_1 y$, $B = -\left(nx + \frac{n(n+2)}{n+1}y^2 + (n+2)\mu_1^2 y\right)$, $C = \mu_1 x$, $y = \mu_2 - \left(\frac{n+1}{n}\right)\mu_1^2$ and $x = \mu_1 \mu_3 - \left(\frac{n+2}{n+1}\right)\mu_2^2$.

For the numerical illustration, suppose that $X \sim Exp(\lambda = 1/100)$, the interclaim time distribution parameters $\beta = 1, 5$ and 10, the interest rate $\delta = 4\%$. We use three different values for the copula parameter $\theta = -1, 0, 1$ and fix the time $t = 5$. The m-th moment of X is

$$E[X^m] = \frac{1}{\lambda^m} m!.$$

As $E[(X'^m)] = \int_0^\infty m x^{m-1}(1 - F_X(x))^2 dx$, we have that

$$E[(X'^m)] = \frac{1}{(2\lambda)^m} m!.$$

The first three moments of $Z(t)$ and the matched parameters for the mixture of Erlang distributions are presented in Tables 1, 2 and 3.

θ	$\mu_Z(5)$	$\mu_Z^{(2)}(5)$	$\mu_Z^{(3)}(5)$	n	λ_1	λ_2	p_1	p_2

Table 4: VaR calculated from the Monte-Carlo simulations and the moment matching.

Remark 1 *Let $S(t) = Z(t)$ when the force of interest $\delta = 0$. As, in general for $\delta \geq 0$, we have $E[\varphi(Z(t))] \leq E[\varphi(S(t))]$ for every non-decreasing function φ, we have that $Z(t) \leq_{sd} S(t)$ where $\leq_{sd}$ designate the stochastic dominance order. Furthermore, this implies that $VaR_\alpha(Z(t)) \leq VaR_\alpha(S(t))$ for every $\alpha \in [0, 1]$.*

4.3 Solvency II internal model

The European Solvency II project is going to lay down some new regulatory requirements that every insurance company inside the European Union will have to fulfill. In addition, several other countries outside the European Union (e.g. Canada, Columbia or Mexico) are likely to use similar principles. The directive has been adopted in April 2009 and the implementation measures are in progress in order to have the new system in force on October 31st, 2012. Determination of Solvency Capital Requirement (SCR) is one of the main points of the quantitative pillar of this reform: in addition to the best estimate (which is defined as the expected present value of all potential future cash flows that would be incurred in meeting policyholders' liabilities) of liabilities and a risk margin, insurance companies and reinsurers will have to own an extra capital to cope with unfavorable events. The computation of the Solvency II standard formula for SCR is based on the 1-year 99.5%-Value-at-risk (VaR). Most often in the standard formula, it is assumed that the heaviness of the tail of the distribution of random loss X is quite moderate, and so the SCR, defined as the difference $VaR_{99.5\%}(X) - E(X)$, is replaced by a proxy $q\sigma_X$, where σ_X denotes the

13

standard error coefficient of X and q is a quantile factor which should be set at $q = 3$. Seldom, if appropriate, factor $q = 3$ may be replaced by a larger value, close to 5 for example, to take into account potential heavier tails. This is the case in particular in the current version of the Counterparty Risk module (see Consultation Paper 51 of CEIOPS). Although quantile factors may vary from one line of business to the other, it has become classical to compute the SCR in the standard formula as a multiple of the standard error coefficient of the random loss, or with stress scenarios. Even if internal models or partial internal models are being encouraged, companies will anyway have to provide the SCR computations with the standard formula as complement. Some of those partial internal models are based on a different time horizon, up to 5 or 10 years for some reinsurers. Besides, all insurers have to provide an Own Risk and Solvency Assessment (ORSA) which aims to study risks that may affect the long-term solvency of the company. Either for ORSA or for SCR computations, it may be useful to determine the first two moments of the discounted aggregate claim amount, both with constant interest rate and inflation, and in a stress scenario where inflation increases. Inflation is very low currently, but there is a clear risk that it increases quite a bit when the crisis ends. In an ORSA analysis, it would be interesting to study the impact of inflation on Best Estimate (BE) and on the SCR: what would be the BE and the SCR in three years from now if insurance risk exposure was the same as today, but inflation was much higher? This is what we investigate in Tables 6 and 7. Solvency II standard formula often uses the independence between claim amounts and the claim arrival process. In practice, for risks like earthquake risk or flood and drought risks, the next claim amount is not independent from the time elapsed before the previous claim, and this must be taken into account in partial internal models. The advantage of our method is that it remains valid for negative values of δ (as long as they are not too negative), which can be seen as the difference between the interest rate and the inflation rate. If inflation becomes larger than the interest rate, then δ becomes negative, and our method still applies for small enough values of $|\delta|$. Some other approaches are possible as cat risk is sometimes addressed directly by the means of extreme scenarios.

Here we compute the SCR in the standard formula approach and in the internal model approach for a 5-year horizon for exponentially distributed inter-claim times and Exponential and Pareto claim amount distributions. For the internal model approach, we use Equations (??) and (??) from the previous example to compute the mth moment of $Z(t)$ when the claim amounts are exponentially distributed. If the claim amount r.v. X is Pareto with c.d.f.

$$F_X(x) = 1 - \left(\frac{\gamma}{\gamma + x}\right)^{\kappa}, \ x > 0,$$

and mth moment

$$E[X^m] = \frac{\gamma^m m!}{\prod_{i=1}^{m}(\kappa - i)} \tag{21}$$

for $\gamma > 0$ and $\kappa > m$ then $E[(X'^m]$ becomes

$$E[(X'^m] = \frac{\gamma^m m!}{\prod_{i=1}^{m}(2\kappa - i)}. \tag{22}$$

Thus the mth moment of $Z(t)$ can be explicitly expressed using (10) and (16) for the first and second moments, or using (20) for greater moments. The SCR for the internal model is obtained

14

from the first moment of $Z(t)$ and a simulated VaR with Monte-Carlo method.

Let the FGM dependence parameter be -1, 0 or 1, and $\delta = 3\%$. The parameter for the inter-claim time distribution is $\beta = 2$. Assume that the claim amount r.v. $X \sim Exp(\lambda = 1/10)$ for the Exponential case and that $X \sim Pareto(\kappa = 2.5, \gamma = 15)$ for the Pareto case with the same expected value 10 but with variances respectively equal to 100 and 500. As discussed above, we set the quatile factor q for the standard formula approach at 3 for the Exponential case and at 5 for the Pareto case. The SCR's for the standard formula and the internal model approaches are presented in Table 5. Using the internal model approach, we also compute the SCR (and the Best Estimate (BE)) with inflation crises ($\delta = 1.5\%$, 0.5% or -5%) in comparison to $\delta = 3\%$ for the Pareto case. The results are shown in Table 6.

	Exponential case		Pareto case	
Copula parameter	Standard formula ($q = 3$)	Internal model	Standard formula ($q = 5$)	Internal model
$\theta = -1$	140.508	151.075	385.760	314.362
$\theta = 0$	124.703	132.149	359.987	295.574
$\theta = 1$	107.091	111.254	332.933	276.368

Table 5: Comparison between the standard formula and the internal model approaches for the SCR, 5-year time horizon.

BE	89.760	93.229	95.639	110.446
SCR	276.368	287.600	295.391	342.066

Table 6: Effect of inflation crisis for Pareto claim amounts, 5-year time horizon.

We also provide some results for the same values for δ when the time horizon is equal to 10 years and the copula parameter $\theta = 1$ in Table 7.
Finally, we also provide in Table 8 a few results with $\theta = 1$ and $\beta = 0.5$ to see the influence of parameter β and to illustrate the case where large claims occur in average every m years, with $m > 1$.
Regarding dependency between inter-claim times and claim amounts, both SCR and Best Estimate are increasing with the dependence parameter θ. This is logical as positive dependence between inter-claim times and claim amounts is a form of diversification effect. SCR are larger for Pareto claim amounts than for Exponential claim amounts, as usual. Nevertheless, Table 5 shows that the so-called internal model approach leads to higher values of SCR than the ones obtained by the

15

	$\delta = 3\%$	$\delta = 1.5\%$	$\delta = 0.5\%$	$\delta = -5\%$
$\theta = 1$

standard formula for Exponentially distributed claim amounts, while it is the opposite for Pareto distributed claim amounts. Finally, the impact of inflation cannot be neglected: in Table 8, the case where $\delta = -5\%$ (which corresponds to scenarios where the inflation rate becomes 5% larger than the interest rate) leads to more than a 50%-increase in Best Estimate and SCR, in the most favorable case where $\theta = 1$.

APPENDIX

The first two moments of the distribution of $Z(t)$ which are given by (10) and (16) respectively. The third moment is

$$\mu^{(3)}(t) = \sum_{n=1}^{3} \sum_{((i_1,j_1,k_1),...,(i_n,j_n,k_n))\in\mathcal{A}_{3n}} I\left(\zeta(i_1;j_1;k_1);...;\zeta(i_n;j_n;k_n)\right),$$

where $\mathcal{A}_{3n} = \Big\{ (i_1,j_1,k_1),...,(i_n,j_n,k_n);\ i_1 = 3,\ i_1+...+i_n = 3-1+n,\ i_1 > ... > i_n,\ j_1 = 3+1-n,$

$j_1+...+j_n = 3,\ j_1 \geq ... \geq j_n,\ k_. \in \{0,1\} \Big\}$. It can be developed as

$$
\begin{aligned}
\mu_3\,(t) \;=\; & \binom{3}{3}\beta E[X^3]\left(\frac{1}{3\delta}-\frac{e^{-3\delta t}}{3\delta}\right) + \binom{3}{3}\theta\beta\left(E[X'^3]-E[X^3]\right)\left(\frac{1}{2\beta+3\delta}-\frac{e^{-(2\beta+3\delta)t}}{2\beta+3\delta}\right) \\
