Interregional Differentials in Per Capita Real Income Change

ABNER HURWITZ AND CARLYLE P. STALLINGS,

BUREAU OF LABOR STATISTICS, DEPARTMENT OF LABOR

The relationship between regional differentials in per capita income and other economic and demographic factors has been the subject of many investigations, and considerable attention has been given to the analysis of regional trends in income payments. Lack of information about regional price movement and interregional differences in price levels has precluded the analysis of differentials in "real" income payments. Most analytical studies, therefore, have been developed in terms of regional trends and levels relative to the national average.¹

This paper attempts the development of state and regional price indexes appropriate for adjusting current dollar state income payments for geographical differences in the movement of prices over time and presents estimated state per capita income adjusted by these indexes for price change over a twenty-five-year period. Indexes based on the deflated per capita income series are indicators of regional change in the purchasing power of per capita income to buy goods and services, pay taxes, and save, and offer oppor-

NOTE: The estimated state consumer price indexes presented in this paper are not to be taken as official figures of the Bureau of Labor Statistics. Although the Bureau made clerical and professional staff time available for this work, the authors take full personal responsibility for the results.

The authors wish to thank the Bureau and the National Industrial Conference Board for assistance in providing comprehensive records of their index material.

with the two major price series—the Bureau of Labor Statistics consumer price index (CPI) and the Department of Agriculture prices paid by farmers (PPF) for commodities used in family living.

CHART 1

Estimated Consumer Price Indexes, United States, 1929–1953

STATE URBAN PRICE INDEXES

In estimating urban price indexes for each state, five major steps were taken:

1. Collection of existing local price indexes from all sources known
2. Adjustment of price series compiled by the National Industrial

PER CAPITA REAL INCOME CHANGE

- Conference Board to establish closer comparability with BLS series
3. Estimation of indexes for all items, based on existing local food price indexes
 4. Combination of available index series (including adjusted and estimated indexes) to state average indexes for the years for which any information is available
 5. Estimation of state indexes for other years, by imputation from price movements for nearby states

Sources of Price Index Series. The availability of local price indexes varies considerably from state to state. No indexes could be discovered for Nevada or Vermont; and only unpublished BLS price data, covering a two-year period, are available for one city each in North Dakota, Idaho, and Wyoming. On the other hand, state indexes for the total period 1929-1954 are available for Pennsylvania and Massachusetts, and a considerable number of city indexes are available for Ohio, California, and a few other states.

The major source of price indexes is the BLS. In all, some price information was available to the authors from this source for 112 localities in 125 index series. The NICB provided price series for 65 places, for 39 of which BLS series are also available for some periods. State agencies and universities contributed price series for 7 states and 32 localities, 8 of which are covered by the BLS and the NICB to some degree. Price indexes covering the entire period 1929-1954 are available for 25 cities located in 19 states and the District of Columbia. Indexes for 7 more cities are available for the period 1929-1952, and these add 3 states to the list for which price information has been recorded over an extended period.

Only 4 local agencies (3 state departments of labor and 1 university) are currently engaged in the calculation of indexes for all consumer prices. Three universities and 1 state department of labor calculate indexes of change in retail food prices. All-items indexes are calculated for the states of Massachusetts, New Jersey, and Pennsylvania. Indexes are also calculated for 3 cities in Pennsylvania and 6 cities in Louisiana. Retail food price indexes are calculated for the states of Kansas and Montana, and for Miami, Florida and Albuquerque, New Mexico, and 10 cities in Pennsylvania. Fuel price indexes are also calculated for the 10 Pennsylvania cities.

Other agencies which previously calculated consumer price indexes include the departments of labor in Michigan and Utah, and the University of Toledo.

The BLS is currently publishing price indexes for 20 large cities. Price information has been collected since 1952 for 26 additional

PER CAPITA REAL INCOME CHANGE

small cities, but the amount of data obtained is considered insufficient for the calculation and publication of index numbers for these places. The NICB calculates and publishes price indexes currently for 40 cities.

Table A-1 (in the appendix) lists the 229 price series for 162 cities and 7 states available for use in estimating state indexes, and gives the sources of these data.

Adjustment of NICB Indexes. Index methodology employed by the BLS, the NICB, and local agencies in the calculation of price indexes is basically the same. Most indexes produced by local agencies correspond very closely with BLS series in their composition and construction, and they were used without adjustment in the development of estimated state indexes. However, because of differences in methods of price collection and the lists of items priced, indexes compiled by the BLS and the NICB are not entirely comparable. Where indexes were available from both sources for the same city and periods, the BLS data were used in the state estimates. Available indexes compiled by the NICB, which were the only source of data for a city, were included in the state estimates after adjustment.

For the period 1939–1952, index series for the same twenty-six cities were compiled by both the NICB and the BLS. Comparison of these series on a 1947–1949 = 100 base shows that in general the NICB indexes are higher from 1939 through 1947 and lower from 1948 through 1952, increasing less than the BLS indexes over the period. A comparison of the two indexes (Table 2) for all cities combined describes this general pattern and suggests that ratio adjustments to the NICB series might bring them into close correspondence with the BLS indexes.

In testing this possibility, it was found that ratio comparisons for the twenty-six individual cities varied significantly from city to city, so that the use of an average ratio to adjust all the NICB indexes introduced substantial error in the resulting series. Differences in the index series of the two agencies for cities within the same region were very similar, however, and satisfactory results could be obtained through the use of ratios available for the nearest comparable city. All NICB data used in the state estimates were adjusted in this manner to correspond more closely with levels of the BLS series.

There is no doubt that better results could be obtained if adjustments were applied to the components of the NICB indexes. Major differences between the BLS and NICB indexes lie in the measurement of change in prices of clothing, house-furnishings, and miscel-

PER CAPITA REAL INCOME CHANGE

1948	102.5	102.8	1.003
1949	101.1	101.8	1.007
1950	102.4	102.8	1.004
1951	110.4	111.0	1.005
1952	113.2	113.5	1.003

laneous goods and services, and some investigation has been made into the reasons for these differences.² Given time, a more sophisticated methodology for adjustment could be based on this knowledge.

Estimates of All-Items Indexes Based on Food Price Series. For twenty-six localities, only food price indexes are available for some periods, and for ten cities both food and fuel indexes are calculated. These are valuable data, since there is a consistent relationship between the movement of food prices and prices of all goods and services other than foods combined, over the 1929-1953 period. On a 1947-1949 = 100 base, the United States food index was lower than the all-items index from 1929 to 1946, and moved around the all-items index from 1946 to 1953. In general, food prices were more volatile than those for other items over the entire period, changing at a more rapid rate over cyclical periods. This general pattern was consistent from city to city, and city ratios of food indexes to all-items indexes corresponded closely with the ratio for the country as a whole.

For localities for which only food indexes were available, all-items indexes were estimated by weighting together the food index for the city and the index of all items less foods for the United States. A

² See, for example, Horace B. Horton and George K. Batt, "Report of Industrial Members of the President's Committee on the Cost of Living," *Report of the President's Committee on the Cost of Living*, Office of Economic Stabilization, 1945.

PER CAPITA REAL INCOME CHANGE

similar procedure using indexes for foods, rent, and fuels was employed by the BLS in estimating indexes for selected small cities in the war years 1940–1944. These estimated indexes were used in the present calculations. Tests of the procedure on cities for which both food and all-items indexes are available show a close correspondence between estimated and calculated indexes in almost every case.

Combination of Local Data to State Urban Averages. City indexes available for any period during the years 1929–1954 (either from the original source or as a result of the estimating procedures described above) were combined to estimate state urban indexes. For this purpose, weights derived from various family expenditure survey results and census population counts were utilized. For the years 1929–1939, weights were based on expenditure data from the 1934–1936 surveys of family expenditures,³ and population data from the 1930 census; for 1950–1954, expenditure data from the 1950 survey of consumer expenditures⁴ were used with 1950 census figures; and for 1940–1949 the expenditure weights were averages of the 1934–1936 and 1950 surveys (with more weight given to the earlier surveys) and population weights were based on the 1940 census. For BLS index cities, expenditure weights were already available in usable form. For other cities, expenditures were estimated on the basis of survey data for cities most comparable in size, location, and income level. City indexes were combined for whatever periods they were calculated. When a series was started or discontinued, the city weights were adjusted so that the state average was not affected by the change in the number of series used.

Some information covering the period 1929–1952 (when the BLS revised its list of cities) was available for 32 cities and 2 states. This included two or more locality indexes or the state average in each of 9 states located in 5 regions; and one locality index in each of 13 states and the District of Columbia, located in all 7 regions. Data for the entire period 1929–1954 were available for 8 cities in the Central region, 6 in the Middle East, 4 each in the Southeast and Far West, and only one city each in the Northwest, Southwest, and New England regions (for the states included in these regions, see Table A-2).

To round out estimates for all states for all years from 1929 to 1954, the movement of prices for missing periods was imputed from estimated state indexes for a nearby state in the region. For ex-

PER CAPITA REAL INCOME CHANGE

ample, estimated indexes for North Carolina for the years 1929-1940 and 1952-1954 reflect the movement of the Tennessee index; indexes for Mississippi for the same periods were imputed from Alabama. Indexes for Idaho, Nevada, North Dakota, Vermont, and Wyoming for the entire period 1929-1954 were borrowed from neighboring states.

PRICE INDEX FOR THE RURAL POPULATION

Sufficient published information was not available for estimating price change for the rural population by state or region. The PPF index is published for the total United States by the Agricultural Marketing Service of the Department of Agriculture, and no state or regional indexes are calculated. Comparable series, compiled by state agencies in the Agricultural Estimates Organization are available for Maryland, Montana, and Wisconsin, and some work on PPF indexes has been done for Iowa, South Dakota, and Idaho.

In the course of compiling the United States PPF series, the Department of Agriculture calculates average prices by state and region for most commodities included in the index. Since about 1935, some average prices for selected food items have been published in issues of *Agricultural Prices*, and since 1948, publication of state average prices for selected foods and clothing has become a fairly regular feature of the price bulletin. However, chiefly because expenditure data for weighting purposes are not available, no attempt is made by the Department to combine state or regional data.⁵

The PPF index is not a complete index in that it does not include rents and other housing costs (other than building materials for houses) and it does not include medical care, personal care, and other services.⁶ Also, it is a farm series and does not pretend to represent the price experience of the rural nonfarm population. Even in the event that a regional breakdown of the index were available, adjustments would be necessary to include these missing elements in the development of an estimated index for the total rural sector.

For the purposes of this paper, the only estimate that could be made with the data at hand was one for the total rural population

⁵ The Agricultural Marketing Service agreed to make price data available to the authors for use in this paper. But lack of appropriate weights, and time to carry out necessary calculations with estimated weights, dictated against an attempt to develop state rural indexes at this time.

⁶ See Dorothy S. Brady and Roger F. Hale, "Comparison of Changes in the BLS Cost-of-Living Index and BAE Index of Prices Paid by Farmers for Commodities Used in Family Living," *Report of the President's Committee on the Cost of Living*, Office of Economic Stabilization, 1945.

PER CAPITA REAL INCOME CHANGE

for the years 1929–1953.⁷ This was done by combining the food, clothing, and house-furnishings components of the PPF series with the housing, fuels, and miscellaneous services groups of the CPI. Expenditure weights for combining these components were developed for the years 1929–1941 by combining the rural farm and nonfarm expenditure patterns obtained in the expenditure surveys of 1935–1936⁸ and 1941.⁹ The other sets of weight factors, one for the years 1942–1946 and one for the years 1947–1953, were based on adjustments to the survey data suggested by trends of farm family spending patterns developed by the (then) Bureau of Human Nutrition and Home Economics for the Agricultural Outlook Conference of 1953.¹⁰ In selecting the three components of the farm series, the assumption is made that prices obtained by the Department of Agriculture for these goods are typical of prices paid by the total rural population. For the other groups, the BLS and NICB data are the only available. The BLS indexes were used, in line with the choice of BLS over NICB data in the development of state urban series discussed earlier.

Over the entire period 1929–1953 the farm price series increased 76 per cent while the BLS urban index rose 56 per cent (Table 3).

TABLE 3

Percentage Change in Urban, Rural, and Farm Prices, 1929–1953

Period	Urban Prices ^a	Prices Paid by Farmers ^b	Estimated Rural Prices
1929–1933	–25	–30	–24
1933–1940	+ 8	+14	+ 7
1940–1945	+28	+50	+41
1945–1953	+49	+48	+44
1929–1953	+56	+76	+66

^a Bureau of Labor Statistics, CPI.

^b Dept. of Agriculture.

⁷ In an effort to obtain regional indexes for the rural population, an attempt was made to develop series from 1929 to 1953 for three regions. Food and clothing prices, published in *Agricultural Price* bulletins, were combined for the years 1943–1953 to estimate price movements for these groups. All other price data were based on the combination of available BLS group indexes for small cities in these regions. The results resembled the estimated rural price index used in this paper, and showed expected regional variations to some degree. However, there was no basis for judging these results or evaluating their accuracy with any degree of confidence.

⁸ *Family Expenditures in the United States*, National Resources Planning Board, June 1941.

⁹ *Family Spending and Saving in Wartime*, Bureau of Labor Statistics, Bull. 822, 1945.

¹⁰ *Rural Family Living*, Dept. of Agriculture, Bureau of Human Nutrition and Home Economics, October 1952.

PER CAPITA REAL INCOME CHANGE

Much of this difference could be attributed to the absence of services in the farm series during the war years, when commodity prices increased at a much more rapid rate than did service prices. During other years within the period, the two series moved within a relatively narrow band. The estimated rural index for all goods and services increased 66 per cent over the twenty-five-year period, reflecting the slower rate of change in rents and services while showing also the influence of the higher relative importance given to the three major groups of farm prices.

ESTIMATED STATE INDEXES

The authors' decision to use the estimated rural index in the development of total state index series for each state was based on two considerations: (1) the movement of prices in rural and urban communities differed significantly, chiefly during the war period, and both movements should be reflected in proportion to their importance in state totals; and (2) the estimated rural series was the best estimate for every state that could be produced at this time, short of a major calculation project.¹¹

¹¹ Prices paid by farmers for ten clothing items for the years 1943-1953, published in *Agricultural Prices*, were combined by census region to study interregional differences in price movement for this group. Estimated average price increases over the eleven-year period ranged from 64 per cent in the middle Atlantic region to 79 per cent in the mountain region, and in all other regions prices increased from 68 to 73 per cent. Percentage price changes for these ten items over shorter periods between 1943 and 1953 also showed significant differences:

	1943-1945	1945-1950	1950-1953	1943-1953
Rural farm (clothing prices paid by farmers, ten items):				
New England	13	41	8	72

Los Angeles, Calif.	9	28	5	48

(continued on next page)

PER CAPITA REAL INCOME CHANGE

The rural index was therefore combined with each estimated state urban index to derive total indexes by state. Weights used for this purpose (for the periods 1929–1939, 1940–1949, and 1950–1953) were developed from expenditure survey data and census population counts. The urban weights were based on expenditure data for all cities for which index series were available for any period during the years 1929–1953. As in the derivation of weights for combining city index series, survey data from the studies of 1934–1936 and 1950 were used with appropriate population data. Estimated average urban expenditures for each state were calculated by combining all available city expenditures with population weights. The resulting averages were weighted by the total urban population in the state.

Rural weights for the years 1929–1939 were derived from the 1935–1936 study of consumer purchases.¹² Average expenditures of farm families in twenty states were used to estimate expenditures for all other states. Survey data for later years were used for the few states for which they are available. For most states, weights for 1940 forward were based on the 1935–1936 aggregate expenditures adjusted to 1940 and 1950 by changes in aggregate farm income, as estimated by the Department of Commerce.

The United States urban and rural weights, combining population counts and expenditure levels, were distributed as follows:

<i>Period Used</i>	<i>Urban</i>	<i>Rural</i>
1929–1939	71.0	29.0
1940–1949	86.7	13.3
1950–1953	84.4	15.6

United States:

Clothing prices paid by farmers, ten items	18	33	7	68
PPF index (clothing)	21	31	7	71
CPI (clothing)	13	29	7	55

It is apparent from these calculations that there was a significant difference in the movement of rural and urban prices for clothing over this period. It seems apparent also that interregional variation in rural price changes and intercity variations in changes in urban prices are significantly different from the variance between total urban and total rural price change. It is assumed, therefore, that the average change in prices paid by farmers is a better estimate for any region or state than an estimate based on urban prices within the region.

Comparable calculations, using published food prices paid by farmers over a shorter period, lead to the same conclusion, although a sufficient number of prices were not available for food items to develop satisfactory indexes.

¹² *Family Income and Expenditures, Farm Series*, Dept. of Agriculture, Misc. Pub. 465, 1941.

PER CAPITA REAL INCOME CHANGE

EVALUATION OF RESULTS

The state price indexes presented in Table A-2 for the years 1929-1953 were developed from published index series, except for the use of unpublished indexes for twenty-six small cities (for the last two years) which were estimated from BLS records. In all, some index data, published by the BLS, the NICB, or state agencies and universities, were available for 162 separate urban places. The number of cities covered by these indexes varied considerably from year to year. For the war period 1940-1945, which was covered most adequately, 178 indexes for large and small cities (including duplications) were available, while for the years 1929-1935, the only city indexes on record are those produced by the BLS for thirty-two large cities. Only the national index and a few state indexes of prices paid by farmers were available for the rural farm population, and no price information was found specifically for the rural nonfarm sector.

Published urban price indexes, of course, represent only the change in prices paid by urban wage-earner and clerical-worker families. They were used throughout this study to represent price change for the total urban population. There is no satisfactory evidence available that would indicate whether any adjustment for this deficiency is necessary or what direction such adjustment would take if warranted.¹³

These state indexes, therefore, are composites of this varying amount of partial information about the average movement of prices for all goods and services combined, weighted together to reflect average change in prices by state and region. They are offered as the result of a gross estimating procedure which used available price index data known to the authors, and they are conditioned by judgment decision on the part of the authors in the development of weights and imputation patterns. Although their main purpose is to reflect interstate differences in the movement of prices, to some extent differentials in price change from state to state have been dampened by the choice of methodology. For example, the estimated United States average movement of prices paid by the rural population is reflected in each state index, although interstate

¹³ Simple reweighting of group, subgroup, or even item price change computed for a wage-earner and clerical-worker family index does not provide sufficient evidence of probable differences in the average change in prices experienced by other groups of the population. In addition to expenditure weight patterns for single consumers, families at the extremes of the income range, and other population groups, the calculation of component indexes for the total population would require the measurement of price changes for the different kinds and qualities of goods and services used by the population subgroups.

PER CAPITA REAL INCOME CHANGE

differences in price changes in rural areas may be very significant.

The methodology followed in the development of these series ignores most of the technical and theoretical considerations that have been discussed by students of the deflation process.¹⁴ The estimates go directly to the total and do not provide the component index series required for deflation of components of income which represent varying proportions of the total over time. No consideration was given to the inherent deficiencies in the published price indexes as valid deflators of income data, e.g. quality changes and the differential movement of prices for goods at different quality levels. No attempt was made to introduce adjustment to the BLS indexes for the understatement of price change during the war period, estimated by the President's Committee on the Cost of Living and the Stabilization Director to be about 5 index points on the national index. It may well be that refinement of the process would not substantially change the results of deflation, but there is no statistical evidence to support such a conjecture.

The weighted average of the state price indexes differs substantially from the Department of Commerce implicit price deflator for personal consumption expenditures. Reasons for these differences have not been investigated.

A general conclusion may be drawn upon inspection of the state price indexes that as the result of basic economic factors operating nationwide, there has been a remarkably close correspondence between regional and state price movement over the period studied, and that this was probably more true in the prewar rather than post-war years. State indexes measure the average movement of prices in large geographic and population areas within which significant differential changes in locality prices were taking place. The same factors causing variations in price change, although they cannot be clearly identified, are most probably present in each area, though perhaps not in the same proportions. In the aggregation of differential price movements over large state areas, variations are smoothed over and only the differential effects and values of the factors operating in each area are revealed in the average. One might expect, therefore, that interstate variations in price changes will be much less pronounced than differences observed in locality data.

On the other hand, there is a large degree of correspondence between the dispersion of price change reflected by the state indexes and the amount of price index information that went into their construction. Estimated price decreases from 1929 to 1933, by state,

¹⁴ See, for example, John H. Smith, *Statistical Deflation in the Analysis of Economic Series*, University of Chicago Press, 1941.

PER CAPITA REAL INCOME CHANGE

ranged from 18 to 30 per cent; but thirty-nine out of the forty-nine indexes measured a change of from 23 to 25 per cent. This was the period for which the least amount of price information was available. Over the war period 1940–1945, for which many more price series were calculated, estimated increases in state average prices ranged from 26 to 37 per cent, and only twenty states fell in the modal range of 31 to 33 per cent increase. The one chief feature of these state indexes may well be the extensive possibilities that exist for their improvement and the effort that their publication may stimulate toward this improvement. The indexes are in no sense presented as a final product. Many sources of unprocessed price data, and perhaps calculated price index series not known to the authors,¹⁵ might fill in some of the temporal and spatial gaps in the information used for the 1929–1953 period, and an intense review and reprocessing of existing family expenditure data might well provide a more satisfactory system of weights.

More important, however, are the possibilities for future years. The BLS and other governmental agencies have long recognized the great need for expansion in local price program coverage and for more frequent studies of consumer expenditure patterns. The Bureau's plans of years past, which are still in the realm of fancy and hope, called for price indexes for one hundred or more cities, and continuing expenditure surveys in three or more cities a year. These plans were not entirely visionary. They originated through awareness of a growing need for more local price statistics and were thwarted only because sufficient funds were not forthcoming. It is not unreasonable to look forward in the near future to the existence of continuing price studies for perhaps hundreds of localities. A great advance in this direction will be made, perhaps without additional funds, by improved efficiency in price collection and index calculation techniques now contemplated by the BLS and by closer cooperation and elimination of duplicating efforts on the part of other index makers.

In this attempt to develop state price indexes for the period 1929–1953, the major areas for which lack of data handicapped the work were, in order of their importance:

1. State or regional price data for rural farm and nonfarm communities over the entire period
2. Urban price data for states in the western regions over the entire period

¹⁵ The authors will appreciate receiving knowledge of price series not included in this report and suggestions that can be used to improve the estimates.

PER CAPITA REAL INCOME CHANGE

3. Price series for the 1929-1935 period for small cities
4. Expenditure weights for rural farm and nonfarm families in the war and postwar years
5. Information about causal relationships between price change and economic and demographic characteristics of communities
6. Information about the price experience of urban populations other than wage-earner and clerical-worker families

The dearth of necessary information for some regions and time periods places serious limitations on the validity of the state estimates to discriminate differentials in price change with the same degree of confidence for every state. As a guide in the use of the state indexes, the authors offer their evaluation of the reliability of the figures. Table A-3 presents a relative quality-rating diagram based on the amount of necessary price and weight information that was used to represent the total state population. In tabular presentation of the results, calculated indexes have been rounded to whole numbers in recognition of the lack of their significance to more places.

There is no doubt that the accuracy of the results could be improved if additional sources of data are discovered. However, except for greater use of available rural data, there is little chance that these gaps can be filled easily. We can hope only that a more intensive search will reveal some price information for this period not now known generally to exist, and for better estimating techniques using increased knowledge of price relationships for current periods. Rural prices for commodities bought by farmers are available in the records of the Department of Agriculture. These data could be combined with estimates of change in prices paid for services, to develop regional price series for the rural population for prewar years (for which some expenditure-weight data are available for scattered surveys). For war and postwar periods, the absence of rural expenditure patterns presents a difficult estimating problem.

Estimates of state urban price indexes presented in Table A-4 are somewhat more indicative of interstate differentials in price changes than are the index numbers for urban and rural combined, which reflect only the estimated national average movement of rural prices. However, for use as deflators of state income payments, the estimated state price indexes are perhaps most appropriate, since they include, in addition to urban price data, an estimate of the differential movement in commodity prices paid by the rural community (as measured by the PPF index). Since rural prices of commodities

PER CAPITA REAL INCOME CHANGE

used in family living advanced more than urban prices from the depression through the war years (see Chart 1 above), the inclusion of an estimate of their movement over the period covered introduces an adjustment to the level of the state indexes in the right direction at least.

Findings

The authors, having devoted all of their time to the calculations, must leave it to others to discover whether the state price indexes will contribute anything to the large body of knowledge already at hand or assist in explaining regional differentials in income payments. A measure of the value of these calculations will be the degree to which they are used successfully (until better figures are produced) as an additional factor in the analysis of income trends and variations. Evaluation of the results can be provided only through attempts to fit the data into the gap that has handicapped some researchers in their studies of income and other related economic factors. The following description is drawn simply from the tabular data.

REGIONAL VARIATIONS IN PRICE CHANGE

The cyclical peaks and troughs in the movement of prices over the 1929–1953 period occurred in the same year in every state. The low point of the Great Depression was reached in 1933, followed by recovery to 1937. Prices fell in every state in the recession years 1938–1939 and again in 1949. On the average, prices fell about 6 per cent per year between 1929 and 1933; increased a little more than 1 per cent per year to 1940, over 6 per cent per year from 1940 to 1945, and almost 6 per cent per year in the postwar period to 1953. The greatest rate of change occurred between 1945 and 1948, when prices advanced 36 per cent, or 12 per cent per year.

Variations in price change from state to state formed a pattern associated with these general shifts in rates of price movement. In periods of rapid change in prices, interstate variance in price change increased; in periods during which price changes were relatively smaller, the variation in price change between states narrowed. Annual changes in state price indexes from 1930 to 1934 varied within a range of from 4 to 6 per cent, and from 1946 to 1948 they varied over a range of 5 to 6 per cent (Table 4). On the other hand, state price changes varied within 2 to 3 per cent from 1934 to 1940, 1942 to 1946, and 1951 to 1953.

The regional classification used by the Department of Commerce in presenting state income data and adopted for this paper does not

appear to be entirely appropriate to discriminate groups of states having similar price movement. In general, however, prices in the southeastern states decreased more than in most other states in the depression period, advanced more rapidly in the war years, and lagged behind in the general postwar price rise. The four far western states behaved more like a homogeneous group than did states in other regions and showed a distinct difference in price movement in many years. In 1934, 1942, 1947, 1948, and 1951, years in which the dispersion in price change among the states was high, far western states were among those showing either the highest or lowest price change from the preceding year. From year to year the District of Columbia was almost consistently among states registering the smallest annual price change. Prices in the New England states dropped less than the average in the depression years and advanced less than the average in the postwar period, but made the sharpest advance of all average regional price increases in the recovery period

PER CAPITA REAL INCOME CHANGE

1933-1937. Other regional patterns, not so obvious as these, are discernible in the figures in Table A-5, which show state and regional price changes from the previous year, and Table A-6, which presents price changes over cyclical periods. State variations in price change are shown in Table 5.

Source: Based on Table A-6.

Over the entire period 1929-1953, prices in the United States advanced about 57 per cent. Regional price change over this twenty-five year period ranged from 62 and 61 per cent in the Far West and Northwest to 55 and 54 per cent in New England and the Middle East. The greatest over-all price increases occurred in six states in the Northwest and Far West, and in Maryland (65 per cent or more); in the remaining states in the Northwest and Far West, price increases ranged between 60 and 64 per cent. Increases in most of the New England and Middle Eastern states ranged from 52 to 56 per cent, but Delaware, Connecticut, New Hampshire, and the District of Columbia were up 60 to 63 per cent. In the Southeast, prices averaged from 56 to 62 per cent higher in 1953 than in 1929, while in the Southwest the price movement was in a slightly narrower range. Prices in all except one of the Central states rose between 56 and 60 per cent during the twenty-five-year period.

RELATIONSHIP BETWEEN PRICE AND INCOME CHANGE

The movement of prices over cyclical periods between 1929 and 1953 differed from changes in per capita income in two major respects: (1) the rates of change (and therefore the amplitudes of cycles) were much lower, except over the postwar price inflation period 1945-1948; and (2) at the turns, prices tended to lag behind income.

There was no time in the preparation of this paper to test for correlation between state price and per capita income changes. Exam-

PER CAPITA REAL INCOME CHANGE

ination of Table A-5, which shows annual percentage changes in both series, suggests that coefficients of correlation would vary considerably depending on the time periods selected for measurement and would show some regional variation in the amount of correlation between price and income change in the selected periods.

Lag in the movement of prices behind per capita income is, of course, observable in the average United States price and income series. This was general nationwide and is more apparent in the state data. From 1932 to 1933, when the average change in both series was down, per capita income decreased relatively little in most states and increased in fourteen States, while prices continued to fall in all states. In the recession of 1938-1939, in every state prices continued down in 1939 while per capita income increased after substantial drops in 1938. And into 1940, prices remained relatively constant while the rate of increase in per capita income accelerated.

At the end of the war in 1945 and 1946, per capita income leveled off generally and decreased in many states, while prices continued up at an increasing rate. In 1949, both series turned down, except for scattered continued advances in per capita income in some states. In the following pre-Korean-War year, small price increases were associated with rather sharp advances in per capita income. In 1953, when the current period of relative stability in prices began, no clear pattern of relationship between price and income change was apparent. In eleven scattered states, mostly in the Northwest, where per capita incomes were lower than in the preceding year, prices continued to increase at a slow rate. On the other hand, in three New England states showing constant or falling prices, per capita income increased.

REGIONAL DIFFERENTIALS IN "REAL" PER CAPITA INCOME CHANGE

Table A-7 presents state and regional per capita income payments from 1929 to 1953 deflated by the estimated price indexes calculated for this paper, and Table A-8 presents these data in index form on a 1929 = 100 base. Chart 2 compares the movement of prices and per capita income in current and 1947-1949 dollars from 1929 to 1953 for selected states.

In terms of 1947-1949 dollars, average United States per capita income advanced 60 per cent from 1929 to 1953, compared with an increase of 151 per cent in the current dollar per capita figures. Real gains in income of 111 per cent and 94 per cent in the Southeast and Southwest, respectively, were more than double comparable

PER CAPITA REAL INCOME CHANGE

advances of about 40 per cent in New England, the Middle East and the Far West, and one-third and one-half more than the increases of 78 and 65 per cent in the northwestern and central regions. The greatest gain in purchasing power of per capita income was registered in South Carolina, which had the lowest per capita income of all states in 1929. There is a high correlation over all forty-eight states and the District of Columbia between increases in the real income series from 1929 to 1953 and the level of per capita income in 1947-1949 dollars at the beginning of the period. Within this relationship, New York and the District of Columbia, starting at the highest levels of per capita income, registered the smallest advances, the District of Columbia gaining only 8 per cent over the entire period.

From 1929 to 1933, real income fell more in the northwestern and central regions than in other sections of the country, while New England and some of the southeastern states were least affected by the depression. By 1940, all but a few states had regained their losses in buying power of per capita income. Recovery came quickest in the Southeast, where by 1936, most states had advanced above their 1929 level. However, from the depression through the prewar years, greatest gains were made in northwestern and central states. In the war years 1940-1945, the southern and northwestern states won the greater part of their twenty-five-year improvement with per capita income in 1947-1949 dollars increasing over 85 per cent in these regions. This compared with an average increase of only 40 per cent in New England states. The District of Columbia shared none of these wartime gains in purchasing power, which ranged from 21 per cent in Delaware to 114 per cent in South Dakota. States having the highest advance in real per capita income also experienced the highest increase in prices during this period.

From 1945 to 1950, the rise in prices exceeded or equaled increases in per capita income in every state except Delaware and the District of Columbia, the only places where postwar gains in real per capita income were achieved. In New Mexico price increases canceled out the total gain in per capita income in this period, and in other states real per capita income decreased from 2 to 16 per cent. These measurements veil the greater decreases that accompanied the recession of 1949. In the post-Korean-War period, real per capita income continued to fall in several northwestern states, resulting in an increase of less than 3 per cent in the West, while other sections of the country advanced toward or exceeded their wartime peaks. The District of Columbia suffered a substantial loss

CHART 2
Income and Price Indexes, United States and Selected States,
1929-1953

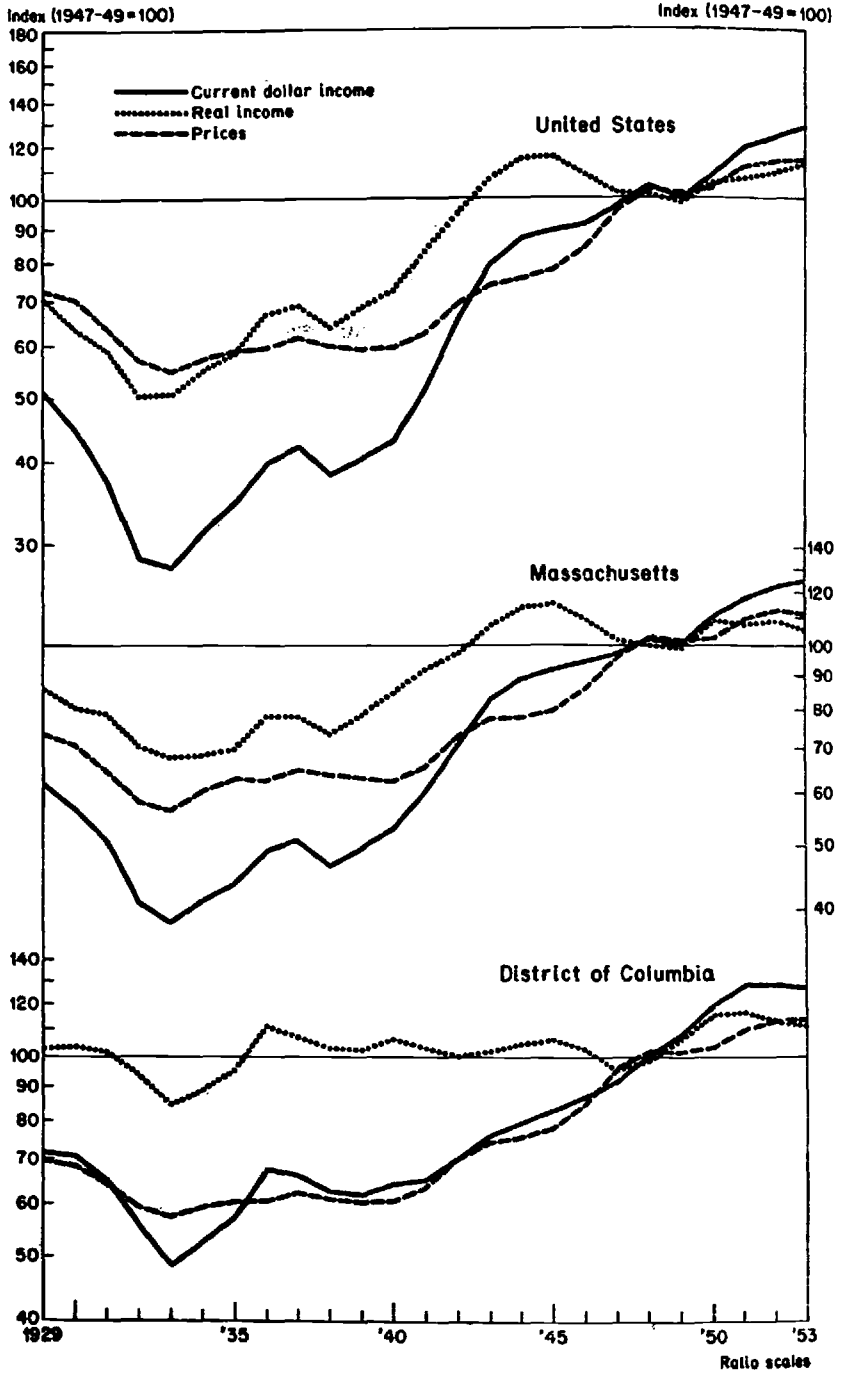

CHART 2 (continued)

in real per capita income from 1951 to 1953 and ended up no better off than it was in 1936.

CHANGE IN RELATIVE POSITION OF STATES TO THE NATIONAL AVERAGE

Availability of the deflated state per capita income series does not add materially to knowledge about the relative per capita income position of the states to the national average, which has already been subjected to some investigation.¹⁶ Variations in price change between states were not of sufficient magnitude to shift the position of most states from their relative levels in terms of current dollar per capita income, which changed so dramatically over the twenty-five-year period. Only in a few cases were percentage changes in relative position of the states from 1929 to 1953 significantly different from those calculated with current dollar figures. In 1953, Delaware, Connecticut, New York, Nevada, and the District of Columbia, in that order, held the top per capita real income position relative to

¹⁶ See, for example, Charles F. Schwartz, "Regional Trends in Income Payments," *Survey of Current Business*, September 1948.

PER CAPITA REAL INCOME CHANGE

the national average. Mississippi, Arkansas, Alabama, and the Carolinas were at the bottom of the array. In terms of 1947-1949 dollars, the dispersion of relative per capita income positions had narrowed considerably over the twenty-five years, shifting from a range of from 182 per cent for the District of Columbia and 41 per cent for Mississippi in 1929 to a range of 137 to 49 per cent in 1953. The District of Columbia experienced the greatest downward change (-32 per cent) in relative position, while South Carolina's relative position to the national average improved 74 per cent. In the twenty-five years Mississippi, while improving its place relative to the average, never relinquished its lowly rank among the states.

Table A-9 presents state and regional indexes of per capita income in 1947-1949 dollars, based on the United States as 100; and Table A-10 shows the average change in these state relative positions from 1929 to 1953. These indexes, of course, must be used with awareness that the income figures on which they are based have not been adjusted for variations in the level of prices from state to state. Although some adjustment could be attempted, based on existing studies of intercity differences in price level, only the roughest approximations to true differentials in real income could be expected.

Relative cost of living indexes for fifty-nine cities at March 1935 prices, published by the Works Progress Administration,¹⁷ indicate that a fair correlation existed between relative price levels and the per capita income position of states. It can be anticipated, therefore, that adjustments to state per capita income for differences in price level would tend to reduce interregional differentials further. Taking the WPA indexes for Washington, D. C.; Philadelphia, Pittsburgh, and Scranton to represent Pennsylvania; Memphis and Knoxville to represent Tennessee; Los Angeles and San Francisco to represent California; and Mobile and Birmingham for Alabama; the following comparison was made of 1935 per capita income in current dollars and adjusted for price change and level differences:

State	In Current Dollars	Adjusted for Price Change to 1947-1949 Dollars	Adjusted for Vari- ation in Price Level from U.S. Average
District of Columbia	955	1,581	1,409
California	617	1,055	990
Pennsylvania	510	881	854
Tennessee	260	455	476
Alabama	213	371	403
Alabama (D.C. = 100)	22.3	23.5	28.6

¹⁷ Margaret L. Stecker, *Intercity Differences in Costs of Living, March 1935, 59 Cities*, Works Progress Administration, Division of Social Research, 1937.

PER CAPITA REAL INCOME CHANGE

CONCLUSIONS

Only after the attempt is made to develop state and regional price indexes for past years can one conclude that an attempt would be somewhat foolhardy. The neglect of wide areas in past programs of price and expenditure data collection and processing has resulted in serious gaps in the body of statistical data necessary for these measurements. Therefore, only rough estimates of differentials in price movements can be obtained and no satisfactory adjustment for differences in price level can be made for years already past.

The inventory of available price data highlights the course taken in the progress of price studies to date. Major activity in this field has been directed toward solving practical and usually urgent problems; problems of the wage earner in war industry centers, problems of protective tariffs, problems of price control and farm parity legislation, problems of validating the use of one price series to impute movements to many unknown areas—large cities to small cities, for example—and now, problems of the low-income groups and the aged. Very little has been done in the nature of pure research into price statistics without any other motive than perhaps to make possible ready answers to many urgent problems before they arise.

It can be readily demonstrated that the amount of price information going into the creation of modern price series is in excess of the quantity of observations required. Valid and reliable estimates of price change can be compiled using smaller probability samples of items and reporters. A movement in this direction, accompanied by continued improved efficiency in methods of data collection and processing, would free funds and energy for much-needed price work in uncovered areas and would permit the collection of a large body of local price information for a variety of analytical studies. Expanded price research in the future would help fill the gaps in historical records by providing the knowledge about price relationships needed for design of better estimating techniques.

C O M M E N T

NATHAN M. KOFFSKY, Agricultural Marketing Service,
Department of Agriculture

Abner Hurwitz and Carlyle P. Stallings have my respect for undertaking the considerable job of assembling all the information available to them on consumer price trends, of developing price indexes for each state and region for the period since 1929, of presenting tabulations of per capita real income trends for the twenty-five-year period every which way, of inventorying the major gaps in price data; and, as a final tribute to thoroughness and persistence, of preparing an evaluation of the quality of their price indexes. Furthermore, they have anticipated most of the possible criticisms of their work.

They have my sympathy for the somewhat negative results of their research. As they indicate on page 217, they have found little variation in price trends among the states and regions. This does not imply that they have been wasting their time. If it can be assumed that consumer price trends are much the same over time throughout the nation, the task of analyzing income trends is simplified. Is such an assumption justified?

If 1953 is compared with 1929, the regional consumer price indexes developed by Hurwitz and Stallings show a spread in regional

PER CAPITA REAL INCOME CHANGE

price trends of from 2 per cent below to 2.5 per cent above the United States average. This variation is small, if not insignificant, compared with the rise of almost 60 per cent in average consumer prices during the twenty-four years.

Do the price indexes adequately reflect regional variations in price trends? I am not questioning what the authors have done to the urban indexes; they had a considerable body of price data and experience to work with. But they admit that the weakest part of their calculations is their treatment of the rural price index.

Hurwitz and Stallings have developed a rural price index for the United States (covering the rural nonfarm people as well as farm people) by combining the food, clothing, and house-furnishings components of the United States prices paid by farmers index published by the Department of Agriculture with the housing, fuels, and miscellaneous services groups of the Bureau of Labor Statistics consumer price index. This is a compromise to allow for the omission of service rates from the PPF series and to give weight to the combined living expenditure pattern of rural farm and nonfarm people. In general, the authors were explicit in explaining what they did. In this crucial step also they should have shown in detail how they obtained the combined rural expenditure weights, especially those assigned to housing and food. Based on what I think they did, I question applying urban housing trends to farm families or even to rural nonfarm families. I might also have tried to make allowance for the fact that a substantial part of the farm income is from farm-produced food.

The second critical choice was to use the United States rural price index for each state in the absence of sufficient price data to construct individual state indexes. This is not a reasonable way of determining regional and state variations in price trends. Would relying entirely on urban price trends have made much difference? Urban regional price trends are very much like the total regional trends. This is not unexpected, because urban price trends for the United States for some components were used in the rural index, and the trends in urban regional indexes were all much the same. Perhaps it would have been better to apply United States weights to the regional and state prices paid by farmers for food and clothing for the available periods to determine what variation existed in these components.

Would rural indexes that adequately reflect price trends in each of the several regions give significant differences in interregional variation? An index of prices paid by farmers for living items published recently by Montana for the period 1935-1953 shows that,

PER CAPITA REAL INCOME CHANGE

compared with 1929, Montana prices rose some 11 per cent less than United States prices. But in Montana, the postwar pattern of purchases was priced in the index, while the index for the United States represents prewar patterns. The difference between the two indexes may reflect largely the diverging biases of the Laspeyre and Paasche index methods over time.

Although urban price trends are weak for the early years, they have a much better base for acceptance than rural trends. Yet they show little interregional difference. Even where the rise in real incomes per capita has been greatest—in the Southeast, Southwest, and Northwest—price trends have not differed significantly from those in regions where income growth has been much slower. Should we expect that regional rural indexes, if they were available, would show something else? This is a question that is not likely to be answered from materials presently available. But if differences do exist in regional price trends, they appear more likely to rise out of population shifts from the country to the city than from different regional movements of either urban or rural consumer prices.

I believe that effort would better be directed, once again, toward developing a basis for comparing regional and state real incomes and toward determining the differences in purchasing power between, for example, the \$1,000 per capita income in the Southeast and the \$1,800 income in the middle eastern states. Such differences are also pertinent to comparisons of incomes of farm people with others. Some of the missing data listed by the authors may become available in the next year or so. The Department of Agriculture has made a survey of farm family expenditure patterns. When published, it will provide the first nationwide information on farm family expenditures in the postwar period and the survey was planned so that it would obtain enough information to indicate major regional differences in living patterns.

MARGARET G. REID, The University of Chicago

Abner Hurwitz and Carlyle P. Stallings had a difficult task. I agree with Nathan M. Koffsky that they have carried it out with great skill and ingenuity and have done an admirable job in describing their procedures. Apart from the price indexes of various cities included in the Bureau of Labor Statistics consumer price index, only fragmentary price information and scanty supplementary facts for the development of suitable weights were available. The list of various price series in Table A-1 will be useful to other workers in this field.

PER CAPITA REAL INCOME CHANGE

The authors devoted considerable space to the appraisal of the series, their coverage of populations in various states and of items in consumer budgets, and the adequacy of weight diagrams to represent current consumption. Perhaps more should have been said about differences among the indexes in the methods of price collection, especially as these bear on correlations between income and price change. Some comparisons were made between the clothing index of the CPI and the prices paid by farmers index. I wonder whether sufficient attention was given to the likelihood that the method of price collection used more by the Department of Agriculture than by the BLS reflects the varying quality of clothing purchased with higher and lower incomes to a greater extent than the CPI. The controversy in the early 1940's over the accuracy of the CPI index involved comparisons between the prices of the two indexes. At that time, Dorothy S. Brady and O. V. Wells made a detailed comparison of them to which it would seem worthwhile to refer.

Many people are going to be grateful for the state price indexes. Some will be glad for the reassurance that the CPI is a reasonably good index for various parts of the United States. This has long been the assumption, partly because of the lack of local indexes. Others will be glad to have a local index because those who turn to them for information on price trends, whether university administrators or local editors, are skeptical of the applicability of the general index.

The main findings of this paper, that differential price trends among the states for 1929 to 1953 were too small to affect trends in relative real income, lead me to question the authors' recommendations that increased effort should go to securing more local price indexes. I agree that more and better price series might demonstrate more differences than this paper shows. They might also demonstrate less. But the likelihood of any difference being found that will influence the conclusions as to trends in relative real incomes of states seems very small indeed. Of course, local price series may have other justifications.

This paper, like many others that explore a set of empirical relations, may have important by-products. In scanning the data in Table A-5 on percentage change in income compared to percentage change in price, I wondered about their contribution to our knowledge of their interrelation. It would be helpful to have price indexes of various components, e.g. food, rent, and clothing. There may well have been important differences among these. There are several reasons for such expectations, for example, (1) the pricing speci-

PER CAPITA REAL INCOME CHANGE

fications are such that the index for food more nearly than that for other products describes price changes of a given quality, whereas the specifications for clothing are broader, and in periods of income decline responses of retailers to lower local demand may well result in a reduction in the quality of clothing and (2) products differ in the extent to which they are part of a national market. Food and clothing of various local areas are mainly segments of a national market. Price changes of local areas will be unique only if the quality priced varies with income or if local wholesaler and retailer margins are affected. Rent, on the other hand, is largely determined by local demand, but it has contractual aspects that make it sticky.

In the piecemeal accumulation of knowledge, one addition leaves little room for complacency. Attention shifts to the unanswered questions. To return to the title of the paper, "Interregional Differentials in Per Capita Real Income Change," important price trends affecting these differentials have been occurring that were not taken into account by price indexes of the type described in this paper. The indexes relate to price change in various types of communities. They take no account of differences in prices paid because of the shift of population among communities. Population movement has reduced the percentage on farms, and the reduction has been greater in low income states than in high income ones. This shift has tended to increase the prices paid for a given bundle of commodities. The per capita dollar incomes of states show a greater relative increase during the 1940's in states in the South than in the United States as a whole. My guess is that this difference would be reduced if the effect of population shifts by type of community were taken into account. A paper by Koffsky on the relative cost of living of farm and nonfarm population provides some basis for estimating such effects.¹

Scholars investigating interregional differentials in income have two quite different problems: (1) the estimation of differences at a point in time and changes that have occurred, and (2) the determination of the character of forces effecting change. For the latter, economic theory provides the basic hypothesis. It postulates that resources tend to move to the location where returns tend to be maximized. It is my hunch that 1950 census of population and supplementary material from earlier censuses hold great potential for the study of population movements in search of the highest real

PER CAPITA REAL INCOME CHANGE

income. Cooperation is needed between population analysts and economists with a special interest in migration and income distribution. Even a superficial examination of the data in the 1950 census indicates that net migration is away from the low income states.
