Abstract:

We draw on knowledge spillover literature to suggest that a country's proportion of export-oriented new ventures, compared to its total number of new ventures, represents an *outcome* of knowledge spillovers (export spillovers) that stem from foreign direct investment (FDI) and international trade, as well as a *source* of knowledge spillovers (entrepreneurship spillovers) that positively influence the country's total level of entrepreneurial activity. We distinguish between higher-income and lower-income countries, because the latter are less integrated into the world economy. To test the hypotheses, we use macro-level data from 34 countries during the period 2002–2005. After controlling for relevant factors such as size of the domestic market and industry structure, we find that the relationship between FDI and international trade on the one hand and a country's proportion of export-oriented new ventures on the other differs for higher- and lower-income countries. In addition, a country's proportion of export-oriented new ventures affects the subsequent emergence of new businesses. These findings have important implications for research and practice.

Keywords: knowledge spillovers, export, country-level entrepreneurship, international new ventures

Version: 14 November 2007

INTRODUCTION

Evidence indicates that the number of international new ventures, that is, ventures that view their operating domain as international at or near their inception, is increasing in many countries around the world (Moen, 2002; Oviatt and McDougall, 1994; Rennie, 1993); in response, a wealth of research investigates factors that drive new venture internationalization (Autio et al., 2000; De Clercq et al., 2005; McDougall et al., 1994). Research on international new ventures mainly concentrates on exporting, a common entry mode that young entrepreneurial firms use to internationalize (e.g., Burpitt and Rondinelli, 2000; Campbell, 1996; Zahra et al., 1997), but knowledge about why some countries have more export-oriented new ventures than others and whether and how export-oriented new ventures contribute to macro-economic outcomes remains limited. We address such issues by investigating macro-level antecedents and outcomes of a country's proportion of export-oriented new ventures.¹ In particular, we argue that the proportion of export-oriented new ventures represents both an *outcome* and a *source* of knowledge spillovers. Furthermore, current understanding of international new ventures relies mainly on case studies or single country samples, despite the need to track and study international new ventures in multiple countries (Coviello and Jones, 2004; Oviatt and McDougall, 1997). Therefore, we consider 34 countries over a four-year period to uncover trends across different economies.

Entrepreneurship literature examining the early entry of new firms into foreign markets relates internationalization mainly to individual-level factors, such as entrepreneurs' international experience (Bloodgood et al., 1996; McDougall et al., 1994; Oviatt and McDougall, 1995), or firm-level factors, such as entrepreneurial orientation (Sapienza et al., 2005) or a technology or

¹ We focus precisely on the *proportion* of new ventures *relative* to the total number of new ventures that target at least 26% of customers in foreign countries (Moen, 2002). For parsimony, we use the shortened term "proportion of export-oriented new ventures" hereafter.

knowledge base (Autio et al., 2000; Keeble et al., 1998). Whereas this literature acknowledges the importance of macro-level environmental conditions (e.g., economic integration, transportation advances) to explain the emergence of international start-ups (Bloodgood et al., 1996; Knight and Cavusgil, 1996; Oviatt and McDougall, 1994; Rennie, 1993), empirical contributions generally fail to include macro-level factors as possible determinants of new ventures' international orientation. We argue that two important categories of macro-level factors may serve as determinants of new ventures' export orientation: foreign direct investment (FDI) and international trade. Recent research suggests that FDI and international trade offer likely sources of export spillovers (Aitken et al., 1997; Banga, 2003; Greenaway et al., 2004; Kneller and Pisu, 2007), which take place when knowledge about foreign markets or other knowledge that is useful for operating in foreign markets (e.g. technological knowledge) transfers from one economic actor to another or competition forces actors to become more productive through exporting (Kneller and Pisu, 2007). Building on the literature on export spillovers, we posit that a country's level of inward and outward FDI, export, and import positively relates to the share of new ventures that focus on serving customers abroad. Furthermore, we speculate that export spillover effects may depend on the country's capacity to absorb such spillovers (Borensztein et al., 1998; Durham, 2004; Görg and Greenaway, 2004; Gugler and Brunner, 2007) and, more specifically, that higher-income countries may benefit more from such spillovers than their lower-income counterparts.

In addition to studying macro-level antecedents of new ventures' export orientations, we examine a possible consequence of such export orientations, namely, an increase in the number of new businesses. Few empirical studies focus on the possible economic contributions of international new ventures. Some investigate the impact of early internationalization on growth

and profitability (Autio et al., 2000; Bloodgood et al., 1996; McDougall and Oviatt, 1996; Zahra et al., 2000) but typically at the firm level. We instead argue that export-oriented new ventures within a country may generate spillovers that encourage the set up of (more) new businesses within the country's borders (entrepreneurship spillovers). We suspect that export-driven new ventures may be an important *source* of knowledge spillovers, because such ventures tend to be innovative and have high human capital levels (Bloodgood et al., 1996), and thus serve as role models for aspiring entrepreneurs (Davidsson and Honig, 2003). Thus, we add to literature that suggests that the nature of early-stage activity may provide an important source of spillovers (Audretsch and Keilbach, 2004; Parker, 2005).

The scope of this article encompasses whether we can identify a relationship at the *macro-level* (1) among inward FDI, outward FDI, and international trade on the one hand and the proportion of export-oriented new ventures on the other hand and, in turn, (2) between the proportion of export-oriented new ventures and a country's total level of entrepreneurial activity. Thus, though we draw from economics literature on knowledge spillovers to predict and interpret these macro-level relationships, we leave it for further research to investigate, at the *micro-level*, how such knowledge spillovers take place among individual economic actors.

THEORETICAL BACKGROUND

The term "spillover" pertains to the transfer of knowledge across economic players; such spillovers may enable important productivity gains (Coe and Helpman, 1995; Jaffe et al., 1993; Marshall, 1920). According to endogenous growth theory, a country's economic growth stems from the endogenous development of knowledge through spillover effects across economic actors (Romer, 1986). Spillovers or knowledge externalities allow firms to acquire knowledge from other economic players without having to pay for it in a formal market transaction (Acs et

al., 1994; Bernstein and Nadiri, 1988). They take place from one firm to another partially because knowledge represents a public good (Grossman and Helpman, 1991) or a “non-rival” asset that different economic actors may use simultaneously in different locations (Romer, 1990). Furthermore, knowledge generally is not excludable, so knowledge-generating firms have difficulty extracting compensation in return for others’ use of their knowledge (Grossman and Helpman, 1991). Thus, knowledge-generating firms cannot fully appropriate or internalize the returns on knowledge investments, and some returns spill over to benefit others as well.

Export spillover effects and new ventures’ export orientation

Many studies on knowledge spillovers focus on productivity spillovers (for an overview, see Görg and Greenaway, 2004), including those *across* country borders. Grossman and Helpman (1991) explain that cross-border movements of capital and trade affect economic growth through their related knowledge spillovers. Prior work on the role of spillovers also devotes particular attention to inward FDI, in which knowledge flows from foreign multinational enterprises (MNEs) to the host country’s domestic firms are studied (e.g., Feinberg and Majumdar, 2001; Fosfuri et al., 2001). Such research generally assumes that MNEs possess superior firm-specific assets, such as management know-how or technologies, when they enter foreign markets (Dunning, 1981; Hymer, 1976), but they face the challenge of protecting these advantages against other firms in the countries in which they operate (Görg and Greenaway, 2004; Kneller and Pisu, 2007).

In addition to traditional literature on productivity spillovers, an emerging body of research focuses on the effect of spillovers on the export decision of domestic firms, or *export* spillovers (e.g., Aitken et al., 1997; Banga, 2003; Greenaway et al., 2004; Kneller and Pisu, 2007). Domestic firms may be more inclined to engage in export activities if they are exposed to

other economic actors' international activities (Greenaway et al., 2004). Aitken et al. (1997), for instance, note a spillover effect from foreign MNEs to domestic export activity in Mexican manufacturing industries and show that the dominance of foreign MNEs in a particular industry sector increases the probability that domestic firms in that sector also export. Similarly, Greenaway et al. (2004) use U.K. data to show that foreign MNEs' export activities have a positive effect on a domestic firm's export probability.

This study focuses on such export spillover effects, with the assumption that export spillovers should be particularly relevant in the context of new ventures because emerging firms are more likely to benefit from (external) knowledge spillovers than their more established counterparts (Acs et al., 1994; Henderson and Clark, 1990). Whereas in mature firms, external knowledge spillovers may be less important because they must compete with internal knowledge spillovers that result from prior and ongoing operations, the knowledge production function of new ventures likely gets influenced by the input provided by external organizations or activities (Acs et al., 1994). Furthermore, export market entry requires upfront sunk costs for firms to sell products or services in foreign markets, such as the costs associated with establishing distribution and logistic channels and acquiring information about the tastes of foreign customers and market structures (Greenaway et al., 2004; Requena-Silvente, 2005). These sunk costs are higher for new ventures compared with their more established counterparts, because they confront resource constraints more directly (Requena-Silvente, 2005). Accordingly, new ventures are more likely to depend on and benefit from external spillovers.

To understand the mechanisms of how spillovers occur across country borders, extant research identifies different spillover channels, specifically with respect to the case of inward FDI. First, market access spillovers occur through commercial links between foreign MNEs and

local suppliers, which give the local suppliers preferential access to new technological capabilities and foreign customers' product design and quality preferences (Aitken et al., 1997; Barrell and Pain, 1997; Blomström and Kokko, 1998). Second, a demonstration or imitation effect prompts domestic firms to copy foreign MNEs' organizational practices, either through formal interfirm collaborations or more informal channels (Wang and Blomström, 1992). Third, when local employees gain important skills while working for a foreign MNE, a training effect transfers those skills to other organizations (Fosfuri et al., 2001). Fourth, foreign entrants may increase local competition by, for example, infusing new technologies into the local market and acting as competitive catalysts (Barrell and Pain, 1997; Cantwell, 1989; Chuang and Lin, 1999; Glass and Saggi, 1998). For the purpose of this research, we argue that these different channels of cross-border spillovers may clarify how not only inward FDI but also other sources of knowledge spillovers—such as outward FDI and international trade—influence a country's proportion of export-oriented new ventures.

New ventures' export orientation and entrepreneurship spillovers

In addition to examining the antecedents of new ventures' export orientation, we examine whether export-oriented new ventures generate spillovers that affect a country's economic activity, particularly with regard to the creation of new businesses within the country's borders. This focus on *entrepreneurship* spillovers matches recent research that argues entrepreneurial activity (i.e., new business creation) results from the exploitation of knowledge that incumbent firms have not fully appropriated or commercialized (Acs et al., 2006, 2007). Specifically, when an economic agent with a new idea cannot convince decision makers within the firm to pursue the idea, the agent may start a new business in an attempt to appropriate the new knowledge. This new knowledge thus spills over from the agent to a new business in which it gets

commercialized (Audretsch and Keilbach, 2004). Hence, a country's total level of entrepreneurial activity represents an important *outcome* of spillover effects. Similarly, we extend existing literature by suggesting that new business creation may result from spillovers from not only incumbent (large) firms but also other new ventures; in particular, we argue that export-oriented new ventures present a source of spillovers that may affect the emergence of additional new businesses in the country.

HYPOTHESES

Inward FDI and the proportion of export-oriented new ventures

Foreign MNEs (through inward FDI) may act as catalysts of new ventures' export orientation for several reasons. First, foreign MNEs can facilitate exports among new ventures through the direct channel established when the latter serve as suppliers or subcontractors for the MNEs. Commercial linkages with foreign MNEs thus provide new ventures with knowledge about new technological developments and foreign market conditions; over time, this knowledge may prompt new ventures to export (Blomström and Kokko, 1998). Foreign MNEs can also pave the way for new ventures to enter the same export markets, either because the MNEs have created adequate transport infrastructures or because they disseminate knowledge about specific foreign markets that new ventures can use directly. Second, demonstration effects may lead new ventures to use foreign MNEs as role models for their own decision to engage in exporting (Powell and DiMaggio, 1991). Third, spillover effects from foreign MNEs may take place when new ventures acquire relevant human capital. It is difficult for foreign MNEs to lock in their human capital (Djankov and Hoekman, 1999; Dunning, 1981; Fosfuri et al., 2001), but because they often require a skilled labor force, they organize training for local employees. When those employees move away and start their own businesses, the internationalization skills they gained

while working for the foreign affiliate spill over to new ventures (Gerschenberg, 1987). Fourth, inward FDI infuses new technologies in host countries (Barrell and Pain, 1997), and foreign affiliates might replace inefficient firms in the host country (Narula and Marin, 2003). The increased competition should provide local start-ups with the capabilities and need to expand the geographical scope of their activities; that is, the increase in competition that occurs as a result of foreign entry may prompt new ventures to expand their horizons and engage in export activities.

Hypothesis 1: A country's inward FDI relates positively to its proportion of export-oriented new ventures.

In addition, spillover effects may be more pronounced in higher-income versus lower-income countries. The exploitation of spillovers relates to a country's structural characteristics, especially its absorptive capacity (Durham, 2004; Görg and Greenaway, 2004). Spillover effects from inward FDI materialize more easily when the host country has a minimum stock of human capital or level of economic development (Blomström et al., 1994; Borensztein et al., 1998). Extant literature suggests that when the technology gap between the investing country and the host country is not too large—which indicates firms in the host country have sufficient capacity to absorb advanced technologies—the host economy can benefit from positive spillovers (Borensztein et al., 1998; Görg and Greenaway, 2004). Similarly, we reason that lower-income countries may have limited capacity (e.g., human capital) to absorb exporting knowledge provided by foreign MNEs. Furthermore, in lower-income countries, positive spillovers from inward FDI to new ventures' export orientation may be hampered because inward FDI contributes to the development of scale economies and thus to the economic activities of larger, incumbent firms rather than those of new ventures (Acs et al., 1994; Wennekers et al., 2005).

Hypothesis 1A: The positive spillover effect from a country's inward FDI to the export orientation of its new ventures is more pronounced in higher-income versus lower-income countries.

Outward FDI and the proportion of export-oriented new ventures

Although literature on the impact of FDI on a host country's economic activities focuses mostly on spillover effects stemming from inward rather than outward FDI, domestic MNEs should also affect a country's proportion of export-oriented new ventures (Blomström and Kokko, 1998). The presence of these domestic MNEs in foreign countries may familiarize foreign customers with common business practices in the MNEs' home country, which could create a pull effect (Nagel, 2003). Furthermore, the rationale for the spillover effects of domestic MNEs to new ventures parallels arguments associated with foreign MNEs (Blomström and Kokko, 1998). First, spillovers may occur if a domestic MNE adapts its products to local conditions abroad and shares this adaptation with its suppliers (e.g., new ventures) in its home country (Aitken et al., 1997). Second, the spillovers obtained through demonstration, training, and competition effects, as outlined in the argumentation leading up to Hypothesis 1, may work in a similar fashion for domestic MNEs. For example, in terms of the training effect, a manager of a foreign subsidiary may return to the home country and become an (export-oriented) entrepreneur (Cantwell and Hodson, 1991; Kogut and Chang, 1991). Third, the structural changes that take place in the new ventures' home country because of the wider presence of domestic MNEs (i.e., when there is more outward FDI) may positively influence new ventures' export orientation. Specifically, an increase in outward FDI should shift the home country toward economic activities that entail greater productivity (Blomström and Kokko, 1998); this increased productivity may then force new ventures to increase the overall quality of their products, which ultimately should increase their propensity to export.

Hypothesis 2: A country's outward FDI relates positively to its proportion of export-oriented new ventures.

Similar to the argumentation used for the effect of inward FDI, we also speculate that the beneficial spillovers from outward FDI to new ventures' export orientation materialize more easily in higher- versus lower-income countries. That is, lower-income economies may lack the capacity to absorb spillovers from outward FDI, because their new ventures have relatively lower levels of human capital, which they need to engage in exports (Bloodgood et al., 1994), or they may participate in low-technology sectors for which export opportunities are limited (Durham, 2004; Görg and Greenaway, 2004).

Hypothesis 2A: The positive spillover effect from a country's outward FDI to the export orientation of its new ventures is more pronounced in higher-income versus lower-income countries.

International trade and the proportion of export-oriented new ventures

In the previous hypotheses, we posit that FDI, both inward and outward, offers an important source of knowledge spillovers; we now consider how a country's level of international trade may affect its proportion of export-oriented new ventures. We thus extend prior research that indicates a link between international trade (i.e., export and import) and a country's productivity, based on the transfer of knowledge across country borders (Findlay, 1984; Grossman and Helpman, 1991; Sjöholm, 1996). For the purpose of this study, we hypothesize that a country's levels of export and import represent two additional sources of knowledge spillovers that influence new ventures' export orientation.

A country's overall export level should have a positive effect on its proportion of export-oriented new ventures, particularly through the demonstration effect (Greenaway et al., 2004). That is, simple imitation may play an important role in shaping new ventures' decision to export

when they are surrounded by many other firms that engage in export activities. Similarly, the positive relationship between a country's export level and the proportion of export-oriented new ventures mirrors institutional theory that suggests firm behavior results from mimetic isomorphism, or economic actors' tendency to imitate decisions or practices of peers (Powell and DiMaggio, 1991).

Spillovers stemming from a country's level of export should also be significant for new ventures because they minimize the challenge of assessing the costs and benefits associated with export activities (Johanson and Vahlne, 1990). When new ventures come in contact with existing exporters, they gain information about how to become a successful exporter more easily, which diminishes their uncertainty regarding the pros and cons of exporting (Burpitt and Rondinelli, 2000; Ogbuehi and Longfellow, 1994). For example, information that foreign customers provide to incumbent suppliers regarding how to facilitate the production of goods and services they plan to buy could spill over to new ventures through formal partnerships with exporting firms (e.g., strategic alliances) or more informal channels (e.g., trade associations, publications) (De Clercq et al., 2005; Zahra et al., 2000). The previously mentioned training effect may also be relevant in this context (Fosfuri et al., 2001); economic actors who directly or indirectly participate in exporting activities should be stimulated to enter foreign markets when they establish their own companies (McDougall et al., 1994). A final mechanism that may explain the positive relationship between a country's overall level of export and the proportion of its export-oriented new ventures refers to existing relationships between domestic suppliers and foreign customers, which may create a sense of familiarity among foreign customers regarding the country in which new ventures operate and its business practices in particular (Blomström and Kokko, 1998;

Nagel, 2003). This familiarity may increase new ventures' anticipation of success when they consider the possibility of export activities.

Hypothesis 3: A country's export level relates positively to its proportion of export-oriented new ventures.

Again, and similar to the arguments given for the spillovers from FDI, we expect that the positive externalities from a country's overall export levels to the export orientation of its new ventures may be constrained in lower-income countries because of their limited absorptive activity, as reflected in their low levels of human capital and the nature of their industry structure (e.g., few high value-added sectors).

Hypothesis 3A: The positive spillover effect from a country's export level to the export orientation of its new ventures is more pronounced in higher-income versus lower-income countries.

We also posit a positive effect between a country's level of import activity and its proportion of export-oriented new ventures. Import activity reflects the amount of knowledge exchange that takes place between domestic producers and foreign suppliers. Prior research on the spillover effects of import mainly focuses on the role of technology transfer; empirical evidence demonstrates that imports provide an important source for the transfer of new technologies across country borders (e.g., Blalock and Veloso, 2005; Coe and Helpman, 1995; Feinberg and Majumdar, 2001; Glass and Saggi, 1998). We extend this research by arguing that spillover effects from imports relate not only to technology transfer but also to other types of knowledge that may induce export activities. New ventures could benefit from their country's import activities if a foreign producer exchanges knowledge about its home market as a sales tool for existing customers (Coe and Helpman, 1995). If such knowledge spills over to a country's new ventures through collaborations with and exposure to more knowledgeable

domestic players, the new ventures obtain a better understanding of the foreign producers' specific country context and thus achieve a better position from which to find foreign customers. In short, foreign producers may reveal information about their own country's unique characteristics as a sales tool, in which case this knowledge accumulates indirectly within the country in which the new ventures operate. Over time, accumulated knowledge about particular countries should decrease uncertainty related to undertaking business activities in foreign countries and enhance the proportion of export-oriented new ventures.

Hypothesis 4: A country's import level relates positively to its proportion of export-oriented new ventures.

Based on similar reasoning with respect to the role of export spillovers from FDI and export, we speculate that the spillovers from import are more pronounced in higher- versus lower-income countries.

Hypothesis 4A: The positive spillover effect from a country's import level to the export orientation of its new ventures is more pronounced in higher-income versus lower-income countries.

Export-oriented new ventures and total level of entrepreneurial activity

Finally, we expect that the extent to which a country's new ventures are oriented toward exports is not only a consequence of spillover effects but also provides a specific source of spillovers that influences the emergence of new businesses in the country. That is, the nature of early-stage activity itself can be an important source of spillovers (Parker, 2005). In making this claim, we draw from literature that emphasizes the role of macro-level factors to explain cross-country differences in entrepreneurship (Noorderhaven et al., 2004; Verheul et al., 2002). Specifically, previous literature highlights the role of demand-side factors (e.g., country's industrial structure) and supply-side factors (e.g., skills and preferences) in shaping

entrepreneurs' willingness or ability to act on new business opportunities and create the opportunities for such start-up activity. A specific supply factor that influences the emergence of new businesses within a country may be the export orientation of its (existing) new ventures. First, exporting new ventures have preferential access to knowledge related to foreign markets and technologies (Autio et al., 2000; Hessels, 2007; Zahra et al., 2000), and this knowledge may generate novel insights into unexploited opportunities for new businesses (De Clercq et al., 2005; Shane and Venkataraman, 2000). Second, new ventures focusing on export may act as extraordinary role models for aspiring entrepreneurs (Davidsson and Honig, 2003). Consistent with the premises underlying institutional theory, individual economic actors may imitate the behavior of highly visible and successful peers, including export-oriented new ventures (Powell and DiMaggio, 1991). Such imitation may then provide support and legitimacy to entrepreneurship as a career choice, resulting in the creation of more new businesses within the country.

Hypothesis 5: A country's proportion of export-oriented new ventures relates positively to its (subsequent) total level of entrepreneurial activity.

METHODOLOGY

Data and Sample

We draw data from various sources. To determine a country's proportion of export-oriented new ventures and total level of entrepreneurial activity (i.e., dependent variables), we collect information from the Global Entrepreneurship Monitor (GEM; Reynolds et al., 2005). Various organizations (e.g., WTO, OECD, UN, and Eurostat) publish international comparative statistics about exports for many countries, but virtually no official international comparative export statistics relate specifically to new ventures. In this respect, the GEM initiative fills an

important gap by providing a harmonized measure of new ventures' export orientations across countries. For our independent variables, we draw data about a country's FDI from the Foreign Direct Investment database maintained by the United Nations Conference on Trade and Development (UNCTAD) and gather information about each country's export and import levels from the World Bank. Finally, we include several control variables in our models and obtain these data from several sources, including the Global Competitiveness Report and the World Competitiveness Yearbook.

In essence, our data set includes annual data pertaining to 34 countries over a four-year period (2002–2005). The sample of included countries is limited to those that participated in GEM during 2002–2005.² Furthermore, because not all countries participated in GEM in each year and because we note missing data for some independent variables, our analyses are based on 80 observations distributed across 34 countries. Finally, we assign countries to higher- or lower-income categories on the basis of their overall prosperity.³

Measures

Dependent variables

We measure *total level of (early-stage) entrepreneurial activity (2002–2005)* using GEM's TEA index,⁴ which assesses the proportion of a country's population between the ages of 18 and 64 years who are either in the start-up phase or manage/own a business that is less than

² The countries are Argentina, Australia, Belgium, Brazil, Canada, Chile, China, Denmark, Finland, France, Germany, Greece, Hong Kong, Hungary, Iceland, India, Ireland, Israel, Italy, Japan, Korea, Mexico, Netherlands, New Zealand, Norway, Poland, Slovenia, South Africa, Spain, Sweden, Switzerland, Thailand, United Kingdom, and United States.

³ Specifically, following the classification used by the World Bank, the lower-income category includes "low-income economies," "lower-middle-income economies," and "upper-middle-income economies," while the higher-income category includes "high-income economies."

⁴ The TEA (total early-stage entrepreneurial activity) index is the most widely known index generated by GEM (Minniti et al., 2006; Reynolds et al., 2005).

42 months (i.e., three and a half years) of age.⁵ The TEA index thus assesses, in a given year, the total level of (early-stage) entrepreneurial activity within a country, irrespective of its nature. Reynolds et al. (2005) provide empirical support for the validity of the TEA index by comparing it with national administrative data on firm birth rates and support its reliability by calculating the correlation of countries' TEA rates over different years. The TEA is based on information collected through adult population surveys conducted by telephone or face-to-face.

To measure the *proportion of export-oriented new ventures (2002–2005)*, we consider the percentage of a country's (early-stage) entrepreneurs (as defined by the TEA index) involved in substantial export activity. Specifically, we assess the proportion of new ventures, relative to the total number of new ventures, that stated that at least 26% of their customers were located in foreign countries (Reynolds et al., 2005).⁶ With this unique measure, the GEM project provides a first attempt to create cross-country data pertaining to the extent to which new ventures orient toward exports. As one of their defining characteristic, international new ventures are international at their inception (Knight and Cavusgil, 2004; Oviatt and McDougall, 1997). Because of the challenge associated with observing a firm's activities at its inception, extant research typically defines international new ventures pragmatically as those that make foreign market commitments within a relatively long period after their founding, such as six or eight years (Coviello and Jones, 2004; Oviatt and McDougall, 1997). Furthermore, to capture international activity at the time of inception, researchers must define the exact point at which the business was founded (Katz and Gartner, 1988; Reynolds and Miller, 1992). In this regard, Oviatt and McDougall (1997) suggest that the time of business founding occurs when the first

⁵ We count those engaged in both activities in a given year only once (Reynolds et al., 2005).

⁶ Our choice to include only new ventures with a substantial focus on exports (i.e., more than 25% foreign customers) is guided by previous studies in international entrepreneurship, in which high-level exporters are commonly defined as having export sales of 25% or more (Moen, 2002).

serious planning for the business takes place. Accordingly, our measure of new ventures' export orientation includes entrepreneurs that are currently involved in the start-up processes of their venture or have recently gone through this process. Our measure also matches recent research that suggests it is important to take into account a firm's very early phases when studying international new ventures (Coviello, 2006; Moen, 2002). Finally, extant research indicates that foreign market entry by new ventures often takes place within three years of the firm's establishment (Autio et al., 2000; McDougall and Oviatt, 2000; Rennie, 1993). Thus, our definition of new ventures' export orientation includes ventures that are as old as three and half years, which seems appropriate.

Independent variables

Inward FDI (1995-2004) reflects the percentage of a country's inward flow of foreign capital relative to its gross fixed capital formation. *Outward FDI (1995-2004)* equals the percentage of a country's outward flow of capital relative to its gross fixed capital formation. We draw both measures from UNCTAD's World Investment Report.

We use the percentage of a country's exports of goods and services relative to its gross domestic product (GDP) to measure a country's *export level (1995-2004)*, which we obtain from the World Development Indicators database, provided by the World Bank. This measure is skewed toward larger and older firms, which undertake the vast majority of export activity (in terms of value added). Particularly in lower-income countries, the GDP created by new ventures, let alone the amount of their export activity, typically is not recorded in official statistics (Reynolds et al., 2005; Sternberg and Wennekers, 2005). Therefore, it seems unlikely that the added value created by the export activities of new ventures, as captured in our GEM-based measure of new ventures' export orientation, would be recorded in the official statistics about

countries' export levels.⁷ Hence, a positive correlation between export as a percentage of GDP and our measure of the proportion of export-oriented new ventures is by no means straightforward. Similarly, we measure a country's *import level (1995–2004)* as the percentage of a country's imports of goods and services relative to its GDP. This measure is also drawn from the World Development Indicators database.

Control variables

To account for alternative explanations for the variation of both of our dependent variables (i.e., proportion of export-oriented new ventures and total level of entrepreneurial activity) across countries, we include several control variables. Consistent with the eclectic framework of entrepreneurship (Verheul et al., 2002), we classify these controls into two categories: (1) demand-side factors that reflect the presence of entrepreneurial opportunities through market demand and (2) supply-side factors that entail the skills and preferences of a country's population toward new business creation.

In terms of demand-side factors, we consider *employment share in manufacturing* and *employment share in services (2000)* to represent a country's economic structure, which may influence the level and nature of the country's early-stage activity (Verheul et al., 2002). We draw this measure from the World Competitiveness Yearbook. In addition, we use a *lower-income country dummy* to reflect a country's overall prosperity, which may influence the level and nature of its new venture activities (Verheul et al., 2002); we code this dummy as 1 when the country belongs to the "low-income economies", "lower-middle-income economies" or the "upper-middle-income economies" according to the World Bank classification of countries by income. To assess the annual percentage change in a country's GDP, a dynamic measure of a

⁷ Part of the TEA index relates to nascent entrepreneurs, which have not yet started their business (Reynolds et al., 2005); thus, for this group of entrepreneurs, official export statistics certainly do not capture (expected) export activity.

country's overall prosperity, we use *economic growth (2002–2005)*, based on data from the World Economic Outlook database, provided by the International Monetary Fund. Finally, our measure of *company–university cooperation (2001)* assesses (on a seven-point Likert scale) the technology transfer between companies and universities and reflects a source of technological resources for entrepreneurs. This measure emerges from the World Competitiveness Yearbook.

In terms of supply-side factors, *ease of access to loans (2001)*, measured on a seven-point Likert scale and drawn from the Global Competitiveness Report, reflects the extent to which new ventures have easy access to financial resources to support their activities. Furthermore, *tertiary education (1997)*, also drawn from the Global Competitiveness Report, pertains to a country's gross tertiary enrollment rate.

For the estimation of a country's proportion of export-oriented new ventures, we include three additional control variables: *Gross domestic product (logarithm) (2002-2005)*, drawn from the World Development Indicators database, reflects the size of a country's home market. *Inflation rate (2002-2005)*, obtained from the World Economic Outlook Database, reflects increases in consumer price levels (annual percentage changes) that make it harder for economic actors to engage in export activity (domestically, inflation often coincides with wage compensation, but such compensation is less likely at the international trade level). *Change in exchange rate (2002–2005)*, drawn from Economic History Services (and supplemented by information from OANDA.com), is the percentage change of a country's national currency in U.S. dollars. When the exchange rate increases, products become relatively more expensive for foreign buyers, which may hinder new ventures' export orientation. Finally, we include *time dummies* to control for cyclical changes in the global economic environment that may influence the level and nature of entrepreneurial activity within countries.

Analysis

We test our hypotheses using regression analysis. For the prediction of a country's proportion of export-oriented new ventures, we employ different time lags for the independent and control variables. First, because knowledge spillovers may take some time before they materialize (Jaffe and Trajtenberg, 1998) and because the four independent variables—*inward FDI, outward FDI, export, and import*—fluctuate heavily over time, we average the four variables over the years $t-1$ to $t-6$. Second, we include the cyclical variables, *economic growth, inflation rate, and exchange rate*, contemporaneously with the dependent variables, and we capture the remaining cyclical variation by the time dummies. Third, the remaining seven controls—*employment share of manufacturing, employment share of services, lower-income country dummy, company–university cooperation, ease of access to loans, tertiary education, and log of GDP*—reflect structural characteristics of an economy and thus change only slowly over time. Accordingly, we include them as time-invariant variables in the empirical analysis.⁸ Finally, for the prediction of a country's total level of entrepreneurial activity, we use a one-year time lag of the “proportion of export-oriented new ventures” variable.

RESULTS

In Table 1, we display the correlations among the study variables. The correlations between the proportion of export-oriented new ventures and the four sources of cross-border spillovers (*inward FDI, outward FDI, export, and import*) are significant and positive; however, high correlation coefficients mark the four independent variables, particularly between a country's export and import levels (0.98), which raises concerns about multicollinearity (Greene,

⁸ Including these time-invariant independent variables makes the use of fixed effects superfluous, because the time-invariant independent variables can explain structural country differences. Because this approach requires fewer independent variables (i.e., 7 instead of 34 country dummies), we can estimate the model coefficients more efficiently.

2004). The correlation between export and import is so high that their effects cannot be separated in a single regression model. Therefore, we calculate the sum of export and import and label this variable “total international trade.”⁹

Insert Table 1 about here

In Table 2, we present some descriptive statistics for the study’s key variables in higher- versus lower-income countries. As we might expect, the total level of entrepreneurial activity is greater in lower-income countries, whereas the proportion of export-oriented new ventures is greater in higher-income countries. Furthermore, levels of FDI and international trade are greater in higher-income versus lower-income countries, which reflects the latter's poor integration into the world economy. In particular, the low level of outward FDI for lower-income countries is striking; they have only recently begun to engage in outward FDI (UNCTAD, 2006).

Insert Table 2 about here

The results of the regressions predicting a country’s proportion of export-oriented new ventures (i.e., export spillover hypotheses) appear in Table 3. First, Model 1 includes only the control variables and reveals that the proportion of export-oriented new ventures is influenced positively by the country’s employment share in manufacturing and services but negatively by GDP (logged) and the inflation rate. Second, Models 2a-b to 4a-b summarize the results when we enter the various sources of export spillovers (inward FDI, outward FDI, and international trade) into separate models. Specifically, Models 2a–4a do not discriminate between higher- and lower-income countries (to test Hypotheses 1–4), and Models 2b–4b multiply each of the sources

⁹ To assess the separate effects of export and import in the same model, we include a “surplus in international trade” variable, which equals the difference between a country’s export and import levels, in Model 5 (Table 3).

of knowledge spillovers with a dummy variable that reflects whether a country belongs to the higher- or lower-income category (to test Hypotheses 1A–4A).¹⁰

Model 2a indicates no effect of inward FDI on the proportion of export-oriented new ventures and thus a lack of support for Hypothesis 1. However, Model 2b reveals that this lack of effect may be explained by the opposite role that inward FDI plays in higher- versus lower-income countries. Specifically, whereas inward FDI has a positive effect on the proportion of export-oriented new ventures in higher-income countries, its effect is negative in those with lower incomes. This finding provides partial support for Hypothesis 1A, in that we did not anticipate the negative effect for lower-income countries. Furthermore, Model 3a shows a positive effect of outward FDI on the proportion of export-oriented new ventures (in support of Hypothesis 2), and this positive effect manifests itself only in higher-income countries (in support of Hypothesis 2A). Similarly, international trade has a positive effect on the proportion of export-oriented new ventures (Model 4a), which is only present in higher-income countries (Model 4b), in tentative support of Hypotheses 3–4 and 3A–4A.

For a more rigorous test of the export spillover hypotheses, in Model 5, we include the three sources of export spillovers simultaneously, as well as the “surplus in international trade” variable to separate the effects of export versus import. The results show positive effects of outward FDI and total international trade in higher-income countries and a negative effect of inward FDI in lower-income countries. The surplus in international trade variable remains insignificant in both types of countries.

¹⁰ Likelihood ratio tests show that the improvement of the model fit is significant for inward FDI (Model 2b versus Model 2a) but not significant for outward FDI and total international trade. Nevertheless, we observe substantial differences between the coefficients for higher- and lower-income countries for both outward FDI and international trade. We also perform a likelihood ratio test to compare Model 5 with a specification that does not distinguish between effects for the two country classifications. The likelihood ratio value for lower-income countries (not reported) is -245.0, whereas that of Model 5 is -237.6 (see Table 3). Thus, the test statistic equals 14.8. Because the critical value at the 1% level is 13.3 (4 degrees of freedom), the test shows that allowing for different effects for higher- and lower-income countries significantly improves the model fit.

Insert Table 3 about here

Finally, in Table 4, we assess the effect of a country's proportion of export-oriented new ventures on its total level of entrepreneurial activity.¹¹ Model 6, which includes only the controls, shows that a country's economic growth and tertiary education enrollment rate positively influence total entrepreneurial activity, whereas employment share in manufacturing has a negative effect. Model 7 also shows that the proportion of export-oriented new ventures does not have significant effect, but as Table 3 and our hypotheses suggest, this variable is not exogenous. In particular, the log of GDP (i.e., size of the home market) has a strong impact on the proportion of export-oriented new ventures, and therefore, the ordinary least squares estimates in Model 7 likely are biased (Greene, 2004). Accordingly, in Model 8, we estimate a country's total level of entrepreneurial activity using the instrumental variable estimation technique (Greene, 2004).¹² Consistent with our expectations in Hypothesis 5, we find a positive, albeit weak, effect of a country's proportion of export-oriented new ventures on its total level of entrepreneurial activity ($p = 0.06$).¹³ Furthermore, we note that the inclusion of insignificant variables in our model creates a small upward bias in our standard errors. For example, when we exclude the year dummies—which do not appear in the tables for parsimony—we find that the significance level of the proportion of export-oriented new ventures in Model 8 changes to 0.04,

¹¹ The number of observations in Table 4 ($N = 75$) differs from that in Table 3 ($N = 80$). The one-year time lag used in Table 4 results in a loss of observations for the proportion of export-oriented new ventures variable, but Table 4 also "gains" observations for which a spillover variable (i.e., FDI, international trade) was missing in Table 3.

¹² In Model 8, the number of instruments equals the number of endogenous explanatory variables (i.e., 1), so the model is exactly identified (Greene, 2004). As a robustness test, we tried several alternative estimations, with FDI and the trade variables as additional instruments. All estimations support the validity of the applied instruments, and the coefficient for the proportion of export-oriented new ventures variable remains similar to that reported in Model 8 (Table 4).

¹³ We test Hypothesis 7 with a one-tailed test, because the presence of a negative effect of early-stage export activity on total entrepreneurial activity does not seem likely. Also, only 12 of the 75 data points used in Table 4 belong to lower-income countries, so a distinction between countries is not feasible.

which further corroborates Hypothesis 7. The relatively weak effect of a country's proportion of export-oriented new ventures on its total entrepreneurial activity may be partially due to our use of a one-year time lag in Table 4; because data about a country's export-oriented new ventures were collected by the GEM as recently as 2002, only a limited number of data points are available for this variable, and the use of longer time lags is not feasible.

DISCUSSION

Extant literature suggests that firms' entry into foreign markets can be very difficult, especially for new ventures that lack necessary resources, such as first-hand information about foreign tastes and distribution channels (Autio et al., 2000; Eriksson et al., 1997; McDougall and Oviatt, 2000). We extend literature that typically examines the role of individual- or firm-level factors on new ventures' international activities by considering the effect of macro-level (i.e., country) variables. To this end, we rely on knowledge spillover literature to argue that cross-country differences with respect to the proportion of export-oriented new ventures may be the result of a country's openness to cross-border activities (Grosman and Helpman, 1991), as reflected in its level of FDI (both inward and outward) and international trade (export and import). In addition, we consider a country's proportion of export-oriented new ventures not only a consequence of export spillovers but also a driver of entrepreneurship spillovers that contribute to the overall emergence of new businesses within a country's borders (Audretsch and Keilbach, 2004; Parker, 2005).

Our results provide mixed support for the role of export spillover effects in shaping the proportion of export-oriented new ventures. First, in terms of the role of inward FDI, we find a

positive effect in higher-income countries (Model 2b), but this effect disappears when we take other sources of knowledge spillovers into consideration (Model 5). Furthermore, in lower-income countries, inward FDI has a negative rather than positive spillover effect on the proportion of export-oriented new ventures (Models 2b and 5). These findings are revealing, because significant economics literature concentrates on the role of foreign MNEs in creating economic prosperity within host countries (e.g., Barrell and Pain, 1997) or increasing domestic firms' propensity to export (Aitken et al., 1997; Greenaway et al., 2004). However, this source of spillover does not appear to have a positive effect on export orientation among a host country's new ventures, perhaps because the channels for knowledge spillovers from inward FDI seem more relevant to incumbent economic players than to recently created firms. Foreign MNEs may establish commercial linkages with local players that have certain reputations in the host country rather than with novices that lack legitimacy (Podolny, 1993). Alternatively, new ventures may have limited capacity to absorb the knowledge provided by foreign MNEs (Cohen and Levinthal, 1990) and therefore benefit less from their cooperation. In lower-income countries, this lack of absorptive capacity even appears to have a negative effect on the export orientation of new ventures. However, this negative effect should not be interpreted to imply that a country's economic development is hampered when it is exposed to high levels of inward FDI. Rather, the observed negative effect may simply mean that in lower-income countries, knowledge from inward FDI gets more easily absorbed and realized through scale economies by larger firms and thus diverted away from export activities undertaken by new ventures (van Stel et al., 2005). We acknowledge that these explanations are somewhat speculative; further research should assess in more detail the intermediate mechanisms through which new ventures benefit, or fail to benefit,

from inward FDI, as well as how these mechanisms may differ in higher- versus lower-income countries.

Second, the positive influence of a higher-income country's outward FDI on its proportion of export-oriented new ventures (Models 3b and 5) is revealing in light of the argument, upheld by some researchers, that outward FDI can harm a country's economic prosperity by transferring local production and employment to foreign countries (e.g., Jones, 1996). Our study indicates that in higher-income countries, outward FDI may benefit economic activities by stimulating new ventures' export orientation. This positive spillover, as we hypothesized, may occur because domestic MNEs in foreign markets create pull effects (Nagel, 2003), from which domestic new ventures can benefit. However, we also find that the positive export spillover effect is absent in lower-income countries, possibly because they lack the capacity, in terms of both human capital and technology, to absorb the associated knowledge fully within their new ventures (Blomström et al., 1994; Borensztein et al., 1998; Görg and Greenaway, 2004). Overall, the different results for the spillover effects of outward FDI across higher- and lower-income countries provides a nuanced view of the beneficial role of outward FDI for domestic firms (Blomström and Kokko, 1998; Popovici, 2005).

Third, the results in Model 5 show a positive spillover effect of international trade on the proportion of export-oriented new ventures in higher-income countries—an effect stronger than that of outward FDI. Although we have argued that the channels through which export spillovers occur generally work in similar ways when they stem from international trade versus FDI (e.g., through commercial linkages or demonstration effects), new ventures may consider MNEs more “distant” economic actors. According to institutional theory, economic actors tend to imitate the behavior and practices to which they can relate most directly (Powell and DiMaggio, 1991).

Consequently, an exporting decision may be influenced more by the exposure to “simple” international trade rather than to complex FDI activities. We also note, however, that similar to the case of outward FDI, we find no evidence for such a positive export spillover effect of international trade in lower-income countries, perhaps again because of the limited absorptive capacity in these countries (Durham, 2004; Görg and Greenaway, 2004).

Fourth and finally, we find support for the spillover effect of a country’s proportion of export-oriented new ventures on a country’s total level of entrepreneurial activity. Export activity by new ventures may provide successful role models for aspiring entrepreneurs and thus function as catalysts for new business creation (Davidsson and Honig, 2003; De Clercq and Arenius, 2006). In this sense, we identify a particular type of entrepreneurship spillover that stems from export activity (Parker, 2005). This finding also extends prior research that seeks to understand the determinants of a country’s level of entrepreneurship (e.g., Gavron et al., 1998; Noorderhaven et al., 2004; Storey, 1999; Thurik and Wennekers, 2004; van Stel et al., 2005). To the best of our knowledge, our study is the first to examine the link between the type and level of a country’s early-stage entrepreneurial activity. The type of early-stage activity that entrepreneurs choose clearly has important implications for an economy’s well-being (Baumol, 1990). Our study suggests that an important mechanism through which new ventures affect economic prosperity at the country level may emerge through the positive spillover effect of new ventures’ export orientation on the subsequent emergence of more new businesses within the country’s borders.

Limitations and Future Research

Although this study provides important insights into what determines a country’s proportion of export-oriented new ventures (and total level of entrepreneurial activity), it also

includes some limitations. These limitations, in turn, open avenues for future research. First, we focus on only one particular aspect of “productive” activity among new ventures (Baumol, 1990), namely, the extent to which they engage in substantial export activity. Although export represents an important dimension of early-stage international activities (e.g., Burpitt and Rondinelli, 2000; Johanson and Vahlne, 1990), it would be interesting to examine knowledge spillover effects on other facets of international involvement, such as foreign licensing, franchising, or even FDI (Eriksson et al., 1997). Furthermore, the vast body of research on the impact of technology spillovers on economic growth (e.g., Blalock and Veloso, 2005; Feinberg and Majumdar, 2001; Glass and Saggi, 1998) offers a means for entrepreneurship researchers to include alternative dimensions of productive activities (e.g., innovation) that result from FDI and international trade. Such an approach would provide a more encompassing view of how countries’ openness to FDI and international trade influences new ventures’ potential contribution to economic prosperity.

Second, our data set covers only a relatively short period of time, particularly with regard to the variables drawn from GEM, so our analyses are largely static. Additional research would benefit greatly from longitudinal data that span a longer period of time and thus incorporate dynamic elements into the hypothesized relationships. In particular, further research could use time lags greater than a year to examine the spillover effect of new ventures’ export orientation on long-term entrepreneurial activity, because such spillovers may manifest themselves more strongly over time.

Third, in the theory and hypotheses sections, we discuss several channels through which spillovers may occur for new ventures that aspire to engage in export activities (e.g., commercial linkages, prior employment with foreign firms). However, we do not empirically measure these

channels. Although the intangible nature of export spillovers makes an empirical assessment of the channels through which spillovers operate challenging (Greenaway et al., 2004), research should provide more insight into the specific effects generated by various types of spillover channels on new ventures' export orientation. Moreover, the importance of different spillover channels may be contingent on the specific source of the spillovers (e.g., FDI versus international trade).

Fourth, because we focus on aggregate country-level spillover effects, we may have omitted some important industry-level effects. Literature on technology spillovers traditionally focuses on the industry level (e.g., Bernstein and Nadiri, 1988; Cohen and Klepper, 1996), including a large body of research examining whether spillovers within versus between industries are more effective for economic growth (e.g., Frenken et al., 2007; Glaeser et al., 1992; Jacobs, 1969; van Stel and Nieuwenhuijsen, 2004). Similarly, in the context of our study, new ventures' involvement in export activities may depend on knowledge flows from other companies active in the same sector of the economy. By ignoring industry-specific factors, we implicitly assume that the mechanisms through which export spillovers work for new ventures are identical across industries. Additional research could examine the extent to which the strength of spillover effects on new ventures' export practices depends on important industry characteristics, such as maturity level or competition. Finally, researchers could compare the effect of vertical spillovers (i.e., between suppliers and buyers within an industry) versus horizontal spillovers (i.e., between equals across industries) on new ventures' export decisions.

Implications

This study also offers some practical implications. First, entrepreneurs located in higher-income countries who want to become important players in the international arena should locate

in areas where other international players are concentrated, especially those that engage in outward FDI and international trade. From a country-level perspective, governments that hope to encourage export activities among new ventures may benefit from creating geographical zones specifically reserved for internationally oriented firms (Din, 1994). Our findings imply that such zones in higher-income countries may help reduce the costs encountered by new ventures when they break into foreign markets.

Second, governments traditionally focus on stimulating export activity among domestic firms and attracting inward FDI to generate economic growth (Ghauri and Oxelheim, 2003; Greenaway et al., 2004; Molnar, 2003). Furthermore, even when national instruments for promoting outward FDI exist, they tend to be part of developed countries' policy toward poorer countries (Hessels and Prince, 2005). Our study suggests that in higher-income countries, domestic economies may benefit if governments also promote outward FDI. An increased level of outward FDI, combined with international trade, increases the extent to which new ventures engage in export activities, which ultimately could foster economic prosperity (Hessels and van Stel, 2007).

Third, the lack of positive export spillovers in lower-income countries suggests that in addition to stimulating FDI and international trade, governments should stimulate the capacity for the economy, and new ventures in particular, to absorb and exploit the knowledge associated with these efforts, with respect to both the human capital of its entrepreneurial base (e.g., requisite skills to engage in export activity) and the structure of its economy (e.g., technology-based activities that lend themselves better to exporting). Because in lower-income countries, inward FDI may naturally contribute more to the development of scale economies in larger firms

rather than in new ventures (Wennekers et al., 2005), efforts could be undertaken to also channel the knowledge provided by foreign MNEs toward new ventures in these countries.

Conclusion

We examine the role of a country's foreign direct investment and international trade as sources of spillover effects on new ventures' export orientation and, subsequently, as a means to spur its total level of entrepreneurial activity. Our study highlights that new ventures' export orientation indeed functions as a catalyst for new business creation within a country's borders and that such an export orientation is itself influenced by a country's levels of FDI and international trade, albeit to varying degrees in higher- and lower-income countries. Overall, literature on spillovers provides a useful lens for studying macro-level antecedents and outcomes of the extent to which a country's new ventures are export oriented. We hope then that this research leads to the further investigations of the fundamental mechanisms by which a country's posture, in terms of its export orientation, may affect the nature and outcomes of its entrepreneurial undertakings.

* $p < .05$; ** $p < .01$.

^a The indicated correlation refers to the *lagged* value ($t - 1$) of a country's proportion of export-oriented new ventures compared with its total level of entrepreneurial activity, consistent with our analysis in Table 4.

Note: The variables inward FDI, outward FDI, export, and import are averaged over the years $t-1$ to $t-6$.

Table 2: Descriptive statistics for dependent and independent variables, by level of economic development

Higher-Income Countries (N=55)								
	TEA	% Export- Oriented New Ventures	Inward FDI	Outward FDI	Export	Import	Total International Trade	Surplus in International Trade
Mean	6.6	18.3	21.7	22.9	42.0	39.8	81.8	2.2
Standard deviation	3.2	8.2	17.8	19.1	28.2	26.7	54.6	5.2
Minimum	1.48	0.0	0.49	1.00	10.6	9.4	20.0	-8.7
Maximum	14.5	43.2	66.5	56.7	143.0	137.7	280.7	14.4
Lower-Income Countries (N=25)								
	TEA	% Export- Oriented New Ventures	Inward FDI	Outward FDI	Export	Import	Total International Trade	Surplus in International Trade
Mean	12.2	10.0	16.7	2.2	25.6	23.9	49.5	1.69
Standard deviation	6.1	8.6	7.2	3.1	12.7	12.5	24.9	4.0
Minimum	2.5	0.95	2.9	-0.74	9.4	11.2	20.6	-4.9
Maximum	27.3	32.5	31.9	12.1	63.0	64.4	127.4	10.9

Notes: TEA is the number of (early-stage) entrepreneurs as a percentage of the adult population; % export-oriented new ventures is the number of (early-stage) entrepreneurs stating that 26% or more of their customers are foreign as a percentage of the total (early-stage) entrepreneurs; and inward FDI, outward FDI, export, and import are averaged over the years t-1 to t-6.

Table 3: Estimates of a country's proportion of export-oriented new ventures (N = 80)
