Abstract

According to Buchanan and Congleton (1998), the generality principle in politics blocks special interests. Consequently, the generality principle should thereby promote economic efficiency. This study tests this hypothesis on wage formation and labor markets, by investigating whether generality defined as state neutrality could explain employment performance among OECD countries during 1970-2003. We identify three types of non-neutrality as concerns unemployment: the level or degree of government interference in the wage bargaining process over and above legislation which facilitate mutually beneficial wage agreements, the constrained bargaining range (meaning the extent to which the state favors or blocks certain outcomes of the bargaining process), and the cost shifting (which relates to state interference shifting the direct or indirect burden of costs facing the parties on the labor market). Our overall hypothesis is that non-neutrality or non-generality increases unemployment rates. The empirical results from the general conditional model suggest that government intervention and a constrained bargaining range clearly increase unemployment, while a few of the cost shifting variables have unexpected effects. The findings thus give some, but not unqualified, support for the generality principle as a method to promote economic efficiency.

Keywords: generality, state neutrality, efficiency, unemployment, wage bargaining, cost shifting, OECD

* We wish to thank participants at the Public Choice Society meeting in San Antonio, Texas, March 2008, for valuable comment on an earlier draft.

1. Introduction

Buchanan and Congleton (1998) advocate the introduction of a *generality principle* in political decision-making.¹ Through such a principle, they argue, legislation will “apply to all persons independently of membership to in a dominant coalition or an effective interest group”. In other words, generality will promote impartiality and state neutrality. Presumably this will also promote economic efficiency since the enforcement of the generality principle will both block wasteful rent-seeking activities and harmful interventions into markets and civil society.²

In this study we test this hypothesis on wage formation and labor markets, by investigating whether generality defined as state neutrality could explain employment performance among OECD countries during 1970-2003. To our knowledge such an empirical test of the economic consequences of the generality principle or state neutrality has not been done before.

We identify three, partly overlapping, types of non-neutrality as concerns unemployment. These include the level or degree of government interference in the wage bargaining process over and above legislation which facilitate mutually beneficial wage agreements, the constrained bargaining range (meaning the extent to which the state favors or blocks certain outcomes of the bargaining process), and the cost shifting (which relates to state interference shifting the direct or indirect burden of costs facing the parties on the labor market).

To test the effects of the enforcement of the generality principle on wage formation and labor markets may perhaps be particularly interesting, since much of the literature and standard textbooks in labor economics almost as a postulate regard all labor markets to be in need of regulations that favor the sellers of labor and their organizations, i.e. workers and labor unions. Hence, according to this literature the state should *not* be

¹ See also Buchanan (1993a; 1993b) and Congleton (1997).

² In the case of fiscal policies Berggren (2000), however, argues that the generality principle should be augmented with a requirement that “public expenditures as a share of GDP may not increase above the average share of the preceding ten years” in order to minimize the risk of fiscal explosion.

neutral on the market if economic efficiency and employment should be promoted (e.g. Kaufman and Hotchkiss, 2002). In most, at least in the European, OECD countries this turns also out to be the actual practice.

In contrast, our overall hypothesis is thus that non-generality or non-neutrality increases unemployment rates. To our knowledge such an investigation of a negative relationship between state neutrality and level of unemployment has not been conducted systematically before.

We will start by discussing the generality principle, state neutrality and labor market policies in more details in section 2. The data is described in Section 3. The empirical model is formulated in Section 4 and the results are presented in Section 5. The summary of our findings is discussed in Section 6.

2. Generality, State Neutrality, Interventionism and Labor Market Policies

In essence, the generality principle stipulates that the state should be impartial or neutral. According to Buchanan and Congleton (1998) legitimate state action should not discriminate for or against any person or group. With generality the state would treat all citizens equally.

It should be noted, however, that the generality principle or state neutrality does not imply non-interventionism or limited government *per se*.³ Their argument “is about the constitutional structure of those sectors of social interaction that are politicized; it is not directly about drawing some borderline between these (public) sectors and the private (market) sectors” (p. 147) The point is rather that government action which adheres to the generality principle will be efficient since it discourages the natural tendency of majoritarian democracies to give incentives to special interest to engage in rent-seeking

³ As in a competing interpretation of state neutrality which states that the that the state should not interfere in the private spheres of individuals. See Trachtenberg (2001) for a more philosophical critique of the Buchanan-Congleton perspective.

activities. Moreover, they believe that this would also promote the efficiency of the policies adopted and, by implication, economic efficiency in general. (p. 15)

In this study we test this hypothesis on wage formation and labor markets, by investigating whether generality defined as state neutrality could explain employment performance among OECD countries during 1970-2003. The term “state neutrality” is employed in the study as impartiality of the state in labor market related issues. A neutral state does not in policy formation or in legislation one-sidedly favor, or support, one party. Furthermore, according to our interpretation, the government should also refrain from intervening – directly or indirectly – in the wage bargaining process. This means that general or neutral legislation primarily would facilitate for employers and employees, unions and employers associations, to come to mutually beneficial wage agreements, regardless of the outcomes of those agreements.

Perhaps a bit surprisingly to most readers, such a view on state neutrality has in fact been a core idea in the Nordic labor market model for more than hundred years. Already in 1898 the major players on the Danish labor market, both unions and employers organizations, made an over-arching agreement for how to deal with industrial disputes, bargaining, wage setting etc, without state involvement. Sweden followed in 1906, and later in 1938, with similar agreements. Both Norway and, perhaps to a lesser extent, Finland followed in their steps. (Nycander, 2000; 2002)

Event though there may have been shorter or longer periods of state partisanship, this ideology of state neutrality is still a living tradition in all of these countries, shared not only by the parties on the labor market themselves but also by practically all political parties across the political spectrum. For example, in 1999 the social democratic minister of labor market relations Mona Sahlin, presently the leader of the party, clearly stated that a well-functioning system of wage formation rests on the notion of state neutrality.⁴

⁴ Swedish Government, *Regeringens proposition* 1999/2000:32

This is a stark contrast to the practice in both the Continental and the South-European countries, but interestingly enough a similarity to the Anglo-Saxon models. In the latter case, however, individual contracts instead of collective agreements dominate (see e.g. Bamber, Lansbury and Wailes, 2004; Freyssinet and Seifert, 2001; Slomp, 1998).

There are at least four distinct reasons why such a contractual system may be advantageous compared to a more regulated system:

Firstly, it provides opportunities to flexibly adapt wages and benefits to the varying conditions occurring in different companies, sectors, branches and regions of the economy. Secondly, a contractual system thus promotes pluralism and experimentation, which in turn encourage learning and efficiency. If and when new and better ways of organizing various activities or wage setting occur these may easily spread to other parts of the economy. Thirdly, state neutrality gives the actors or partners on the labor market full responsibility for their own agreements, whether good or bad, without accommodat- ing actions from the state. Fourthly, state neutrality, as argued by Buchanan and Congleton, blocks special interests and rent-seeking activities by labor unions and employ- ers organizations. All in all, such a system may work more like competitive markets in general where supply and demand, experimentation and innovation, and voluntary con- tracts provide price signals for the efficient allocation of resources, including labor (Hayek, 1945; 1978; 1980).

Taken together is thus our hypothesis that state neutrality will be beneficial to effi- ciency, the creation of new jobs and employment. We will test the hypothesis by study- ing the effects of the three types of non-neutrality identified above.

Below we develop a model in which these three main factors, or categories, are believed to affect unemployment. These factors are measured by indicators derived from earlier research. The first main category concerns direct *Government involvement* in the labor market over and above legislation which facilitate for unions and employers associa- tions, employers and employees, to come to mutually beneficial wage agreements. Two variables are included in this category. The first, Government involvement in the wage

bargaining process (Government involvement index) has often been analyzed in relation to wage inequalities and been used as a wage-setting measure in earlier research. However, this measure has not been specifically employed to analyze state neutrality. The variable is measured as a time-varying index (1-15) that measures increasing government involvement. For instance, 1 (one) implies that the state is completely uninvolved in the wage bargaining process, whereas increases of the index imply increasing government involvement, such as government extension of collective agreements, enforcement of cost of living adjustment, national wage schedules etc (see Appendix 1). Some but perhaps not all of these indicate non-neutrality.

The second variable in this category measures if there exists a minimum wage law in a specific country and in a certain year, which clearly is a breach of state neutrality. This is a dummy variable that can vary over time (0,1), and which measures only the presence a state-imposed law that sets the wages at a minimum level. Thus, it does not measure the very level or ratio of minimum wages over time or across countries. Some countries, such as Sweden or the other Nordic countries, do not apply minimum wage laws, while this is common in e.g. Mediterranean countries (FedEE, 2005).

The second category, *Constrained bargaining range*, meaning the extent to which the state favors or blocks certain outcomes of the bargaining process, is in the present article represented by one single indicator, namely *Employment protection*. The variable captures the strictness of employment protection laws on a scale 0-2, with increasing strictness. Employment protection often takes several forms but includes e.g. limitations of dismissals, or employer's freedom to assign tasks etc. to employees. (Nickell et al., 2005). However, it is in many instances hard to separate state-imposed employment protection regulated by law, from those various agreements and measures of employment security that often are negotiated or regulated in collective agreements. More specifically, even though the employment protection variable is used as an indicator of increasing difficulty for an employer to dismiss an employee, any general employment protection indicator should probably be taken as a more or less a compact acronym for protection regulated in legislation as well as in collective agreements or customary practice etc. Thus, even if the variable in this particular circumstance is used as an indicator

of non-neutrality – i.e. constrained bargaining range – it is acknowledged by the authors that the variable in many instances actually may measure agreements that *de facto* are negotiated without any government-imposed bargaining range. Still, it is quite clear that such “voluntary” nation-wide agreements about employment protection would not have occurred without supporting legislation of other kinds.⁵

The last category *Cost shifting* relates to non-neutral state interference shifting the direct or indirect burden of costs facing the parties on the labor market, between the parties or perhaps to a third party such as the state itself. Here, five related variables are employed to indicate the degree of cost shifting. Firstly, *Unemployment qualifying condition* measures the time needed to qualify for benefit. The longer the time to qualify, the more of the cost associated with unemployment is carried by the individual and not by another or third party. Similarly, the variable *Unemployment benefit duration* is an indicator of how long an unemployed person is entitled for unemployment benefit. As with the first variable, this naturally varies strongly across economies and over time. The longer the benefit duration, it is thought, the more of the costs for unemployment is carried by for instance a third party such as the state. A third and closely related variable, *Unemployment benefit waiting*, measures the time a person must wait to start receiving benefit after becoming unemployed. This variable would indicate the longer the waiting period for benefit after becoming unemployed, the lower the cost for another or third party.

Two more variables are included in the non-neutral category of cost shifting and they refer more to the overall or general generosity in the social security system, *Unemployment* and *Sickness benefit generosity*, respectively. Both variables represent measures that take in several dimensions over the generosity of unemployment or sickness benefits, and they include benefit levels as well as the ratio of the working force actually insured in the system(s). It should be noted that both of these generosity indicators are

⁵ For a discussion, see OECD Employment Outlook (1999). As also discussed by e.g. Buchele and Christiansen (1999), this measure is complicated and lacks some detail since it does not necessarily take into account the full force of restrictions on employers since much protection is negotiated in collective agreements rather than by government regulations.

not necessarily correlated – a high score on the unemployment generosity variable does not automatically imply that the score on the Sickness variable is high.⁶

4. Data

The data used in this study cover 18 OECD countries observed for the period 1970-2003. Countries included are Australia, Austria, Belgium, Canada, Denmark, Finland, France, Germany (West Germany), Ireland, Italy, Japan, Netherlands, New Zealand, Norway, Sweden, Switzerland, United Kingdom, and the United States. The variables in the analysis relate to institutional and regulatory factors, as well as to welfare and economic incentive variables. The data is derived from previous research and assembled from different databases (for more detailed information, see Appendix 1).

Labor market and related variables are derived from Golden et al. (2002), “Union Centralization among Advanced Industrial Societies: An Empirical Study”. This dataset along with earlier versions has been previously used in analyzing e.g. determinants of wage inequalities; see Wallerstein (1999), Golden and Londrean (2006), and Golden and Wallerstein (2006). The Labour Market Institutions Dataset from Stephen Nickell and Luca Nunziata (2001) has been employed earlier for studying unemployment and wages in the OECD (see for instance Nickell et al., 2001). More general welfare indicators in the analysis are from Huber et al. (2004), Comparative Welfare States Data Set. Moller et al. (2003) e.g. used this data in studying determinants of relative poverty. Finally, Scruggs’ (2005) data, “Welfare States Entitlement Data Set: A Comparative Institutional Analysis of Eighteen Welfare States”, contains, among other things, comprehensive data over qualifying conditions, benefits durations and generosity measures. It has among other things previously been used by Scruggs and Allan (2004) in analyzing welfare state reform in advanced economies. Additionally, empirical data that measures

⁶ For a detailed description, see Scruggs and Allan (2006). Since the different indicators differ even within the one and the same economy, it is hard to find a national coherent strategy for welfare in an overall sense, with exceptions of the Scandinavian countries and the Netherlands; Scruggs och Allan, 2006, p. 69.

self-employment in OECD countries has also been used (Van Stel, 2003). Table 1 presents summary statistics over the variables in the analysis.

The model structure is shown in Table 1 where the dependent variable is the rate of unemployment (UE) measured in percentage of the workforce. The independent variables are classified into 4 groups: (i) government involvement, (ii) constrained bargaining, (iii) cost shifting, and (iv) economic and country specific variables.

The government involvement category includes two variables: government involvement (GOVIN) and minimum wage law (MWLAW). Both the variables are binary variable where the value 1 indicated government involvement in wage setting and presence of minimum wage law in the country. The second category contains only one variable; constrained bargaining range (EP) is defined as three scale degree of employment protection.

The third category, cost shifting, contains 5 indicators including: unemployment qualifying (UEQUAL) condition defined as number of days worked before qualifying for the receipt of such benefit, unemployment duration (UEDUR) defined as the maximum duration of unemployment benefit, unemployment waiting time (UEWAIT) defined as the number of days of unemployment before a payment is made, unemployment benefit (UEMLOY), and sickness benefit (SICKNESS) generosity are indices where a higher value indicate a higher generosity of the system with respect to the respective type of benefit payments.

The last category labeled as control variables are observable economic, time and country specific variables or conditional variables including: a time trend (T) capturing time varying technology and policy effects, industrialization (INDUST) defined as the share of labor force employment in industries, total business ownership rate (TOTRATE) defined in percentage rate, investment rate (KI) defined as percentage of real GDP per employee, gross fixed capital (GROSSK) defined in national currencies, and finally two binary variables indicating location or groups of countries and labor market models of Scandinavian (SCAND) and West European (WESTE), respectively.

Table 1. The model structure.

III. Cost shifting	UEQUAL UEDUR UEWAIT UEMPLOY SICKNESS
<u>C. Control variables:</u>	
IV. Economic and Country Specific Variables	T INDUST TOTRATE KI GROSSK SCAND WESTE

The summary statistics of the data is presented in Table 2. The data is an unbalanced panel data and have a maximum number of 997 observations. The differences in the number of observations (N) by included variables indicates presence of significant number of missing unit data points. In particular data is not available for several East European countries in the 70s and beginning of 80s. We kept the missing observations in the data prior to the estimation to have a better picture of the distribution of each of the labor market indicators.

The mean sample unemployment rate is 6.1% (3.9%) and it varies in the interval of 0 and 24.5% of the labor force. The number in parenthesis is the standard deviation. The minimum value of 0% unemployment rate indicates measurement error. The share of countries with minimum wage law is only 27.8%. The constrained bargaining rate varies in the interval 0.10 and 2.0 with sample mean 1.09 (0.56).

The cost shifting variables show in general more variations. The mean number of days worked prior to being qualified for receiving unemployment benefit is 51.6 (46.6) days.

It varies in the range of 0 days and 208 days. The dispersion in unemployment benefit duration is much higher. The mean sample is 211.5 (342.4) days. It varies in the interval 18 and 999 days. The upper level seems indicate unlimited length of duration. The average number of waiting days before receiving unemployment benefit is 4.8 (4.8) days and it varies between 0 and 18 days. Similarly we observe significant variations in the generosity of both unemployment and sickness benefit systems among the sample countries. The means (std deviations) are 7.39 (2.72) and 8.38 (3.90) respectively.

The time trend variable shows that the countries are on the average observed 18 years and each between 1 and 34 years. The low frequency of observation is attributed to the East European countries. On the average 29.5% (6.3%) of the workforce is employed in the industries. The share varies in the interval 9.9% and 48.4% indicating large difference in degree of industrialization. The mean total business ownership rate is 14.8% (5.9%) and varies in the range of 6.3% and 28.4%. The investment rate as percentage of real GDP per employee is 23.9% with a relatively small dispersion (4.5%), although the range is in the interval 13.4% and 41.0%. A total of 21.7% of the sample data is from Scandinavian countries. The corresponding for West European and other countries are 49.4% and 28.9%, respectively

Table 2. Summary statistics.

Variable	Definition	N	Mean	Std Dev	Minimum	Maximum

5. Empirical Model

The article's aim is to analyze the effects of state neutrality and intervention in the labor market, more specifically its effects on unemployment in OECD. The unemployment model is specified as function of the determinants of unemployment with reference to state neutrality and economic and country specific variables as follows:

$$(1) \quad UE_{it} = \alpha_0 + \alpha_1 GOVINT_{it} + \alpha_2 MWLAW_{it} + \beta EP_{it} + \sum_k \gamma_k COSTSHIFT_{kit} + \sum_m \delta_m ECSV_{mit} + u_{it}$$

where UE is the rate of unemployment for country i in period t, GOVINT and MWLAW are indicators of government intervention in form of involvement in wage formation and introduction of minimum wage law, EP is constrained bargaining, COST-SHIFT is a vector of variables capturing cost shifting from employees to employers, ECSV is a vector of economic and country specific variables capturing heterogeneity in labor market conditions, and the u capture unobservable effects, effects of left out vari-

ables and measurement error in the unemployment rate. The $\alpha, \beta, \delta, \gamma$ are unknown parameters to be estimated which capture the effects of state intervention, constrained bargaining, cost shifting and conditioning economic and welfare variables. Thus, the impacts of government involvement, constrained bargaining and cost shifting effects are analyzed conditioning on the economic and country heterogeneity. By controlling for these conditional variables we reduce the size of unobservable effects and also avoid biased estimated effects of the first categories or determinants of interventions on the rate of unemployment.

6. Empirical Results

Five models are specified and estimated by ordinary least squares method. We have controlled for the time and country effects in the specification of the models. The empirical results are presented Table 3. Some of the 5 models are nested in respect with their specification. Models 1-4 are restricted and unconditional versions of the general Model 5. They are unconditional in the sense that the effect of each category is analyzed by ignoring the effects of remaining categories of variables. In general, the choice of appropriate model could be based on Chow test using the residual sum of square or R^2 from the 5 models. However, due to the missing unit observations the 5 models despite being related differ in the number of observations and thereby not possible to test them against the general model. The four restricted models (Model 1 to 4) are not nested and interpreted individually with respect to the variable categories contribution to the explanation of the variations in the rate of unemployment and fit of the models. We find the general Model 5 as the appropriate model specification and use the remaining 4 models to quantify the contribution of each variable category reflected in the differences in the models R^2 levels. In all models we control for the labor market model (Scandinavian, West European, and Other country groups). In all models the 'Other' country group serves as the reference country group.

The first model includes the first kind of non-neutrality Government involvement and analyzes the effect direct government involvement (GOVIN) in the wage bargaining process as well as the effects of minimum wage laws (MWLAW). As can be observed,

GOVIN shows a negative and statistically insignificant effect on unemployment. MWLAW, on the other hand, displays a positive and significant effect: countries with minimum wage laws display higher unemployment on average. The countries with minimum wage have on the average 0.84% higher unemployment rate than those without. The West European group does not differ from the 'Other' countries group, but the Scandinavian labor market model is found to be superior and it shows lower average (-1.8%) unemployment rate compared with the reference group 'Other' countries.

As mentioned earlier, Model 2 includes one variable, Employment protection, which represents the second kind of non-neutrality, *Constrained bargaining range*. The employment protection variable shows as expected a negative but insignificant effect on unemployment. It is statistically significant only at the 13 percent level. Consequently, this model – or category – alone cannot explain variations in the rate of unemployment. In this model both of the West European and Scandinavian groups differ statistically from the 'Other' countries group. The Scandinavian labor market model is found on the average to have 1.3% lower unemployment than the 'Other' country group, while the corresponding for the West European group is 1.6% higher rate of unemployment.

Model 3, furthermore, represents the third category of non-neutrality *Cost shifting*. Here, three out of five variables show statistically significant effects on unemployment. Unemployment qualification (UEQUAL) and unemployment duration (UEDUR) have no effects. This means that the qualification period and the duration of benefit have no effect on unemployment. We expected the former to reduce the rate of unemployment, while the latter to increase it, everything else given. The unemployment waiting time (UEWAIT) along with unemployment (UEMPLOY) and sickness (SICKNESS) – the last two variables measuring the overall generosity if unemployed or sick – are statistically significant here. We expected a negative relationship between UEWAIT and unemployment rate but a positive relationship between UEMPLOY and SICKNESS. Particularly waiting time and sickness benefit generosity shows interesting relationships since the two variables, contrary to the assumptions in the model, are positive and negative, respectively. This would mean that longer waiting time increases unemployment rate and more generous systems in sickness lowers the unemployment level. This seems counter-intuitive given our hypothesis about neutrality and cost shifting. However, it could be interpreted as a transfer effect: those unemployed for a longer period of time become defined as sick or as early retired. This lowers unemployment since sickness by definition is not treated as unemployment. For every day of extension in the waiting time the unemployment rate increases with 0.29%. An increase in the unemployment generosity scale increases the unemployment rate with 0.20%, while the corresponding change in the sickness benefits reduce unemployment rate with 0.23%, ceteris paribus. The Scandinavian (1.8%) and West European (3.7%) countries have on the average a higher unemployment rate.

Model 4 includes policy-, incentive- and country-related control variables. Nearly all of the variables show significant effects on the rate of unemployment. The coefficient of time trend is positive and statistically significant suggesting that on the average unemployment is increasing by 0.055% every year. The rate of unemployment is a negative function of the share of employment in industries. For every percentage increase in industry's employment share the unemployment is declining with 0.26%. Private business ownership increases the unemployment rate. An increase in investment rate as share of

GDP by 1% reduces unemployment by 0.32%. An increased gross fixed capital formation also reduces unemployment rate. West Europeans have on the average lower unemployment (2.1%) compared to the reference group.

Finally, Model 5 (full model) includes all our categories. The full model does not indicate that direct government involvement has any statistically significant effect on unemployment. Introduction of minimum wages, however, results in a 1.4% increase in unemployment. Consequently, in some instances non-neutrality in the form of *Government involvement* in the labor market and in the wage bargaining process increases unemployment and thus hampers economic efficiency.

Furthermore, non-neutrality in the form of *Constrained bargaining range* – here measured as the degree of employment protection – displays a similar effect. It increases unemployment with 1.9%. Thus, the extent to which the labor market's parties can freely negotiate and come to agreement without state involvement in this regard has a clear effect on the unemployment level.

The last category of non-neutrality, finally, *Cost shifting* shows in the full model a number of some interesting effects. Some variables now become significant and/or received reversed signs. Now unemployment qualification, the time needed to qualify for benefit, becomes statistically significant. This means that longer qualifying waiting periods, the lower the unemployment. Unemployment duration and waiting time do not show any effects on unemployment, but unemployment and sickness benefits have unexpectedly each a negative effect on unemployment. Unemployment benefit has much stronger effect than sickness benefit. The unemployment and sickness benefit indicators clearly show that more generous systems, where the degree of non-neutrality in the form of cost shifting is high – indicating that key direct or indirect burden of costs for the parties on the labor market, or a third party, are higher – has a clear effect on unemployment. However, the effect is clearly negative, which means that on the average, a higher level of cost shifting and non-neutrality reduces unemployment, and hence improves economic efficiency. The same caveats as mentioned above still apply however.

The coefficient of time trend is positive and statistically significant indicating that unemployment is increasing by 0.20% every year. The rate of unemployment is a negative function of the share of employment in industries and the share of private business ownership. For every percentage increase in these variables share the unemployment is declining with 0.12%. An increase in investment rate as share of GDP by 1% reduces unemployment by 0.3%. An increased gross fixed capital formation also reduces unemployment rate. West European and Scandinavian countries have on the average 0.60% and 0.63% lower unemployment than the reference group of 'Other' countries.

7. Summary and conclusions

The empirical results are based on data for 18 OECD countries observed during 1970-2003. We identify three types of non-neutrality as concerns unemployment. These include the level or degree of government involvement in the wage bargaining process over and above legislation which facilitate mutually beneficial wage agreements (and thus preventing certain outcomes in the interest of some parties), the constrained bargaining range (meaning the extent to the state favors or blocks certain outcomes of the bargaining process), and the cost shifting (which relates to state interference shifting the direct or indirect burden of costs facing the parties on the labor market). Our overall hypothesis is that non-neutrality or non-generality increases unemployment rates.

The empirical results from the general conditional model suggest that non-neutrality government intervention and a constrained bargaining range clearly increase unemployment, while a few of the cost shifting variables have unexpected effects. The findings thus give some, but not unqualified, support for the generality principle as a method to promote economic efficiency.
